{8652/0009} {AI95-00137-01} {AI05-0295-1} [Two kinds of aspects of entities can be specified: representation aspects and operational aspects. Representation aspects affect how the types and other entities of the language are to be mapped onto the underlying machine. Operational aspects determine other properties of entities.] 0.1/3

{AI05-0183-1} {AI05-0295-1} [Either kind of aspect of an entity may be specified by means of an `aspect_specification` (see 13.1.1), which is an optional element of most kinds of declarations and applies to the entity or entities being declared. Aspects may also be specified by certain other constructs occurring subsequent to the declaration of the affected entity: a representation aspect value may be specified by means of a representation item and an operational aspect value may be specified by means of an operational item.] 0.2/3

{8652/0009} {AI95-00137-01} There are six kinds of *representation items*: `attribute_definition_clauses` for representation attributes, `enumeration_representation_clauses`, `record_representation_clauses`, `at_clauses`, `component_clauses`, and *representation pragmas*. [ They can be provided to give more efficient representation or to interface with features that are outside the domain of the language (for example, peripheral hardware). ] 1/1

{8652/0009} {AI95-00137-01} An *operational item* is an `attribute_definition_clause` for an operational attribute. 1.1/1

{8652/0009} {AI95-00137-01} [An operational item or a representation item applies to an entity identified by a `local_name`, which denotes an entity declared local to the current declarative region, or a library unit declared immediately preceding a representation pragma in a compilation.] 1.2/1

### *Language Design Principles*

{8652/0009} {AI95-00137-01} {AI05-0295-1} Representation aspects are intended to refer to properties that need to be known before the compiler can generate code to create or access an entity. For instance, the size of an object needs to be known before the object can be created. Conversely, operational aspects are those that only need to be known before they can be used. For instance, how an object is read from a stream only needs to be known when a stream read is executed. Thus, representation aspects have stricter rules as to when they can be specified. 1.a/3

{AI95-00291-02} {AI05-0295-1} Confirming the value of an aspect should never change the semantics of the aspect. Thus `Size = 8` (for example) means the same thing whether it was specified with a representation item or whether the compiler chose this value by default. 1.a.1/3

**Glossary entry:** An aspect is a specifiable property of an entity. An aspect may be specified by an `aspect_specification` on the declaration of the entity. Some aspects may be queried via attributes. 1.a.2/3

### *Syntax*

{8652/0009} {AI95-00137-01} `aspect_clause ::= attribute_definition_clause`  
`| enumeration_representation_clause`  
`| record_representation_clause`  
`| at_clause` 2/1

3       local\_name ::= direct\_name  
           | direct\_name'attribute\_designator  
           | library\_unit\_name

4/1       {8652/0009} {AI95-00137-01} A representation pragma is allowed only at places where an aspect\_clause or compilation\_unit is allowed.

*Name Resolution Rules*

5/1       {8652/0009} {AI95-00137-01} In an operational item or representation item, if the local\_name is a direct\_name, then it shall resolve to denote a declaration (or, in the case of a pragma, one or more declarations) that occurs immediately within the same declarative region as the item. If the local\_name has an attribute\_designator, then it shall resolve to denote an implementation-defined component (see 13.5.1) or a class-wide type implicitly declared immediately within the same declarative region as the item. A local\_name that is a library\_unit\_name (only permitted in a representation pragma) shall resolve to denote the library\_item that immediately precedes (except for other pragmas) the representation pragma.

5.a/1       **Reason:** {8652/0009} {AI95-00137-01} This is a Name Resolution Rule, because we don't want an operational or representation item for X to be ambiguous just because there's another X declared in an outer declarative region. It doesn't make much difference, since most operational or representation items are for types or subtypes, and type and subtype names can't be overloaded.

5.b/1       **Ramification:** {8652/0009} {AI95-00137-01} The visibility rules imply that the declaration has to occur before the operational or representation item.

5.c/1       {8652/0009} {AI95-00137-01} For objects, this implies that operational or representation items can be applied only to stand-alone objects.

*Legality Rules*

6/1       {8652/0009} {AI95-00137-01} The local\_name of an aspect\_clause or representation pragma shall statically denote an entity (or, in the case of a pragma, one or more entities) declared immediately preceding it in a compilation, or within the same declarative\_part, package\_specification, task\_definition, protected\_definition, or record\_definition as the representation or operational item. If a local\_name denotes a [local] callable entity, it may do so through a [local] subprogram\_renaming\_declaration [(as a way to resolve ambiguity in the presence of overloading)]; otherwise, the local\_name shall not denote a renaming\_declaration.

6.a       **Ramification:** The “statically denote” part implies that it is impossible to specify the representation of an object that is not a stand-alone object, except in the case of a representation item like pragma Atomic that is allowed inside a component\_list (in which case the representation item specifies the representation of components of all objects of the type). It also prevents the problem of renamings of things like “P.all” (where P is an access-to-subprogram value) or “E(I)” (where E is an entry family).

6.b       The part about where the denoted entity has to have been declared appears twice — once as a Name Resolution Rule, and once as a Legality Rule. Suppose P renames Q, and we have a representation item in a declarative\_part whose local\_name is P. The fact that the representation item has to appear in the same declarative\_part as P is a Name Resolution Rule, whereas the fact that the representation item has to appear in the same declarative\_part as Q is a Legality Rule. This is subtle, but it seems like the least confusing set of rules.

6.c       **Discussion:** A separate Legality Rule applies for component\_clauses. See 13.5.1, “Record Representation Clauses”.

7/2       {AI95-00291-02} The *representation* of an object consists of a certain number of bits (the *size* of the object). For an object of an elementary type, these are the bits that are normally read or updated by the machine code when loading, storing, or operating-on the value of the object. For an object of a composite type, these are the bits reserved for this object, and include bits occupied by subcomponents of the object. If the size of an object is greater than that of its subtype, the additional bits are padding bits. For an elementary object, these padding bits are normally read and updated along with the others. For a composite object, padding bits might not be read or updated in any given composite operation, depending on the implementation.

- To be honest:** *{AI95-00291-02}* Discontiguous representations are allowed, but the ones we're interested in here are generally contiguous sequences of bits. For a discontiguous representation, the size doesn't necessarily describe the “footprint” of the object in memory (that is, the amount of space taken in the address space for the object). 7.a/2
- Discussion:** *{AI95-00291-02}* In the case of composite objects, we want the implementation to have the flexibility to either do operations component-by-component, or with a block operation covering all of the bits. We carefully avoid giving a preference in the wording. There is no requirement for the choice to be documented, either, as the implementation can make that choice based on many factors, and could make a different choice for different operations on the same object. 7.a.1/2
- {AI95-00291-02}* In the case of a properly aligned, contiguous object whose size is a multiple of the storage unit size, no other bits should be read or updated as part of operating on the object. We don't say this normatively because it would be difficult to normatively define “properly aligned” or “contiguous”. 7.a.2/2
- Ramification:** Two objects with the same value do not necessarily have the same representation. For example, an implementation might represent False as zero and True as any odd value. Similarly, two objects (of the same type) with the same sequence of bits do not necessarily have the same value. For example, an implementation might use a biased representation in some cases but not others: 7.b
- ```
{AI05-0229-1} subtype S is Integer range 1..256;
type A is array(Natural range 1..4) of S
with Pack;
X : S := 3;
Y : A := (1, 2, 3, 4);
```
- The implementation might use a biased-by-1 representation for the array elements, but not for X. X and Y(3) have the same value, but different representation: the representation of X is a sequence of (say) 32 bits: 0..011, whereas the representation of Y(3) is a sequence of 8 bits: 00000010 (assuming a two's complement representation). 7.d
- Such tricks are not required, but are allowed. 7.e
- Discussion:** The value of any padding bits is not specified by the language, though for a numeric type, it will be much harder to properly implement the predefined operations if the padding bits are not either all zero, or a sign extension. 7.f
- Ramification:** *{AI05-0229-1}* For example, suppose S'Size = 2, and an object X is of subtype S. If the machine code typically uses a 32-bit load instruction to load the value of X, then X'Size should be 32, even though 30 bits of the value are just zeros or sign-extension bits. On the other hand, if the machine code typically masks out those 30 bits, then X'Size should be 2. Usually, such masking only happens for components of a composite type for which Pack, Component_Size, or record layout is specified. 7.g/3
- Note, however, that the formal parameter of an instance of Unchecked_Conversion is a special case. Its Size is required to be the same as that of its subtype. 7.h
- Note that we don't generally talk about the representation of a value. A value is considered to be an amorphous blob without any particular representation. An object is considered to be more concrete. 7.i
- {AI05-0112-1}* *{AI05-0295-1}* A representation item *directly specifies a representation aspect* of the entity denoted by the local_name, except in the case of a type-related representation item, whose local_name shall denote a first subtype, and which directly specifies an aspect of the subtype's type. A representation item that names a subtype is either *subtype-specific* (Size and Alignment clauses) or *type-related* (all others). [Subtype-specific aspects may differ for different subtypes of the same type.] 8/3
- To be honest:** *Type-related* and *subtype-specific* are defined likewise for the corresponding aspects of representation. 8.a
- To be honest:** Some representation items directly specify more than one aspect. 8.b
- Discussion:** *{AI05-0229-1}* For example, a pragma Export (see J.15.5) specifies the convention of an entity, and also specifies that it is exported. Such items are obsolescent; directly specifying the associated aspects is preferred. 8.c/3
- Ramification:** Each specifiable attribute constitutes a separate aspect. An enumeration_representation_clause specifies the coding aspect. A record_representation_clause (without the mod_clause) specifies the record layout aspect. Each representation pragma specifies a separate aspect. 8.d
- Reason:** We don't need to say that an at_clause or a mod_clause specify separate aspects, because these are equivalent to attribute_definition_clauses. See J.7, “At Clauses”, and J.8, “Mod Clauses”. 8.e
- {AI05-0112-1}* We give a default naming for representation aspects of representation pragmas so we don't have to do that for every pragma. Operational and representation attributes are given a default naming in 13.3. We don't want any anonymous aspects; that would make other rules more difficult to write and understand. 8.e.1/3
- Ramification:** The following representation items are type-related: 8.f
- enumeration_representation_clause 8.g
 - record_representation_clause 8.h

- 8.i • Component_Size clause
- 8.j/1 • *This paragraph was deleted.* {8652/0009} {AI95-00137-01}
- 8.k • Small clause
- 8.l • Bit_Order clause
- 8.m • Storage_Pool clause
- 8.n • Storage_Size clause
- 8.n.1/2 • {AI95-00270-01} Stream_Size clause
- 8.o/1 • *This paragraph was deleted.* {8652/0009} {AI95-00137-01}
- 8.p/1 • *This paragraph was deleted.* {8652/0009} {AI95-00137-01}
- 8.q/1 • *This paragraph was deleted.* {8652/0009} {AI95-00137-01}
- 8.r/1 • *This paragraph was deleted.* {8652/0009} {AI95-00137-01}
- 8.s • Machine_Radix clause
- 8.t • pragma Pack
- 8.u • pragmas Import, Export, and Convention (when applied to a type)
- 8.v/3 • {AI05-0009-1} pragmas Atomic, Independent, and Volatile (when applied to a type)
- 8.w/3 • {AI05-0009-1} pragmas Atomic_Components, Independent_Components, and Volatile_Components (when applied to a type)
- 8.x • pragma Discard_Names (when applied to an enumeration or tagged type)
- 8.y The following representation items are subtype-specific:
- 8.z • Alignment clause (when applied to a first subtype)
- 8.aa • Size clause (when applied to a first subtype)
- 8.bb The following representation items do not apply to subtypes, so they are neither type-related nor subtype-specific:
- 8.cc • Address clause (applies to objects and program units)
- 8.dd • Alignment clause (when applied to an object)
- 8.ee • Size clause (when applied to an object)
- 8.ff • pragmas Import, Export, and Convention (when applied to anything other than a type)
- 8.gg • pragmas Atomic and Volatile (when applied to an object or a component)
- 8.hh/3 • {AI05-0009-1} pragmas Atomic_Components, Independent_Components, and Volatile_Components (when applied to an array object)
- 8.ii • pragma Discard_Names (when applied to an exception)
- 8.jj • pragma Asynchronous (applies to procedures)
- 8.kk/2 • {AI95-00414-01} pragma No_Return (applies to subprograms)
- 8.ll/3 {AI05-0229-1} While an aspect_specification is not a representation item, a similar categorization applies to the aspect that corresponds to each of these representation items (along with aspects that do not have associated representation items).
- 8.l/3 {8652/0009} {AI95-00137-01} {AI05-0183-1} An operational item *directly specifies* an *operational aspect* of the entity denoted by the `local_name`, except in the case of a type-related operational item, whose `local_name` shall denote a first subtype, and which directly specifies an aspect of the type of the subtype.
- 8.mm/1 **Ramification:** {8652/0009} {AI95-00137-01} The following operational items are type-related:
 - 8.nn/1 • External_Tag clause
 - 8.oo/1 • Read clause
 - 8.pp/1 • Write clause
 - 8.qq/1 • Input clause
 - 8.rr/1 • Output clause
- 9/3 {AI05-0183-1} A representation item that directly specifies an aspect of a subtype or type shall appear after the type is completely defined (see 3.11.1), and before the subtype or type is frozen (see 13.14). If a

representation item or `aspect_specification` is given that directly specifies an aspect of an entity, then it is illegal to give another representation item or `aspect_specification` that directly specifies the same aspect of the entity.

- Ramification:** {8652/0009} {AI95-00137-01} The fact that a representation item (or operational item, see next paragraph) that directly specifies an aspect of an entity is required to appear before the entity is frozen prevents changing the representation of an entity after using the entity in ways that require the representation to be known. 9.a/1
- To be honest:** {AI05-0183-1} The rule preventing multiple specification is also intended to cover other ways to specify representation aspects, such as obsolescent pragma Priority. Priority is not a representation pragma, and as such is neither a representation item nor an `aspect_specification`. Regardless, giving both a pragma Priority and an `aspect_specification` for Priority is illegal. We didn't want to complicate the wording solely to support obsolescent features. 9.b/3
- {8652/0009} {AI95-00137-01} {AI05-0183-1} An operational item that directly specifies an aspect of an entity shall appear before the entity is frozen (see 13.14). If an operational item or `aspect_specification` is given that directly specifies an aspect of an entity, then it is illegal to give another operational item or `aspect_specification` that directly specifies the same aspect of the entity. 9.1/3
- Ramification:** Unlike representation items, operational items can be specified on partial views. Since they don't affect the representation, the full declaration need not be known to determine their legality. 9.c/1
- {AI05-0106-1} {AI05-0295-1} Unless otherwise specified, it is illegal to specify an operational or representation aspect of a generic formal parameter. 9.2/3
- Reason:** Specifying an aspect on a generic formal parameter implies an added contract for a generic unit. That contract needs to be defined via generic parameter matching rules, and, as aspects vary widely, that has to be done for each such aspect. Since most aspects do not need this complexity (including all language-defined aspects as of this writing), we avoid the complexity by saying that such contract-forming aspect specifications are banned unless the rules defining them explicitly exist. Note that the method of specification does not matter: `aspect_specifications`, representation items, and operational items are all covered by this (and similar) rules. 9.d/3
- {AI05-0295-1} For an untagged derived type, it is illegal to specify a type-related representation aspect if the parent type is a by-reference type, or has any user-defined primitive subprograms. 10/3
- Ramification:** {8652/0009} {AI95-00137-01} {AI05-0295-1} On the other hand, subtype-specific representation aspects may be specified for the first subtype of such a type, as can operational aspects. 10.a/3
- Reason:** {AI05-0229-1} {AI05-0295-1} The reason for forbidding specification of type-related representation aspects on untagged by-reference types is because a change of representation is impossible when passing by reference (to an inherited subprogram). The reason for forbidding specification of type-related representation aspects on untagged types with user-defined primitive subprograms was to prevent implicit change of representation for type-related aspects of representation upon calling inherited subprograms, because such changes of representation are likely to be expensive at run time. Changes of subtype-specific representation attributes, however, are likely to be cheap. This rule is not needed for tagged types, because other rules prevent a type-related representation aspect from changing the representation of the parent part; we want to allow specifying a type-related representation aspect on a type extension to specify aspects of the extension part. For example, specifying aspect Pack will cause packing of the extension part, but not of the parent part. 10.b/3
- {8652/0009} {AI95-00137-01} {8652/0011} {AI95-00117-01} {AI95-00326-01} {AI05-0295-1} 11/3
Operational and representation aspects of a generic formal parameter are the same as those of the actual. Operational and representation aspects are the same for all views of a type. Specification of a type-related representation aspect is not allowed for a descendant of a generic formal untagged type.
- Ramification:** {8652/0009} {AI95-00137-01} {AI05-0295-1} Specifying representation aspects is allowed for types whose subcomponent types or index subtypes are generic formal types. Specifying operational aspects and subtype-related representation aspects is allowed on descendants of generic formal types. 11.a/3
- Reason:** {AI05-0295-1} Since it is not known whether a formal type has user-defined primitive subprograms, specifying type-related representation aspects for them is not allowed, unless they are tagged (in which case only the extension part is affected in any case). 11.b/3
- Ramification:** {AI95-00326-01} All views of a type, including the incomplete and partial views, have the same operational and representation aspects. That's important so that the properties don't change when changing views. While most aspects are not available for an incomplete view, we don't want to leave any holes by not saying that they are the same. 11.c/2

- 11.d/3 *{AI05-0083-1}* However, this does not apply to objects. Different views of an object can have different representation aspects. For instance, an actual object passed by reference and the associated formal parameter may have different values for Alignment even though the formal parameter is merely a view of the actual object. This is necessary to maintain the language design principle that Alignments are always known at compile time.
- 12/3 *{AI05-0295-1}* The specification of the Size aspect for a given subtype, or the size or storage place for an object (including a component) of a given subtype, shall allow for enough storage space to accommodate any value of the subtype.
- 13/3 *{8652/0009}* *{AI95-00137-01}* *{AI05-0295-1}* If a specification of a representation or operational aspect is not supported by the implementation, it is illegal or raises an exception at run time.
- 13.1/3 *{AI95-00251-01}* *{AI05-0295-1}* A `type_declaration` is illegal if it has one or more progenitors, and a nonconfirming value was specified for a representation aspect of an ancestor, and this conflicts with the representation of some other ancestor. The cases that cause conflicts are implementation defined.
- 13.a/2 **Implementation defined:** The cases that cause conflicts between the representation of the ancestors of a `type_declaration`.
- 13.b/3 **Reason:** *{AI05-0295-1}* This rule is needed because it may be the case that only the combination of types in a type declaration causes a conflict. Thus it is not possible, in general, to reject the original representation item or `aspect_specification`. For instance:
- 13.c/2
- ```

package Pkg1 is
 type Ifc is interface;
 type T is tagged record
 Fld : Integer;
 end record;
 for T use record
 Fld at 0 range 0 .. Integer'Size - 1;
 end record;
end Pkg1;

```
- 13.d/2 Assume the implementation uses a single tag with a default offset of zero, and that it allows the use of nondefault locations for the tag (and thus accepts representation items like the one above). The representation item will force a nondefault location for the tag (by putting a component other than the tag into the default location). Clearly, this package will be accepted by the implementation. However, other declarations could cause trouble. For instance, the implementation could reject:
- 13.e/2
- ```

with Pkg1;
package Pkg2 is
  type NewT is new Pkg1.T and Pkg1.IfC with null record;
end Pkg2;

```
- 13.f/3 *{AI05-0295-1}* because the declarations of T and Ifc have a conflict in their representation items. This is clearly necessary (it's hard to imagine how Ifc'Class could work with the tag at a location other than the one it is expecting without introducing distributed overhead).
- 13.g/3 *{AI05-0295-1}* Conflicts will usually involve implementation-defined attributes (for specifying the location of the tag, for instance), although the example above shows that doesn't have to be the case. For this reason, we didn't try to specify exactly what causes a conflict; it will depend on the implementation's implementation model and what representation aspects it allows to be changed.
- 13.h/3 **Implementation Note:** *{AI05-0295-1}* An implementation can only use this rule to reject `type_declarations` where one of its ancestors had a nonconfirming representation value specified. An implementation must ensure that the default representations of ancestors cannot conflict.

Static Semantics

- 14 If two subtypes statically match, then their subtype-specific aspects (Size and Alignment) are the same.
- 14.a/3 **Reason:** *{AI05-0295-1}* This is necessary because we allow (for example) conversion between access types whose designated subtypes statically match. Note that most aspects (including the subtype-specific aspects Size and Alignment) may not be specified for a nonfirst subtype. The only language-defined exceptions to this rule are the `Static_Predicate` and `Dynamic_Predicate` aspects.

Consider, for example:

```

package P1 is
  subtype S1 is Integer range 0..2**16-1;
  for S1'Size use 16; -- Illegal!
  -- S1'Size would be 16 by default.
  type A1 is access all S1;
  X1: A1;
end P1;

package P2 is
  subtype S2 is Integer range 0..2**16-1;
  for S2'Size use 32; -- Illegal!
  type A2 is access all S2;
  X2: A2;
end P2;

{AI05-0229-1} procedure Q is
  use P1, P2;
  type Array1 is array(Integer range <>) of aliased S1
    with Pack;
  Obj1: Array1(1..100);
  type Array2 is array(Integer range <>) of aliased S2
    with Pack;
  Obj2: Array2(1..100);
begin
  X1 := Obj2(17)'Unchecked_Access;
  X2 := Obj1(17)'Unchecked_Access;
end Q;

```

14.b

14.c/1

14.d/1

14.e/3

Loads and stores through X1 would read and write 16 bits, but X1 points to a 32-bit location. Depending on the endianness of the machine, loads might load the wrong 16 bits. Stores would fail to zero the other half in any case. 14.f

Loads and stores through X2 would read and write 32 bits, but X2 points to a 16-bit location. Thus, adjacent memory locations would be trashed. 14.g

Hence, the above is illegal. Furthermore, the compiler is forbidden from choosing different Sizes by default, for the same reason. 14.h

The same issues apply to Alignment. 14.i

{8652/0040} {AI95-00108-01} {AI05-0009-1} {AI05-0295-1} A derived type inherits each type-related representation aspect of its parent type that was directly specified before the declaration of the derived type, or (in the case where the parent is derived) that was inherited by the parent type from the grandparent type. A derived subtype inherits each subtype-specific representation aspect of its parent subtype that was directly specified before the declaration of the derived type, or (in the case where the parent is derived) that was inherited by the parent subtype from the grandparent subtype, but only if the parent subtype statically matches the first subtype of the parent type. An inherited representation aspect is overridden by a subsequent `aspect_specification` or representation item that specifies a different value for the same aspect of the type or subtype. 15/3

To be honest: A `record_representation_clause` for a record extension does not override the layout of the parent part; if the layout was specified for the parent type, it is inherited by the record extension. 15.a

Ramification: If a representation item for the parent appears after the `derived_type_definition`, then inheritance does not happen for that representation item. 15.b

{AI05-0009-1} {AI05-0295-1} If an inherited aspect is confirmed by an `aspect_specification` or a later representation item for a derived type, the confirming specification does not override the inherited one. Thus the derived type has both a specified confirming value and an inherited nonconfirming representation value — this means that rules that apply only to nonconfirming representation values still apply to this type. 15.b.1/3

{8652/0040} {AI95-00108-01} {AI95-00444-01} {AI05-0183-1} {AI05-0295-1} In contrast, whether operational aspects are inherited by a derived type depends on each specific aspect; unless specified, an operational aspect is not inherited. When operational aspects are inherited by a derived type, aspects that were directly specified by `aspect_specifications` or operational items that are visible at the point of the derived type declaration, or (in the case where the parent is derived) that were inherited by the parent type from the grandparent type are inherited. An inherited operational aspect is overridden by a subsequent `aspect_specification` or operational item that specifies the same aspect of the type. 15.1/3

- 15.b.2/1 **Ramification:** As with representation items, if an operational item for the parent appears after the `derived_type_`-definition, then inheritance does not happen for that operational item.
- 15.2/2 {AI95-00444-01} When an aspect that is a subprogram is inherited, the derived type inherits the aspect in the same way that a derived type inherits a user-defined primitive subprogram from its parent (see 3.4).
- 15.c/2 **Reason:** This defines the parameter names and types, and the needed implicit conversions.
- 16 Each aspect of representation of an entity is as follows:
- 17 • If the aspect is *specified* for the entity, meaning that it is either directly specified or inherited, then that aspect of the entity is as specified, except in the case of `Storage_Size`, which specifies a minimum.
- 17.a **Ramification:** This rule implies that queries of the aspect return the specified value. For example, if the user writes “`for X'Size use 32;`”, then a query of `X'Size` will return 32.
- 18 • If an aspect of representation of an entity is not specified, it is chosen by default in an unspecified manner.
- 18.a/3 **Ramification:** {8652/0009} {AI95-00137-01} {AI05-0295-1} Note that specifying a representation aspect can affect the semantics of the entity.
- 18.b The rules forbid things like “`for S'Base'Alignment use ...`” and “`for S'Base use record ...`”.
- 18.c **Discussion:** The intent is that implementations will represent the components of a composite value in the same way for all subtypes of a given composite type. Hence, `Component_Size` and record layout are type-related aspects.
- 18.d/3 **Ramification:** {AI05-0083-1} As noted previously, in the case of an object, the entity mentioned in this text is a specific view of an object. That means that only references to the same view of an object that has a specified value for a representation aspect *R* necessarily have that value for the aspect *R*. The value of the aspect *R* for a different view of that object is unspecified. In particular, this means that the representation values for by-reference parameters is unspecified; they do not have to be the same as those of the underlying object.
- 18.1/1 {8652/0040} {AI95-00108-01} If an operational aspect is *specified* for an entity (meaning that it is either directly specified or inherited), then that aspect of the entity is as specified. Otherwise, the aspect of the entity has the default value for that aspect.
- 18.2/3 {AI95-00291-02} {AI05-0295-1} An `aspect_specification` or representation item that specifies a representation aspect that would have been chosen in the absence of the `aspect_specification` or representation item is said to be *confirming*. The aspect value specified in this case is said to be a *confirming* representation aspect value. Other values of the aspect are said to be *nonconfirming*, as are the `aspect_specifications` and representation items that specified them.

Dynamic Semantics

- 19/1 {8652/0009} {AI95-00137-01} For the elaboration of an `aspect_clause`, any evaluable constructs within it are evaluated.
- 19.a/3 **Ramification:** {AI05-0299-1} Elaboration of representation pragmas is covered by the general rules for pragmas in 2.8.

Implementation Permissions

- 20/3 {AI05-0295-1} An implementation may interpret representation aspects in an implementation-defined manner. An implementation may place implementation-defined restrictions on the specification of representation aspects. A *recommended level of support* is defined for the specification of representation aspects and related features in each subclause. These recommendations are changed to requirements for implementations that support the Systems Programming Annex (see C.2, “Required Representation Support”).
- 20.a/3 **Implementation defined:** The interpretation of each representation aspect.
- 20.b/3 **Implementation defined:** Any restrictions placed upon the specification of representation aspects.

- Ramification:** Implementation-defined restrictions may be enforced either at compile time or at run time. There is no requirement that an implementation justify any such restrictions. They can be based on avoiding implementation complexity, or on avoiding excessive inefficiency, for example. 20.c
- {8652/0009} {AI95-00137-01} There is no such permission for operational aspects. 20.c.1/1
- Implementation Advice*
- {AI05-0295-1} The recommended level of support for the specification of all representation aspects is qualified as follows: 21/3
- {AI95-00291-02} {AI05-0295-1} A confirming specification for a representation aspect should be supported. 21.1/3
 - To be honest:** {AI05-0295-1} A confirming representation aspect value might not be possible for some entities. For instance, consider an unconstrained array. The size of such a type is implementation-defined, and might not actually be a representable value, or might not be static. 21.a/3
 - {AI05-0295-1} An implementation need not support the specification for a representation aspect that contains nonstatic expressions, unless each nonstatic expression is a **name** that statically denotes a constant declared before the entity. 22/3
 - Reason:** This is to avoid the following sort of thing: 22.a

```
X : Integer := F(...);
Y : Address := G(...);
for X'Address use Y;
```

 22.b

In the above, we have to evaluate the initialization expression for X before we know where to put the result. This seems like an unreasonable implementation burden. 22.c

The above code should instead be written like this: 22.d

```
Y : constant Address := G(...);
X : Integer := F(...);
for X'Address use Y;
```

 22.e

This allows the expression “Y” to be safely evaluated before X is created. 22.f

The constant could be a formal parameter of mode **in**. 22.g

An implementation can support other nonstatic expressions if it wants to. Expressions of type Address are hardly ever static, but their value might be known at compile time anyway in many cases. 22.h
 - An implementation need not support a specification for the Size for a given composite subtype, nor the size or storage place for an object (including a component) of a given composite subtype, unless the constraints on the subtype and its composite subcomponents (if any) are all static constraints. 23
 - {AI95-00291-02} {AI05-0295-1} An implementation need not support specifying a nonconfirming representation aspect value if it could cause an aliased object or an object of a by-reference type to be allocated at a nonaddressable location or, when the alignment attribute of the subtype of such an object is nonzero, at an address that is not an integral multiple of that alignment. 24/3
 - Reason:** The intent is that access types, type System.Address, and the pointer used for a by-reference parameter should be implementable as a single machine address — bit-field pointers should not be required. (There is no requirement that this implementation be used — we just want to make sure it's feasible.) 24.a/1
 - Implementation Note:** {AI95-00291-02} We want subprograms to be able to assume the properties of the types of their parameters inside of subprograms. While many objects can be copied to allow this (and thus do not need limitations), aliased or by-reference objects cannot be copied (their memory location is part of their identity). Thus, the above rule does not apply to types that merely allow by-reference parameter passing; for such types, a copy typically needs to be made at the call site when a bit-aligned component is passed as a parameter. 24.b/2
 - {AI95-00291-02} {AI05-0295-1} An implementation need not support specifying a nonconfirming representation aspect value if it could cause an aliased object of an elementary type to have a size other than that which would have been chosen by default. 25/3
 - Reason:** Since all bits of elementary objects participate in operations, aliased objects must not have a different size than that assumed by users of the access type. 25.a/2

- 26/3 • *{AI95-00291-02}* *{AI05-0295-1}* An implementation need not support specifying a nonconfirming representation aspect value if it could cause an aliased object of a composite type, or an object whose type is by-reference, to have a size smaller than that which would have been chosen by default.
- 26.a/2 **Reason:** Unlike elementary objects, there is no requirement that all bits of a composite object participate in operations. Thus, as long as the object is the same or larger in size than that expected by the access type, all is well.
- 26.b/2 **Ramification:** This rule presumes that the implementation allocates an object of a size specified to be larger than the default size in such a way that access of the default size suffices to correctly read and write the value of the object.
- 27/3 • *{AI95-00291-02}* *{AI05-0295-1}* An implementation need not support specifying a nonconfirming subtype-specific representation aspect value for an indefinite or abstract subtype.
- 27.a/3 **Reason:** *{AI05-0295-1}* Representation aspects are often not well-defined for such types.
- 27.b/3 **Ramification:** *{AI95-00291-02}* *{AI05-0229-1}* A type with the Pack aspect specified will typically not be packed so tightly as to disobey the above rules. A Component_Size clause or record_representation_clause will typically be illegal if it disobeys the above rules. Atomic components have similar restrictions (see C.6, “Shared Variable Control”).
- 28/3 *{AI95-00291-02}* *{AI05-0295-1}* For purposes of these rules, the determination of whether specifying a representation aspect value for a type *could cause* an object to have some property is based solely on the properties of the type itself, not on any available information about how the type is used. In particular, it presumes that minimally aligned objects of this type might be declared at some point.
- 28.a/2 **Implementation Advice:** The recommended level of support for all representation items should be followed.
- NOTES
- 29/3 1 *{AI05-0229-1}* Aspects that can be specified are defined throughout this International Standard, and are summarized in K.1.
- Incompatibilities With Ada 83*
- 29.a It is now illegal for a representation item to cause a derived by-reference type to have a different record layout from its parent. This is necessary for by-reference parameter passing to be feasible. This only affects programs that specify the representation of types derived from types containing tasks; most by-reference types are new to Ada 95. For example, if A1 is an array of tasks, and A2 is derived from A1, it is illegal to apply a pragma Pack to A2.
- Extensions to Ada 83*
- 29.b/1 *{8652/0009}* *{AI95-00137-01}* Ada 95 allows additional `aspect_clauses` for objects.
- Wording Changes from Ada 83*
- 29.c/1 *{8652/0009}* *{AI95-00137-01}* The syntax rule for `type_representation_clause` is removed; the right-hand side of that rule is moved up to where it was used, in `aspect_clause`. There are two references to “type representation clause” in RM83, both in Section 13; these have been reworded. Also, the `representation_clause` has been renamed the `aspect_clause` to reflect that it can be used to control more than just representation aspects.
- 29.d/2 *{8652/0009}* *{AI95-00137-01}* *{AI95-00114-01}* We have defined a new term “representation item,” which includes all representation clauses and representation pragmas, as well as `component_clauses`. This is convenient because the rules are almost identical for all of them. We have also defined the new terms “operational item” and “operational aspects” in order to conveniently handle new types of specifiable entities.
- 29.e All of the forcing occurrence stuff has been moved into its own subclause (see 13.14), and rewritten to use the term “freezing”.
- 29.f RM83-13.1(10) requires implementation-defined restrictions on representation items to be enforced at compile time. However, that is impossible in some cases. If the user specifies a junk (nonstatic) address in an address clause, and the implementation chooses to detect the error (for example, using hardware memory management with protected pages), then it's clearly going to be a run-time error. It seems silly to call that “semantics” rather than “a restriction.”
- 29.g RM83-13.1(10) tries to pretend that `representation_clauses` don't affect the semantics of the program. One counter-example is the Small clause. Ada 95 has more counter-examples. We have noted the opposite above.
- 29.h Some of the more stringent requirements are moved to C.2, “Required Representation Support”.

Extensions to Ada 95

{AI95-00291-02} **Amendment Correction:** Confirming representation items are defined, and the recommended level of support is now that they always be supported. 29.i/2

Wording Changes from Ada 95

{8652/0009} {AI95-00137-01} **Corrigendum:** Added operational items in order to eliminate unnecessary restrictions and permissions on stream attributes. As part of this, `representation_clause` was renamed to `aspect_clause`. 29.j/2

{8652/0009} {AI95-00137-01} {AI95-00326-01} **Corrigendum:** Added wording to say that the partial and full views have the same operational and representation aspects. Ada 2005 extends this to cover all views, including the incomplete view. 29.k/2

{8652/0040} {AI95-00108-01} **Corrigendum:** Changed operational items to have inheritance specified for each such aspect. 29.l/2

{AI95-00251-01} Added wording to allow the rejection of types with progenitors that have conflicting representation items. 29.m/2

{AI95-00291-02} The description of the representation of an object was clarified (with great difficulty reaching agreement). Added wording to say that representation items on aliased and by-reference objects never need be supported if they would not be implementable without distributed overhead even if other recommended level of support says otherwise. This wording matches the rules with reality. 29.n/2

{AI95-00444-01} {AI05-0005-1} Added wording so that inheritance depends on whether operational items are visible rather than whether they occur before the declaration (we don't want to look into private parts). Also limited operational inheritance to untagged types to avoid anomalies with private extensions (this is not incompatible, no existing operational attribute used this capability). Also added wording to clearly define that subprogram inheritance works like derivation of subprograms. 29.o/3

Incompatibilities With Ada 2005

{AI05-0106-1} **Correction:** Specifying a language-defined aspect for a generic formal parameter is no longer allowed. Most aspects could not be specified on these anyway; moreover, this was not allowed in Ada 83, so it is unlikely that compilers are supporting this as a capability (and it is not likely that they have a consistent definition of what it means if it is allowed). Thus, we expect this to occur rarely in existing programs. 29.p/3

Wording Changes from Ada 2005

{AI05-0009-1} **Correction:** Defined that overriding of an representation aspect only happens for a nonconfirming representation item. This prevents a derived type from being considered to have only a confirming representation item when the value would be nonconfirming if given on a type that does not inherit any aspects of representation. This change just eliminates a wording confusion and ought not change any behavior. 29.q/3

{AI05-0112-1} **Correction:** Defined a default naming for representation aspects that are representation pragmas. 29.r/3

{AI05-0183-1} Added text ensuring that the rules for representational and operational items also apply appropriately to `aspect_specifications`; generalized operational aspects so that they can be defined for entities other than types. Any extensions are documented elsewhere. 29.s/3

{AI05-0295-1} Rewrote many rules to be in terms of "specifying a representation aspect" rather than use of a "representation item". This better separates *how* an aspect is specified from *what* rules apply to the value of the aspect. 29.t/3

13.1.1 Aspect Specifications

{AI05-0183-1} [Certain representation or operational aspects of an entity may be specified as part of its declaration using an `aspect_specification`, rather than using a separate representation or operational item.] The declaration with the `aspect_specification` is termed the *associated declaration*. 1/3

Syntax

```
{AI05-0183-1} aspect_specification ::=
  with aspect_mark [=> aspect_definition] {,
    aspect_mark [=> aspect_definition] }
```

```
{AI05-0183-1} aspect_mark ::= aspect_identifier['Class'] 3/3
```

```
{AI05-0183-1} aspect_definition ::= name | expression | identifier 4/3
```

- 4.a/3 {AI05-0183-1} {AI05-0267-1} The `aspect_specification` is an optional element in most kinds of declarations. Here is a list of all kinds of declarations and an indication of whether or not they allow aspect clauses, and in some cases a short discussion of why (* = allowed, NO = not allowed). Kinds of declarations with no indication are followed by their subdivisions (which have indications).

 - *We also allow `aspect_specifications` on all kinds of bodies, but are no language-defined aspects that may be specified on a body. These are allowed for implementation-defined aspects.*
 - *See above for subprogram bodies and stubs (as these can be declarations).*
 - package_body*
 - task_body*
 - protected_body*
 - package_body_stub*
 - task_body_stub*

protected_body_stub*

{AI05-0267-1} Syntactically, `aspect_specifications` generally are located at the end of declarations. When a declaration is all in one piece such as a `null_procedure_declaration`, `object_declaration`, or `generic_instantiation` the `aspect_specification` goes at the end of the declaration; it is then more visible and less likely to interfere with the layout of the rest of the structure. However, we make an exception for program units (other than subprogram specifications) and bodies, in which the `aspect_specification` goes before the `is`. In these cases, the entity could be large and could contain other declarations that also have `aspect_specifications`, so it is better to put the `aspect_specification` toward the top of the declaration. (Some aspects – such as `Pure` – also affect the legality of the contents of a unit, so it would be annoying to only see those after reading the entire unit.) 4.d/3

Name Resolution Rules

{AI05-0183-1} An `aspect_mark` identifies an aspect of the entity defined by the associated declaration (the *associated entity*); the aspect denotes an object, a value, an expression, a subprogram, or some other kind of entity. If the `aspect_mark` identifies: 5/3

- an aspect that denotes an object, the `aspect_definition` shall be a `name`. The expected type for the `name` is the type of the identified aspect of the associated entity; 6/3
- an aspect that is a value or an expression, the `aspect_definition` shall be an `expression`. The expected type for the `expression` is the type of the identified aspect of the associated entity; 7/3
- an aspect that denotes a subprogram, the `aspect_definition` shall be a `name`; the expected profile for the `name` is the profile required for the aspect of the associated entity; 8/3
- an aspect that denotes some other kind of entity, the `aspect_definition` shall be a `name`, and the `name` shall resolve to denote an entity of the appropriate kind; 9/3
- an aspect that is given by an identifier specific to the aspect, the `aspect_definition` shall be an `identifier`, and the `identifier` shall be one of the identifiers specific to the identified aspect. 10/3

{AI05-0183-1} The usage names in an `aspect_definition` [are not resolved at the point of the associated declaration, but rather] are resolved at the end of the immediately enclosing declaration list. 11/3

{AI05-0183-1} If the associated declaration is for a subprogram or entry, the names of the formal parameters are directly visible within the `aspect_definition`, as are certain attributes, as specified elsewhere in this International Standard for the identified aspect. If the associated declaration is a `type_declaration`, within the `aspect_definition` the names of any components are directly visible, and the name of the first subtype denotes the current instance of the type (see 8.6). If the associated declaration is a `subtype_declaration`, within the `aspect_definition` the name of the new subtype denotes the current instance of the subtype. 12/3

Legality Rules

{AI05-0183-1} If the first freezing point of the associated entity comes before the end of the immediately enclosing declaration list, then each usage name in the `aspect_definition` shall resolve to the same entity at the first freezing point as it does at the end of the immediately enclosing declaration list. 13/3

{AI05-0183-1} At most one occurrence of each `aspect_mark` is allowed within a single `aspect_specification`. The aspect identified by the `aspect_mark` shall be an aspect that can be specified for the associated entity (or view of the entity defined by the associated declaration). 14/3

{AI05-0183-1} The `aspect_definition` associated with a given `aspect_mark` may be omitted only when the `aspect_mark` identifies an aspect of a boolean type, in which case it is equivalent to the `aspect_definition` being specified as `True`. 15/3

{AI05-0183-1} If the `aspect_mark` includes `'Class`, then the associated entity shall be a tagged type or a primitive subprogram of a tagged type. 16/3

- 17/3 {AI05-0183-1} {AI05-0267-1} There are no language-defined aspects that may be specified on a `renaming_declaration`, a `generic_formal_parameter_declaration`, a `subunit`, a `package_body`, a `task_body`, a `protected_body`, or a `body_stub` other than a `subprogram_body_stub`.
- 17.a/3 **Discussion:** Implementation-defined aspects can be allowed on these, of course; the implementation will need to define the semantics. In particular, the implementation will need to define actual type matching rules for any aspects allowed on formal types; there are no default matching rules defined by the language.
- 18/3 {AI05-0183-1} {AI05-0267-1} A language-defined aspect shall not be specified in an `aspect_specification` given on a `subprogram_body` or `subprogram_body_stub` that is a completion of another declaration.
- 18.a/3 **Reason:** Most language-defined aspects (for example, preconditions) are intended to be available to callers, and specifying them on a body that has a separate declaration hides them from callers. Specific language-defined aspects may allow this, but they have to do so explicitly (by defining an alternative Legality Rule), and provide any needed rules about visibility. Note that this rule does not apply to implementation-defined aspects, so implementers need to carefully define whether such aspects can be applied to bodies and stubs, and what happens if they are specified on both the declaration and body of a unit.

Static Semantics

- 19/3 {AI05-0183-1} Depending on which aspect is identified by the `aspect_mark`, an `aspect_definition` specifies:
- 20/3
- a name that denotes a subprogram, object, or other kind of entity;
- 21/3
- an expression, which is either evaluated to produce a single value, or which (as in a precondition) is to be evaluated at particular points during later execution; or
- 22/3
- an identifier specific to the aspect.
- 23/3 {AI05-0183-1} The identified aspect of the associated entity, or in some cases, the view of the entity defined by the declaration, is as specified by the `aspect_definition` (or by the default of True when boolean). Whether an `aspect_specification` *applies* to an entity or only to the particular view of the entity defined by the declaration is determined by the `aspect_mark` and the kind of entity. The following aspects are view specific:
- 24/3
- An aspect specified on an `object_declaration`;
- 25/3
- An aspect specified on a `subprogram_declaration`;
- 26/3
- An aspect specified on a `renaming_declaration`.
- 27/3 {AI05-0183-1} All other `aspect_specifications` are associated with the entity, and *apply* to all views of the entity, unless otherwise specified in this International Standard.
- 28/3 {AI05-0183-1} If the `aspect_mark` includes 'Class, then:
- 29/3
- if the associated entity is a tagged type, the specification *applies* to all descendants of the type;
- 30/3
- if the associated entity is a primitive subprogram of a tagged type *T*, the specification *applies* to the corresponding primitive subprogram of all descendants of *T*.
- 31/3 {AI05-0183-1} {AI05-0229-1} All specifiable operational and representation attributes may be specified with an `aspect_specification` instead of an `attribute_definition_clause` (see 13.3).
- 31.a/3 **Ramification:** The name of the aspect is the same as that of the attribute (see 13.3), so the `aspect_mark` is the `attribute_designator` of the attribute.
- 32/3 {AI05-0229-1} Any aspect specified by a representation pragma or library unit pragma that has a `local_name` as its single argument may be specified by an `aspect_specification`, with the entity being the `local_name`. The `aspect_definition` is expected to be of type Boolean. The expression shall be static.
- 32.a/3 **Ramification:** The name of the aspect is the same as that of the pragma (see 13.1), so the `aspect_mark` is the name of the pragma.

- {AI05-0229-1} In addition, other operational and representation aspects not associated with specifiable attributes or representation pragmas may be specified, as specified elsewhere in this International Standard. 33/3
- {AI05-0183-1} If an aspect of a derived type is inherited from an ancestor type and has the boolean value True, the inherited value shall not be overridden to have the value False for the derived type, unless otherwise specified in this International Standard. 34/3
- {AI05-0183-1} If a Legality Rule or Static Semantics rule only applies when a particular aspect has been specified, the aspect is considered to have been specified only when the `aspect_specification` or `attribute_definition_clause` is visible (see 8.3) at the point of the application of the rule. 35/3
- Reason:** Some rules only apply when an aspect has been specified (for instance, an indexable type is one that has aspect `Variable_Indexing` specified). In order to prevent privacy breaking, this can only be true when the specification of the aspect is visible. In particular, if the `Variable_Indexing` aspect is specified on the full view of a private type, the private type is not considered an indexable type. 35.a/3
- {AI05-0183-1} Alternative legality and semantics rules may apply for particular aspects, as specified elsewhere in this International Standard. 36/3

Dynamic Semantics

- {AI05-0183-1} At the freezing point of the associated entity, the `aspect_specification` is elaborated. The elaboration of the `aspect_specification` includes the evaluation of the `name` or `expression`, if any, unless the aspect itself is an `expression`. If the corresponding aspect represents an `expression` (as in a precondition), the elaboration has no effect; the `expression` is evaluated later at points within the execution as specified elsewhere in this International Standard for the particular aspect. 37/3

Implementation Permissions

- {AI05-0183-1} Implementations may support implementation-defined aspects. The `aspect_specification` for an implementation-defined aspect may use an implementation-defined syntax for the `aspect_definition`, and may follow implementation-defined legality and semantics rules. 38/3
- Discussion:** The intent is to allow implementations to support aspects that are defined, for example, by a `subtype_indication` rather than an `expression` or a `name`. We chose not to try to enumerate all possible `aspect_definition` syntaxes, but to give implementations maximum freedom. Unrecognized aspects are illegal whether or not they use custom syntax, so this freedom does not reduce portability. 38.a/3
- Implementation defined:** Implementation-defined aspects, including the syntax for specifying such aspects and the legality rules for such aspects. 38.a.1/3

Extensions to Ada 2005

- {AI05-0183-1} {AI05-0229-1} {AI05-0267-1} Aspect specifications are new. 38.b/3

13.2 Packed Types

- {AI05-0229-1} [The `Pack` aspect having the value True specifies that storage minimization should be the main criterion when selecting the representation of a composite type.] 1/3

Paragraphs 2 through 4 were moved to Annex J, “Obsolescent Features”.

Static Semantics

- {AI05-0229-1} For a full type declaration of a composite type, the following language-defined representation aspect may be specified: 5/3

- 5.1/3 **Pack** The type of aspect `Pack` is Boolean. When aspect `Pack` is True for a type, the type (or the extension part) is said to be *packed*. For a type extension, the parent part is packed as for the parent type, and specifying `Pack` causes packing only of the extension part.
- 5.a/3 **Aspect Description for Pack:** Minimize storage when laying out records and arrays.
- 5.2/3 If directly specified, the `aspect_definition` shall be a static expression. If not specified (including by inheritance), the aspect is False.
- 5.b/3 **Ramification:** *{AI05-0229-1}* The only high level semantic effect of specifying the `Pack` aspect is potential loss of independent addressability (see 9.10, “Shared Variables”).]

Implementation Advice

- 6 If a type is packed, then the implementation should try to minimize storage allocated to objects of the type, possibly at the expense of speed of accessing components, subject to reasonable complexity in addressing calculations.
- 6.a.1/2 **Implementation Advice:** Storage allocated to objects of a packed type should be minimized.
- 6.a/3 **Ramification:** *{AI05-0229-1}* Specifying the `Pack` aspect is for gaining space efficiency, possibly at the expense of time. If more explicit control over representation is desired, then a `record_representation_clause`, a `Component_Size` clause, or a `Size` clause should be used instead of, or in addition to, the `Pack` aspect.
- 6.1/2 *{AI95-00291-02}* If a packed type has a component that is not of a by-reference type and has no aliased part, then such a component need not be aligned according to the `Alignment` of its subtype; in particular it need not be allocated on a storage element boundary.
- 7/3 *{AI05-0229-1}* The recommended level of support for the `Pack` aspect is:
- 8
- For a packed record type, the components should be packed as tightly as possible subject to the `Sizes` of the component subtypes, and subject to any `record_representation_clause` that applies to the type; the implementation may, but need not, reorder components or cross aligned word boundaries to improve the packing. A component whose `Size` is greater than the word size may be allocated an integral number of words.
- 8.a **Ramification:** The implementation can always allocate an integral number of words for a component that will not fit in a word. The rule also allows small component sizes to be rounded up if such rounding does not waste space. For example, if `Storage_Unit` = 8, then a component of size 8 is probably more efficient than a component of size 7 plus a 1-bit gap (assuming the gap is needed anyway).
- 9/3
- *{AI05-0009-1}* For a packed array type, if the `Size` of the component subtype is less than or equal to the word size, `Component_Size` should be less than or equal to the `Size` of the component subtype, rounded up to the nearest factor of the word size.
- 9.a **Ramification:** If a component subtype is aliased, its `Size` will generally be a multiple of `Storage_Unit`, so it probably won't get packed very tightly.
- 9.b/3 **Implementation Advice:** The recommended level of support for the `Pack` aspect should be followed.

Wording Changes from Ada 95

- 9.c/3 *{AI95-00291-02}* *{AI05-0229-1}* Added clarification that the `Pack` aspect can ignore alignment requirements on types that don't have by-reference or aliased parts. This was always intended, but there was no wording to that effect.

Extensions to Ada 2005

- 9.d/3 *{AI05-0229-1}* Aspect `Pack` is new; `pragma Pack` is now obsolescent.

Wording Changes from Ada 2005

- 9.e/3 *{AI05-0009-1}* **Correction:** Fixed so that the presence or absence of a confirming `Component_Size` representation clause does not change the meaning of the `Pack` aspect.

13.3 Operational and Representation Attributes

{8652/0009} {AI95-00137-01} [The values of certain implementation-dependent characteristics can be obtained by interrogating appropriate operational or representation attributes. Some of these attributes are specifiable via an `attribute_definition_clause`.] 1/1

Language Design Principles

In general, the meaning of a given attribute should not depend on whether the attribute was specified via an `attribute_definition_clause`, or chosen by default by the implementation. 1.a

Syntax

```
attribute_definition_clause ::=
  for local_name'attribute_designator use expression;
| for local_name'attribute_designator use name; 2
```

Name Resolution Rules

For an `attribute_definition_clause` that specifies an attribute that denotes a value, the form with an expression shall be used. Otherwise, the form with a name shall be used. 3

For an `attribute_definition_clause` that specifies an attribute that denotes a value or an object, the expected type for the expression or name is that of the attribute. For an `attribute_definition_clause` that specifies an attribute that denotes a subprogram, the expected profile for the name is the profile required for the attribute. For an `attribute_definition_clause` that specifies an attribute that denotes some other kind of entity, the name shall resolve to denote an entity of the appropriate kind. 4

Ramification: For example, the `Size` attribute is of type *universal_integer*. Therefore, the expected type for `Y` in “`for X'Size use Y;`” is *universal_integer*, which means that `Y` can be of any integer type. 4.a

Discussion: For attributes that denote subprograms, the required profile is indicated separately for the individual attributes. 4.b

Ramification: For an `attribute_definition_clause` with a name, the name need not statically denote the entity it denotes. For example, the following kinds of things are allowed: 4.c

```
for Some_Access_Type'Storage_Pool use Storage_Pool_Array(I);
for Some_Type'Read use Subprogram_Pointer.all; 4.d
```

Legality Rules

{8652/0009} {AI95-00137-01} {AI05-0183-1} An `attribute_designator` is allowed in an `attribute_definition_clause` only if this International Standard explicitly allows it, or for an implementation-defined attribute if the implementation allows it. Each specifiable attribute constitutes an operational aspect or aspect of representation; the name of the aspect is that of the attribute. 5/3

Discussion: For each specifiable attribute, we generally say something like, “The ... attribute may be specified for ... via an `attribute_definition_clause`.” 5.a

The above wording allows for `T'Class'Alignment`, `T'Class'Size`, `T'Class'Input`, and `T'Class'Output` to be specifiable. 5.b

A specifiable attribute is not necessarily specifiable for all entities for which it is defined. For example, one is allowed to ask `T'Component_Size` for an array subtype `T`, but “`for T'Component_Size use ...`” is only allowed if `T` is a first subtype, because `Component_Size` is a type-related aspect. 5.c

For an `attribute_definition_clause` that specifies an attribute that denotes a subprogram, the profile shall be mode conformant with the one required for the attribute, and the convention shall be `Ada`. Additional requirements are defined for particular attributes. 6

Ramification: This implies, for example, that if one writes: 6.a

```
for T'Read use R; 6.b
```

`R` has to be a procedure with two parameters with the appropriate subtypes and modes as shown in 13.13.2. 6.c

- 7/2 {AI95-00270-01} A *Size clause* is an `attribute_definition_clause` whose `attribute_designator` is `Size`. Similar definitions apply to the other specifiable attributes.
- 7.a **To be honest:** An `attribute_definition_clause` is type-related or subtype-specific if the `attribute_designator` denotes a type-related or subtype-specific attribute, respectively.
- 8 A *storage element* is an addressable element of storage in the machine. A *word* is the largest amount of storage that can be conveniently and efficiently manipulated by the hardware, given the implementation's run-time model. A word consists of an integral number of storage elements.
- 8.a **Discussion:** A storage element is not intended to be a single bit, unless the machine can efficiently address individual bits.
- 8.b **Ramification:** For example, on a machine with 8-bit storage elements, if there exist 32-bit integer registers, with a full set of arithmetic and logical instructions to manipulate those registers, a word ought to be 4 storage elements — that is, 32 bits.
- 8.c **Discussion:** The “given the implementation's run-time model” part is intended to imply that, for example, on an 80386 running MS-DOS, the word might be 16 bits, even though the hardware can support 32 bits.
- 8.d A word is what ACID refers to as a “natural hardware boundary”.
- 8.e Storage elements may, but need not be, independently addressable (see 9.10, “Shared Variables”). Words are expected to be independently addressable.
- 8.1/3 {AI95-00133-01} {AI05-0092-1} A *machine scalar* is an amount of storage that can be conveniently and efficiently loaded, stored, or operated upon by the hardware. Machine scalars consist of an integral number of storage elements. The set of machine scalars is implementation defined, but includes at least the storage element and the word. Machine scalars are used to interpret `component_clauses` when the nondefault bit ordering applies.
- 8.e.1/2 **Implementation defined:** The set of machine scalars.
- 8.f/3 **Ramification:** {AI05-0092-1} A single storage element is a machine scalar in all Ada implementations. Similarly, a word is a machine scalar in all implementations (although it might be the same as a storage element). An implementation may define other machine scalars that make sense on the target (a half-word, for instance).
- 9/3 {8652/0009} {AI95-00137-01} {AI05-0191-1} The following representation attributes are defined: `Address`, `Alignment`, `Size`, `Storage_Size`, `Component_Size`, `Has_Same_Storage`, and `Overlaps_Storage`.
- 10/1 For a prefix `X` that denotes an object, program unit, or label:
- 11 `X'Address` Denotes the address of the first of the storage elements allocated to `X`. For a program unit or label, this value refers to the machine code associated with the corresponding body or **statement**. The value of this attribute is of type `System.Address`.
- 11.a **Ramification:** Here, the “first of the storage elements” is intended to mean the one with the lowest address; the endianness of the machine doesn't matter.
- 11.1/3 {AI05-0095-1} The prefix of `X'Address` shall not statically denote a subprogram that has convention `Intrinsic`. `X'Address` raises `Program_Error` if `X` denotes a subprogram that has convention `Intrinsic`.
- 12 Address may be specified for stand-alone objects and for program units via an `attribute_definition_clause`.
- 12.a **Ramification:** Address is not allowed for enumeration literals, predefined operators, derived task types, or derived protected types, since they are not program units.
- 12.b/3 Address is not allowed for intrinsic subprograms, either. That can be checked statically unless the prefix is a generic formal subprogram and the attribute reference is in the body of a generic unit. We define that case to raise `Program_Error`, in order that the compiler does not have to build a wrapper for intrinsic subprograms.
- 12.c The validity of a given address depends on the run-time model; thus, in order to use `Address` clauses correctly, one needs intimate knowledge of the run-time model.

{AI05-0229-1} If the Address of an object is specified, any explicit or implicit initialization takes place as usual, unless the Import aspect is also specified for the object (in which case any necessary initialization is presumably done in the foreign language).	12.d/3
Any compilation unit containing an <code>attribute_reference</code> of a given type depends semantically on the declaration of the package in which the type is declared, even if not mentioned in an applicable <code>with_clause</code> — see 10.1.1. In this case, it means that if a compilation unit contains <code>X'Address</code> , then it depends on the declaration of <code>System</code> . Otherwise, the fact that the value of <code>Address</code> is of a type in <code>System</code> wouldn't make sense; it would violate the “legality determinable via semantic dependences” Language Design Principle.	12.e
AI83-00305 — If <code>X</code> is a task type, then within the body of <code>X</code> , <code>X</code> denotes the current task object; thus, <code>X'Address</code> denotes the object's address.	12.f
Interrupt entries and their addresses are described in J.7.1, “Interrupt Entries”.	12.g
If <code>X</code> is not allocated on a storage element boundary, <code>X'Address</code> points at the first of the storage elements that contains any part of <code>X</code> . This is important for the definition of the <code>Position</code> attribute to be sensible.	12.h
Aspect Description for Address: Machine address of an entity.	12.i/3
<i>Erroneous Execution</i>	
{AI05-0009-1} If an <code>Address</code> is specified, it is the programmer's responsibility to ensure that the address is valid and appropriate for the entity and its use; otherwise, program execution is erroneous.	13/3
Discussion: “Appropriate for the entity and its use” covers cases such as misaligned addresses, read-only code addresses for variable data objects (and nonexecutable data addresses for code units), and addresses which would force objects that are supposed to be independently addressable to not be. Such addresses may be “valid” as they designate locations that are accessible to the program, but the program execution is still erroneous (meaning that implementations do not have to worry about these cases).	13.a
<i>Implementation Advice</i>	
For an array <code>X</code> , <code>X'Address</code> should point at the first component of the array, and not at the array bounds.	14
Implementation Advice: For an array <code>X</code> , <code>X'Address</code> should point at the first component of the array rather than the array bounds.	14.a.1/2
Ramification: On the other hand, we have no advice to offer about discriminants and tag fields; whether or not the address points at them is not specified by the language. If discriminants are stored separately, then the <code>Position</code> of a discriminant might be negative, or might raise an exception.	14.a
The recommended level of support for the <code>Address</code> attribute is:	15
<ul style="list-style-type: none"> • <code>X'Address</code> should produce a useful result if <code>X</code> is an object that is aliased or of a by-reference type, or is an entity whose <code>Address</code> has been specified. 	16
Reason: Aliased objects are the ones for which the <code>Unchecked_Access</code> attribute is allowed; hence, these have to be allocated on an addressable boundary anyway. Similar considerations apply to objects of a by-reference type.	16.a
An implementation need not go to any trouble to make <code>Address</code> work in other cases. For example, if an object <code>X</code> is not aliased and not of a by-reference type, and the implementation chooses to store it in a register, <code>X'Address</code> might return <code>System.Null_Address</code> (assuming registers are not addressable). For a subprogram whose calling convention is <code>Intrinsic</code> , or for a package, the implementation need not generate an out-of-line piece of code for it.	16.b
<ul style="list-style-type: none"> • An implementation should support <code>Address</code> clauses for imported subprograms. 	17
<ul style="list-style-type: none"> • <i>This paragraph was deleted.</i> {AI95-00291-02} 	18/2
<i>This paragraph was deleted.</i>	18.a/2
<ul style="list-style-type: none"> • If the <code>Address</code> of an object is specified, or it is imported or exported, then the implementation should not perform optimizations based on assumptions of no aliases. 	19
Implementation Advice: The recommended level of support for the <code>Address</code> attribute should be followed.	19.a/2
NOTES	
2 The specification of a link name with the <code>Link_Name</code> aspect (see B.1) for a subprogram or object is an alternative to explicit specification of its link-time address, allowing a link-time directive to place the subprogram or object within memory.	20

- 21 3 The rules for the Size attribute imply, for an aliased object X, that if X'Size = Storage_Unit, then X'Address points at a storage element containing all of the bits of X, and only the bits of X.

Wording Changes from Ada 83

- 21.a The intended meaning of the various attributes, and their `attribute_definition_clauses`, is more explicit.
- 21.b The `address_clause` has been renamed to `at_clause` and moved to Annex J, “Obsolescent Features”. One can use an Address clause (“for T'Address **use** ...;”) instead.
- 21.c The attributes defined in RM83-13.7.3 are moved to Annex G, A.5.3, and A.5.4.

Wording Changes from Ada 2005

- 21.c.1/3 {AI05-0183-1} Defined that the names of aspects are the same as the name of the attribute; that gives a name to use in `aspect_specifications` (see 13.1.1).

Language Design Principles

- 21.d By default, the Alignment of a subtype should reflect the “natural” alignment for objects of the subtype on the machine. The Alignment, whether specified or default, should be known at compile time, even though Addresses are generally not known at compile time. (The generated code should never need to check at run time the number of zero bits at the end of an address to determine an alignment).
- 21.e There are two symmetric purposes of Alignment clauses, depending on whether or not the implementation has control over object allocation. If the implementation allocates an object, the implementation should ensure that the Address and Alignment are consistent with each other. If something outside the implementation allocates an object, the implementation should be allowed to assume that the Address and Alignment are consistent, but should not assume stricter alignments than that.

Static Semantics

- 22/2 {AI95-00291-02} For a prefix X that denotes an object:

23/2 X'Alignment

{AI95-00291-02} The value of this attribute is of type *universal_integer*, and nonnegative; zero means that the object is not necessarily aligned on a storage element boundary. If X'Alignment is not zero, then X is aligned on a storage unit boundary and X'Address is an integral multiple of X'Alignment (that is, the Address modulo the Alignment is zero).

24/2 *This paragraph was deleted.* {AI95-00291-02}

24.a **Ramification:** The Alignment is passed by an allocator to the Allocate operation; the implementation has to choose a value such that if the address returned by Allocate is aligned as requested, the generated code can correctly access the object.

24.b The above mention of “modulo” is referring to the “**mod**” operator declared in System.Storage_Elements; if $X \bmod N = 0$, then X is by definition aligned on an N-storage-element boundary.

25/2 {AI95-00291-02} Alignment may be specified for [stand-alone] objects via an `attribute_definition_clause`; the expression of such a clause shall be static, and its value nonnegative.

25.a/3 **Aspect Description for Alignment (object):** Alignment of an object.

26/2 *This paragraph was deleted.* {AI95-00247-01}

26.1/2 {AI95-00291-02} For every subtype S:

26.2/2 S'Alignment

{AI95-00291-02} The value of this attribute is of type *universal_integer*, and nonnegative.

26.3/2 {AI95-00051-02} {AI95-00291-02} For an object X of subtype S, if S'Alignment is not zero, then X'Alignment is a nonzero integral multiple of S'Alignment unless specified otherwise by a representation item.

26.4/2 {AI95-00291-02} Alignment may be specified for first subtypes via an `attribute_definition_clause`; the expression of such a clause shall be static, and its value nonnegative.

26.a/3 **Aspect Description for Alignment (subtype):** Alignment of a subtype.

Erroneous Execution

- Program execution is erroneous if an Address clause is given that conflicts with the Alignment. 27
- Ramification:** The user has to either give an Alignment clause also, or else know what Alignment the implementation will choose by default. 27.a
- {AI95-00051-02} {AI95-00291-02} For an object that is not allocated under control of the implementation, execution is erroneous if the object is not aligned according to its Alignment. 28/2

Implementation Advice

- {AI05-0116-1} For any tagged specific subtype *S*, *S'*Class'Alignment should equal *S'*Alignment. 28.1/3
- Reason:** A tagged object should never be less aligned than the alignment of the type of its view, so for a class-wide type *T*'Class, the alignment should be no greater than that of any type covered by *T*'Class. If the implementation only supports alignments that are required by the recommended level of support (and this is most likely), then the alignment of any covered type has to be the same or greater than that of *T* — which leaves the only reasonable value of *T*'Class'Alignment being *T*'Alignment. Thus we recommend this, but don't require it so that in the unlikely case that the implementation does support smaller alignments for covered types, it can select a smaller value for *T*'Class'Alignment. 28.a/3
- Implementation Advice:** For any tagged specific subtype *S*, *S'*Class'Alignment should equal *S'*Alignment. 28.a.1/3

The recommended level of support for the Alignment attribute for subtypes is: 29

- {AI95-00051-02} An implementation should support an Alignment clause for a discrete type, fixed point type, record type, or array type, specifying an Alignment value that is zero or a power of two, subject to the following: 30/2
- {AI95-00051-02} An implementation need not support an Alignment clause for a signed integer type specifying an Alignment greater than the largest Alignment value that is ever chosen by default by the implementation for any signed integer type. A corresponding limitation may be imposed for modular integer types, fixed point types, enumeration types, record types, and array types. 31/2
- {AI95-00051-02} An implementation need not support a nonconfirming Alignment clause which could enable the creation of an object of an elementary type which cannot be easily loaded and stored by available machine instructions. 32/2
- {AI95-00291-02} An implementation need not support an Alignment specified for a derived tagged type which is not a multiple of the Alignment of the parent type. An implementation need not support a nonconfirming Alignment specified for a derived untagged by-reference type. 32.1/2

Ramification: {AI95-00291-02} There is no recommendation to support any nonconfirming Alignment clauses for types not mentioned above. Remember that 13.1 requires support for confirming Alignment clauses for all types. 32.a/2

Implementation Note: {AI05-0116-1} An implementation that tries to support other alignments for derived tagged types will need to allow inherited subprograms to be passed objects that are less aligned than expected by the parent subprogram and type. This is unlikely to work if alignment has any effect on code selection. Similar issues arise for untagged derived types whose parameters are passed by reference. 32.b/3

The recommended level of support for the Alignment attribute for objects is: 33

- *This paragraph was deleted.* {AI95-00291-02} 34/2
- For stand-alone library-level objects of statically constrained subtypes, the implementation should support all Alignments supported by the target linker. For example, page alignment is likely to be supported for such objects, but not for subtypes. 35
- {AI95-00291-02} For other objects, an implementation should at least support the alignments supported for their subtype, subject to the following: 35.1/2
- {AI95-00291-02} An implementation need not support Alignments specified for objects of a by-reference type or for objects of types containing aliased subcomponents if the specified Alignment is not a multiple of the Alignment of the subtype of the object. 35.2/2

Implementation Advice: The recommended level of support for the Alignment attribute should be followed. 35.a/2

NOTES

- 36 4 Alignment is a subtype-specific attribute.
- 37/2 *This paragraph was deleted. {AI95-00247-01}*
- 37.a/2 *This paragraph was deleted.*
- 38/3 5 {AI05-0229-1} {AI05-0269-1} A component_clause, Component_Size clause, or specifying the Pack aspect as True can override a specified Alignment.
- 38.a **Discussion:** Most objects are allocated by the implementation; for these, the implementation obeys the Alignment. The implementation is of course allowed to make an object *more* aligned than its Alignment requires — an object whose Alignment is 4 might just happen to land at an address that's a multiple of 4096. For formal parameters, the implementation might want to force an Alignment stricter than the parameter's subtype. For example, on some systems, it is customary to always align parameters to 4 storage elements.
- 38.b Hence, one might initially assume that the implementation could evilly make all Alignments 1 by default, even though integers, say, are normally aligned on a 4-storage-element boundary. However, the implementation cannot get away with that — if the Alignment is 1, the generated code cannot assume an Alignment of 4, at least not for objects allocated outside the control of the implementation.
- 38.c Of course implementations can assume anything they can prove, but typically an implementation will be unable to prove much about the alignment of, say, an imported object. Furthermore, the information about where an address “came from” can be lost to the compiler due to separate compilation.
- 38.d/3 {AI95-00114-01} {AI05-0229-1} The Alignment of an object that is a component of a packed composite object will usually be 0, to indicate that the component is not necessarily aligned on a storage element boundary. For a subtype, an Alignment of 0 means that objects of the subtype are not normally aligned on a storage element boundary at all. For example, an implementation might choose to make Component Size be 1 for an array of Booleans, even when the Pack aspect has not been specified for the array. In this case, Boolean'Alignment would be 0. (In the presence of tasking, this would in general be feasible only on a machine that had atomic test-bit and set-bit instructions.)
- 38.e If the machine has no particular natural alignments, then all subtype Alignments will probably be 1 by default.
- 38.f Specifying an Alignment of 0 in an attribute_definition_clause does not require the implementation to do anything (except return 0 when the Alignment is queried). However, it might be taken as advice on some implementations.
- 38.g It is an error for an Address clause to disobey the object's Alignment. The error cannot be detected at compile time, in general, because the Address is not necessarily known at compile time (and is almost certainly not static). We do not require a run-time check, since efficiency seems paramount here, and Address clauses are treading on thin ice anyway. Hence, this misuse of Address clauses is just like any other misuse of Address clauses — it's erroneous.
- 38.h A type extension can have a stricter Alignment than its parent. This can happen, for example, if the Alignment of the parent is 4, but the extension contains a component with Alignment 8. The Alignment of a class-wide type or object will have to be the maximum possible Alignment of any extension.
- 38.i The recommended level of support for the Alignment attribute is intended to reflect a minimum useful set of capabilities. An implementation can assume that all Alignments are multiples of each other — 1, 2, 4, and 8 might be the only supported Alignments for subtypes. An Alignment of 3 or 6 is unlikely to be useful. For objects that can be allocated statically, we recommend that the implementation support larger alignments, such as 4096. We do not recommend such large alignments for subtypes, because the maximum subtype alignment will also have to be used as the alignment of stack frames, heap objects, and class-wide objects. Similarly, we do not recommend such large alignments for stack-allocated objects.
- 38.j If the maximum default Alignment is 8 (say, Long_Float'Alignment = 8), then the implementation can refuse to accept stricter alignments for subtypes. This simplifies the generated code, since the compiler can align the stack and class-wide types to this maximum without a substantial waste of space (or time).
- 38.k Note that the recommended level of support takes into account interactions between Size and Alignment. For example, on a 32-bit machine with 8-bit storage elements, where load and store instructions have to be aligned according to the size of the thing being loaded or stored, the implementation might accept an Alignment of 1 if the Size is 8, but might reject an Alignment of 1 if the Size is 32. On a machine where unaligned loads and stores are merely inefficient (as opposed to causing hardware traps), we would expect an Alignment of 1 to be supported for any Size.

Wording Changes from Ada 83

- 38.l The nonnegative part is missing from RM83 (for mod_clauses, see alignment_clauses, which are an obsolete version of Alignment clauses).

Static Semantics

- 39/1 For a prefix X that denotes an object:

X'Size	Denotes the size in bits of the representation of the object. The value of this attribute is of the type <i>universal_integer</i> .	40
	Ramification: Note that Size is in bits even if Machine_Radix is 10. Each decimal digit (and the sign) is presumably represented as some number of bits.	40.a
	Size may be specified for [stand-alone] objects via an <code>attribute_definition_clause</code> ; the expression of such a clause shall be static and its value nonnegative.	41
	Aspect Description for Size (object): Size in bits of an object.	41.a/3
	<i>Implementation Advice</i>	
	{AI95-00051-02} The size of an array object should not include its bounds.	41.1/2
	Implementation Advice: The Size of an array object should not include its bounds.	41.a.1/2
	{AI95-00051-02} {AI95-00291-02} The recommended level of support for the Size attribute of objects is the same as for subtypes (see below), except that only a confirming Size clause need be supported for an aliased elementary object.	42/2
	<ul style="list-style-type: none"> • <i>This paragraph was deleted.</i> {AI95-00051-02} 	43/2
	<i>Static Semantics</i>	
	For every subtype S:	44
S'Size	If S is definite, denotes the size [(in bits)] that the implementation would choose for the following objects of subtype S:	45
	<ul style="list-style-type: none"> • A record component of subtype S when the record type is packed. 	46
	<ul style="list-style-type: none"> • The formal parameter of an instance of <code>Unchecked_Conversion</code> that converts from subtype S to some other subtype. 	47
	If S is indefinite, the meaning is implementation defined. The value of this attribute is of the type <i>universal_integer</i> . The Size of an object is at least as large as that of its subtype, unless the object's Size is determined by a Size clause, a <code>component_clause</code> , or a <code>Component_Size</code> clause. Size may be specified for first subtypes via an <code>attribute_definition_clause</code> ; the expression of such a clause shall be static and its value nonnegative.	48
	Implementation defined: The meaning of Size for indefinite subtypes.	48.a
	Reason: The effects of specifying the Size of a subtype are:	48.b
	<ul style="list-style-type: none"> • <code>Unchecked_Conversion</code> works in a predictable manner. 	48.c
	<ul style="list-style-type: none"> • A composite type cannot be packed so tightly as to override the specified Size of a component's subtype. 	48.d
	<ul style="list-style-type: none"> • Assuming the Implementation Advice is obeyed, if the specified Size allows independent addressability, then the Size of certain objects of the subtype should be equal to the subtype's Size. This applies to stand-alone objects and to components (unless a <code>component_clause</code> or a <code>Component_Size</code> clause applies). 	48.e
	{AI05-0229-1} A <code>component_clause</code> or a <code>Component_Size</code> clause can cause an object to be smaller than its subtype's specified size. The aspect <code>Pack</code> cannot; if a component subtype's size is specified, this limits how tightly the composite object can be packed.	48.f/3
	The Size of a class-wide (tagged) subtype is unspecified, because it's not clear what it should mean; it should certainly not depend on all of the descendants that happen to exist in a given program. Note that this cannot be detected at compile time, because in a generic unit, it is not necessarily known whether a given subtype is class-wide. It might raise an exception on some implementations.	48.g
	Ramification: A Size clause for a numeric subtype need not affect the underlying numeric type. For example, if I say:	48.h
	<pre>type S is range 1..2; for S'Size use 64;</pre>	48.i
	I am not guaranteed that <code>S'Base'Last >= 2**63-1</code> , nor that intermediate results will be represented in 64 bits.	48.j
	Reason: There is no need to complicate implementations for this sort of thing, because the right way to affect the base range of a type is to use the normal way of declaring the base range:	48.k

48.l `type Big is range -2**63 .. 2**63 - 1;`
 `subtype Small is Big range 1..1000;`

48.m **Ramification:** The Size of a large unconstrained subtype (e.g. String'Size) is likely to raise Constraint_Error, since it is a nonstatic expression of type *universal_integer* that might overflow the largest signed integer type. There is no requirement that the largest integer type be able to represent the size in bits of the largest possible object.

48.n/3 **Aspect Description for Size (subtype):** Size in bits of a subtype.

Implementation Requirements

49 In an implementation, Boolean'Size shall be 1.

Implementation Advice

50/2 {AI95-00051-02} If the Size of a subtype allows for efficient independent addressability (see 9.10) on the target architecture, then the Size of the following objects of the subtype should equal the Size of the subtype:

- 51 • Aliased objects (including components).
- 52 • Unaliased components, unless the Size of the component is determined by a `component_clause` or `Component_Size` clause.

52.a.1/2 **Implementation Advice:** If the Size of a subtype allows for efficient independent addressability, then the Size of most objects of the subtype should equal the Size of the subtype.

52.a **Ramification:** Thus, on a typical 32-bit machine, “`for S'Size use 32;`” will guarantee that aliased objects of subtype S, and components whose subtype is S, will have Size = 32 (assuming the implementation chooses to obey this Implementation Advice). On the other hand, if one writes, “`for S2'Size use 5;`” then stand-alone objects of subtype S2 will typically have their Size rounded up to ensure independent addressability.

52.b Note that “`for S'Size use 32;`” does not cause things like formal parameters to have Size = 32 — the implementation is allowed to make all parameters be at least 64 bits, for example.

52.c Note that “`for S2'Size use 5;`” requires record components whose subtype is S2 to be exactly 5 bits if the record type is packed. The same is not true of array components; their Size may be rounded up to the nearest factor of the word size.

52.d/2 **Implementation Note:** {AI95-00291-02} On most machines, arrays don't contain gaps between elementary components; if the Component_Size is greater than the Size of the component subtype, the extra bits are generally considered part of each component, rather than gaps between components. On the other hand, a record might contain gaps between elementary components, depending on what sorts of loads, stores, and masking operations are generally done by the generated code.

52.e/2 {AI95-00291-02} For an array, any extra bits stored for each elementary component will generally be part of the component — the whole point of storing extra bits is to make loads and stores more efficient by avoiding the need to mask out extra bits. The PDP-10 is one counter-example; since the hardware supports byte strings with a gap at the end of each word, one would want to pack in that manner.

53 A Size clause on a composite subtype should not affect the internal layout of components.

53.a.1/2 **Implementation Advice:** A Size clause on a composite subtype should not affect the internal layout of components.

53.a/3 **Reason:** {AI05-0229-1} That's what Pack aspects, `record_representation_clauses`, and `Component_Size` clauses are for.

54 The recommended level of support for the Size attribute of subtypes is:

- 55 • The Size (if not specified) of a static discrete or fixed point subtype should be the number of bits needed to represent each value belonging to the subtype using an unbiased representation, leaving space for a sign bit only if the subtype contains negative values. If such a subtype is a first subtype, then an implementation should support a specified Size for it that reflects this representation.

55.a **Implementation Note:** This applies to static enumeration subtypes, using the internal codes used to represent the values.

55.b For a two's-complement machine, this implies that for a static signed integer subtype S, if all values of S are in the range $0 .. 2^n - 1$, or all values of S are in the range $-2^{n-1} .. 2^{n-1} - 1$, for some n less than or equal to the word size, then

S'Size should be \leq the smallest such n . For a one's-complement machine, it is the same except that in the second range, the lower bound “ -2^n ” is replaced by “ $-2^{n-1}+1$ ”.

If an integer subtype (whether signed or unsigned) contains no negative values, the Size should not include space for a sign bit. 55.c

Typically, the implementation will choose to make the Size of a subtype be exactly the smallest such n . However, it might, for example, choose a biased representation, in which case it could choose a smaller value. 55.d

{AI05-0229-1} On most machines, it is in general not a good idea to pack (parts of) multiple stand-alone objects into the same storage element, because (1) it usually doesn't save much space, and (2) it requires locking to prevent tasks from interfering with each other, since separate stand-alone objects are independently addressable. Therefore, if S'Size = 2 on a machine with 8-bit storage elements, the size of a stand-alone object of subtype S will probably not be 2. It might, for example, be 8, 16 or 32, depending on the availability and efficiency of various machine instructions. The same applies to components of composite types, unless Pack, Component_Size, or record layout is specified. 55.e/3

For an unconstrained discriminated object, if the implementation allocates the maximum possible size, then the Size attribute should return that maximum possible size. 55.f

Ramification: The Size of an object X is not usually the same as that of its subtype S. If X is a stand-alone object or a parameter, for example, most implementations will round X'Size up to a storage element boundary, or more, so X'Size might be greater than S'Size. On the other hand, X'Size cannot be less than S'Size, even if the implementation can prove, for example, that the range of values actually taken on by X during execution is smaller than the range of S. 55.g

For example, if S is a first integer subtype whose range is 0..3, S'Size will be probably be 2 bits, and components of packed composite types of this subtype will be 2 bits (assuming Storage_Unit is a multiple of 2), but stand-alone objects and parameters will probably not have a size of 2 bits; they might be rounded up to 32 bits, for example. On the other hand, Unchecked_Conversion will use the 2-bit size, even when converting a stand-alone object, as one would expect. 55.h

Another reason for making the Size of an object bigger than its subtype's Size is to support the run-time detection of uninitialized variables. The implementation might add an extra value to a discrete subtype that represents the uninitialized state, and check for this value on use. In some cases, the extra value will require an extra bit in the representation of the object. Such detection is not required by the language. If it is provided, the implementation has to be able to turn it off. For example, if the programmer gives a record_representation_clause or Component_Size clause that makes a component too small to allow the extra bit, then the implementation will not be able to perform the checking (not using this method, anyway). 55.i

The fact that the size of an object is not necessarily the same as its subtype can be confusing: 55.j

```
type Device_Register is range 0..2**8 - 1;
for Device_Register'Size use 8; -- Confusing!
My_Device : Device_Register;
for My_Device'Address use To_Address(16#FF00#); 55.k
```

The programmer might think that My_Device'Size is 8, and that My_Device'Address points at an 8-bit location. However, this is not true. In Ada 83 (and in Ada 95), My_Device'Size might well be 32, and My_Device'Address might well point at the high-order 8 bits of the 32-bit object, which are always all zero bits. If My_Device'Address is passed to an assembly language subprogram, based on the programmer's assumption, the program will not work properly. 55.l

Reason: It is not reasonable to require that an implementation allocate exactly 8 bits to all objects of subtype Device_Register. For example, in many run-time models, stand-alone objects and parameters are always aligned to a word boundary. Such run-time models are generally based on hardware considerations that are beyond the control of the implementer. (It is reasonable to require that an implementation allocate exactly 8 bits to all components of subtype Device_Register, if packed.) 55.m

Ramification: The correct way to write the above code is like this: 55.n

```
type Device_Register is range 0..2**8 - 1;
My_Device : Device_Register;
for My_Device'Size use 8;
for My_Device'Address use To_Address(16#FF00#); 55.o
```

If the implementation cannot accept 8-bit stand-alone objects, then this will be illegal. However, on a machine where an 8-bit device register exists, the implementation will probably be able to accept 8-bit stand-alone objects. Therefore, My_Device'Size will be 8, and My_Device'Address will point at those 8 bits, as desired. 55.p

If an object of subtype Device_Register is passed to a foreign language subprogram, it will be passed according to that subprogram's conventions. Most foreign language implementations have similar run-time model restrictions. For example, when passing to a C function, where the argument is of the C type char* (that is, pointer to char), the C 55.q

compiler will generally expect a full word value, either on the stack, or in a register. It will *not* expect a single byte. Thus, Size clauses for subtypes really have nothing to do with passing parameters to foreign language subprograms.

- 56 • For a subtype implemented with levels of indirection, the Size should include the size of the pointers, but not the size of what they point at.
- 56.a **Ramification:** For example, if a task object is represented as a pointer to some information (including a task stack), then the size of the object should be the size of the pointer. The Storage_Size, on the other hand, should include the size of the stack.
- 56.1/2 • {AI95-00051-02} An implementation should support a Size clause for a discrete type, fixed point type, record type, or array type, subject to the following:
 - 56.2/2 • {AI95-00051-02} An implementation need not support a Size clause for a signed integer type specifying a Size greater than that of the largest signed integer type supported by the implementation in the absence of a size clause (that is, when the size is chosen by default). A corresponding limitation may be imposed for modular integer types, fixed point types, enumeration types, record types, and array types.
- 56.b/2 **Discussion:** {AI95-00051-02} Note that the “corresponding limitation” for a record or array type implies that an implementation may impose some reasonable maximum size for records and arrays (e.g. 2**32 bits), which is an upper bound (“capacity” limit) on the size, whether chosen by default or by being specified by the user. The largest size supported for records need not be the same as the largest size supported for arrays.
- 56.b.1/3 **Ramification:** {AI05-0155-1} Only Size clauses with a size greater than or equal to the Size that would be chosen by default may be safely presumed to be supported on nonstatic elementary subtypes. Implementations may choose to support smaller sizes, but only if the Size allows any value of the subtype to be represented, for any possible value of the bounds.
- 56.3/2 • {AI95-00291-02} A nonconfirming size clause for the first subtype of a derived untagged by-reference type need not be supported.
- 56.c/2 **Implementation Advice:** The recommended level of support for the Size attribute should be followed.
- 56.d/2 **Ramification:** {AI95-00291-02} There is no recommendation to support any nonconfirming Size clauses for types not mentioned above. Remember that 13.1 requires support for confirming Size clauses for all types.

NOTES

- 57 6 Size is a subtype-specific attribute.
- 58/3 7 {AI05-0229-1} A component_clause or Component_Size clause can override a specified Size. Aspect Pack cannot.

Inconsistencies With Ada 83

- 58.a.1/2 {AI95-00114-01} We specify the meaning of Size in much more detail than Ada 83. This is not technically an inconsistency, but it is in practice, as most Ada 83 compilers use a different definition for Size than is required here. This should have been documented more explicitly during the Ada 9X process.

Wording Changes from Ada 83

- 58.a The requirement for a nonnegative value in a Size clause was not in RM83, but it's hard to see how it would make sense. For uniformity, we forbid negative sizes, rather than letting implementations define their meaning.

Static Semantics

- 59/1 For a prefix T that denotes a task object [(after any implicit dereference)]:
- 60/3 T.Storage_Size
 - {AI05-0229-1} Denotes the number of storage elements reserved for the task. The value of this attribute is of the type *universal_integer*. The Storage_Size includes the size of the task's stack, if any. The language does not specify whether or not it includes other storage associated with the task (such as the “task control block” used by some implementations.) If the aspect Storage_Size is specified for the type of the object, the value of the Storage_Size attribute is at least the value determined by the aspect.
- 60.a **Ramification:** The value of this attribute is never negative, since it is impossible to “reserve” a negative number of storage elements.

- If the implementation chooses to allocate an initial amount of storage, and then increase this as needed, the `Storage_Size` cannot include the additional amounts (assuming the allocation of the additional amounts can raise `Storage_Error`); this is inherent in the meaning of “reserved.” 60.b
- The implementation is allowed to allocate different amounts of storage for different tasks of the same subtype. 60.c
- `Storage_Size` is also defined for access subtypes — see 13.11. 60.d
- {AI95-0229-1} [Aspect `Storage_Size` specifies the amount of storage to be reserved for the execution of a task.] 61/3

Paragraphs 62 through 65 were moved to Annex J, “Obsolescent Features”.

Static Semantics

- {AI05-0229-1} {AI05-0269-1} For a task type (including the anonymous type of a `single_task_declaration`), the following language-defined representation aspect may be specified: 65.1/3

`Storage_Size` 65.2/3

The `Storage_Size` aspect is an expression, which shall be of any integer type.

To be honest: This definition somewhat conflicts with the “automatic” one for the obsolescent attribute `Storage_Size` (which can be specified). The only difference is where the given expression is evaluated. We intend for the above definition to supersede that “automatic” definition for this attribute. 65.a/3

Ramification: Note that the value of the `Storage_Size` aspect is an expression; it is not the *value* of an expression. The expression is evaluated for each object of the type (see below). 65.b/3

Aspect Description for `Storage_Size` (task): Size in storage elements reserved for a task type or single task object. 65.c/3

Legality Rules

- {AI05-0229-1} The `Storage_Size` aspect shall not be specified for a task interface type. 65.3/3

Dynamic Semantics

- {AI05-0229-1} When a task object is created, the expression (if any) associated with the `Storage_Size` aspect of its type is evaluated; the `Storage_Size` attribute of the newly created task object is at least the value of the expression. 66/3

Ramification: The implementation is allowed to round up a specified `Storage_Size` amount. For example, if the implementation always allocates in chunks of 4096 bytes, the number 200 might be rounded up to 4096. Also, if the user specifies a negative number, the implementation has to normalize this to 0, or perhaps to a positive number. 66.a

{AI05-0229-1} If the `Storage_Size` aspect is not specified for the type of the task object, the value of the `Storage_Size` attribute is unspecified. 66.b/3

- At the point of task object creation, or upon task activation, `Storage_Error` is raised if there is insufficient free storage to accommodate the requested `Storage_Size`. 67

Static Semantics

- For a prefix `X` that denotes an array subtype or array object [(after any implicit dereference)]: 68/1

`X'Component_Size` 69

Denotes the size in bits of components of the type of `X`. The value of this attribute is of type *universal_integer*.

`Component_Size` may be specified for array types via an `attribute_definition_clause`; the expression of such a clause shall be static, and its value nonnegative. 70

Implementation Note: The intent is that the value of `X'Component_Size` is always nonnegative. If the array is stored “backwards” in memory (which might be caused by an implementation-defined pragma), `X'Component_Size` is still positive. 70.a

Ramification: For an array object `A`, `A'Component_Size = A(I)'Size` for any index `I`. 70.b

Aspect Description for `Component_Size`: Size in bits of a component of an array type. 70.c/3

Implementation Advice

- 71 The recommended level of support for the `Component_Size` attribute is:
- 72 • An implementation need not support specified `Component_Sizes` that are less than the `Size` of the component subtype.
 - 73/3 • *{AI05-0229-1}* An implementation should support specified `Component_Sizes` that are factors and multiples of the word size. For such `Component_Sizes`, the array should contain no gaps between components. For other `Component_Sizes` (if supported), the array should contain no gaps between components when `Pack` is also specified; the implementation should forbid this combination in cases where it cannot support a no-gaps representation.
- 73.a/3 **Ramification:** *{AI05-0229-1}* For example, if `Storage_Unit = 8`, and `Word_Size = 32`, then the user is allowed to specify a `Component_Size` of 1, 2, 4, 8, 16, and 32, with no gaps. In addition, $n*32$ is allowed for positive integers n , again with no gaps. If the implementation accepts `Component_Size = 3`, then it might allocate 10 components per word, with a 2-bit gap at the end of each word (unless `Pack` is also specified), or it might not have any internal gaps at all. (There can be gaps at either end of the array.)
- 73.b/2 **Implementation Advice:** The recommended level of support for the `Component_Size` attribute should be followed.

Static Semantics

- 73.1/3 *{AI05-0191-1}* For a prefix `X` that denotes an object:
- 73.2/3 `X'Has_Same_Storage`
{AI05-0191-1} `X'Has_Same_Storage` denotes a function with the following specification:
- 73.3/3

```
function X'Has_Same_Storage (Arg : any_type)
return Boolean
```
- 73.4/3 *{AI05-0191-1}* *{AI05-0264-1}* The actual parameter shall be a name that denotes an object. The object denoted by the actual parameter can be of any type. This function evaluates the names of the objects involved and returns `True` if the representation of the object denoted by the actual parameter occupies exactly the same bits as the representation of the object denoted by `X`; otherwise, it returns `False`.
- 73.c/3 **Discussion:** `Has_Same_Storage` means that, if the representation is contiguous, the objects sit at the same address and occupy the same length of memory.
- 73.5/3 *{AI05-0191-1}* For a prefix `X` that denotes an object:
- 73.6/3 `X'Overlaps_Storage`
{AI05-0191-1} `X'Overlaps_Storage` denotes a function with the following specification:
- 73.7/3

```
function X'Overlaps_Storage (Arg : any_type)
return Boolean
```
- 73.8/3 *{AI05-0191-1}* *{AI05-0264-1}* The actual parameter shall be a name that denotes an object. The object denoted by the actual parameter can be of any type. This function evaluates the names of the objects involved and returns `True` if the representation of the object denoted by the actual parameter shares at least one bit with the representation of the object denoted by `X`; otherwise, it returns `False`.
- NOTES
- 73.9/3 8 *{AI05-0191-1}* `X'Has_Same_Storage(Y)` implies `X'Overlaps_Storage(Y)`.
- 73.10/3 9 *{AI05-0191-1}* `X'Has_Same_Storage(Y)` and `X'Overlaps_Storage(Y)` are not considered to be reads of `X` and `Y`.

Static Semantics

- 73.11/3 *{8652/0009}* *{AI95-00137-01}* *{AI05-0183-1}* The following type-related operational attribute is defined: `External_Tag`.
- 74/1 *{8652/0009}* *{AI95-00137-01}* For every subtype `S` of a tagged type `T` (specific or class-wide):

S'External_Tag 75/3
 {8652/0040} {AI95-00108-01} {AI05-0092-1} S'External_Tag denotes an external string representation for S'Tag; it is of the predefined type String. External_Tag may be specified for a specific tagged type via an `attribute_definition_clause`; the expression of such a clause shall be static. The default external tag representation is implementation defined. See 13.13.2. The value of External_Tag is never inherited[; the default value is always used unless a new value is directly specified for a type].

Implementation defined: The default external representation for a type tag. 75.a

Aspect Description for External_Tag: Unique identifier for a tagged type in streams. 75.b/3

Dynamic Semantics

{AI05-0113-1} If a user-specified external tag S'External_Tag is the same as T'External_Tag for some other tagged type declared by a different declaration in the partition, Program_Error is raised by the elaboration of the `attribute_definition_clause`. 75.1/3

Ramification: This rule does not depend on the visibility of the other tagged type, but it does depend on the existence of the other tagged type. The other tagged type could have the default external tag or a user-specified external tag. 75.c/3

This rule allows the same declaration to be elaborated multiple times. In that case, different types could have the same external tag. If that happens, Internal_Tag would return some unspecified tag, and Descendant_Tag probably would return the intended tag (using the given ancestor to determine which type is intended). However, in some cases (such as multiple instantiations of a derived tagged type declared in a generic body), Tag_Error might be raised by Descendant_Tag if multiple types are identified. 75.d/3

Note that while there is a race condition inherent in this definition (which `attribute_definition_clause` raises Program_Error depends on the order of elaboration), it doesn't matter as a program with two such clauses is simply wrong. Two types that both come from the same declaration are allowed, as noted previously. 75.e/3

Implementation Requirements

In an implementation, the default external tag for each specific tagged type declared in a partition shall be distinct, so long as the type is declared outside an instance of a generic body. If the compilation unit in which a given tagged type is declared, and all compilation units on which it semantically depends, are the same in two different partitions, then the external tag for the type shall be the same in the two partitions. What it means for a compilation unit to be the same in two different partitions is implementation defined. At a minimum, if the compilation unit is not recompiled between building the two different partitions that include it, the compilation unit is considered the same in the two partitions. 76

Implementation defined: What determines whether a compilation unit is the same in two different partitions. 76.a

Reason: These requirements are important because external tags are used for input/output of class-wide types. These requirements ensure that what is written by one program can be read back by some other program so long as they share the same declaration for the type (and everything it depends on). 76.b

The user may specify the external tag if (s)he wishes its value to be stable even across changes to the compilation unit in which the type is declared (or changes in some unit on which it depends). 76.c

{AI95-00114-01} We use a String rather than a Stream_Element_Array to represent an external tag for portability. 76.d/2

Ramification: Note that the characters of an external tag need not all be graphic characters. In other words, the external tag can be a sequence of arbitrary 8-bit bytes. 76.e

Implementation Permissions

{AI05-0113-1} If a user-specified external tag S'External_Tag is the same as T'External_Tag for some other tagged type declared by a different declaration in the partition, the partition may be rejected. 76.1/3

Ramification: This is, in general, a post-compilation check. This permission is intended for implementations that do link-time construction of the external tag lookup table; implementations that dynamically construct the table will likely prefer to raise Program_Error upon elaboration of the problem construct. We don't want this check to require any implementation complexity, as it will be very rare that there would be a problem. 76.f/3

NOTES

- 77/2 10 {AI95-00270-01} The following language-defined attributes are specifiable, at least for some of the kinds of entities to which they apply: Address, Alignment, Bit_Order, Component_Size, External_Tag, Input, Machine_Radix, Output, Read, Size, Small, Storage_Pool, Storage_Size, Stream_Size, and Write.
- 78 11 It follows from the general rules in 13.1 that if one writes “**for X'Size use Y;**” then the X'Size attribute_reference will return Y (assuming the implementation allows the Size clause). The same is true for all of the specifiable attributes except Storage_Size.
- 78.a **Ramification:** An implementation may specify that an implementation-defined attribute is specifiable for certain entities. This follows from the fact that the semantics of implementation-defined attributes is implementation defined. An implementation is not allowed to make a language-defined attribute specifiable if it isn't.

Examples

79 *Examples of attribute definition clauses:*

```
80 Byte : constant := 8;
   Page : constant := 2**12;

81 type Medium is range 0 .. 65_000;
   for Medium'Size use 2*Byte;
   for Medium'Alignment use 2;
   Device_Register : Medium;
   for Device_Register'Size use Medium'Size;
   for Device_Register'Address use System.Storage_Elements.To_Address(16#FFFF_0020#);

82 type Short is delta 0.01 range -100.0 .. 100.0;
   for Short'Size use 15;

83 for Car_Name'Storage_Size use -- specify access type's storage pool size
   2000*((Car'Size/System.Storage_Unit) +1); -- approximately 2000 cars

84/2 {AI95-00441-01} function My_Input(Stream : not null access
Ada.Streams.Root_Stream_Type'Class)
   return T;
   for T'Input use My_Input; -- see 13.13.2
```

NOTES

- 85 12 *Notes on the examples:* In the Size clause for Short, fifteen bits is the minimum necessary, since the type definition requires Short'Small <= 2**(-7).

Extensions to Ada 83

- 85.a The syntax rule for length_clause is replaced with the new syntax rule for attribute_definition_clause, and it is modified to allow a name (as well as an expression).

Wording Changes from Ada 83

- 85.b The syntax rule for attribute_definition_clause now requires that the prefix of the attribute be a local_name; in Ada 83 this rule was stated in the text.
- 85.c/2 {AI95-00114-01} In Ada 83, the relationship between an aspect_clause specifying a certain aspect and an attribute that queried that aspect was unclear. In Ada 95, they are the same, except for certain explicit exceptions.

Wording Changes from Ada 95

- 85.d/2 {8652/0009} {AI95-00137-01} **Corrigendum:** Added wording to specify for each attribute whether it is an operational or representation attribute.
- 85.e/2 {8652/0040} {AI95-00108-01} **Corrigendum:** Added wording to specify that External_Tag is never inherited.
- 85.f/2 {AI95-00051-01} {AI95-00291-01} Adjusted the Recommended Level of Support for Alignment to eliminate nonsense requirements and to ensure that useful capabilities are required.
- 85.g/2 {AI95-00051-01} {AI95-00291-01} Adjusted the Recommended Level of Support for Size to eliminate nonsense requirements and to ensure that useful capabilities are required. Also eliminated any dependence on whether an aspect was specified (a confirming representation item should not affect the semantics).
- 85.h/2 {AI95-00133-01} Added the definition of machine scalar.
- 85.i/2 {AI95-00247-01} Removed the requirement that specified alignments for a composite type cannot override those for their components, because it was never intended to apply to components whose location was specified with a

representation item. Moreover, it causes a difference in legality when a confirming alignment is specified for one of the composite types.

{AI95-00291-02} Removed recommended level of support rules about types with by-reference and aliased parts, because there are now blanket rules covering all recommended level of support rules. 85.j/2

{AI95-00291-02} Split the definition of Alignment for subtypes and for objects. This simplified the wording and eliminated confusion about which rules applied to objects, which applied to subtypes, and which applied to both. 85.k/2

Inconsistencies With Ada 2005

{AI95-0095-1} **Correction:** An address attribute with a prefix of a generic formal subprogram whose actual parameter has convention `Intrinsic` now raises `Program_Error`. Since it is unlikely that such an attribute would have done anything useful (a subprogram with convention `Intrinsic` is not expected to have a normal subprogram body), it is highly unlikely that any existing programs would notice the difference, and any that do probably are buggy. 85.l/3

{AI95-0113-1} **Correction:** User-specified external tags that conflict with other external tags raise `Program_Error` (or are optionally illegal). This was legal and did not raise an exception in the past, although the effects were not defined. So while a program might depend on such behavior, the results were not portable (even to different versions of the same implementation). Such programs should be rare. 85.m/3

Incompatibilities With Ada 2005

{AI05-0095-1} **Correction:** An address attribute with a prefix of a subprogram with convention `Intrinsic` is now illegal. Such attributes are very unlikely to have provided a useful answer (the intended meaning of convention `Intrinsic` is that there is no actual subprogram body for the operation), so this is highly unlikely to affect any existing programs unless they have a hidden bug. 85.n/3

Extensions to Ada 2005

{AI05-0191-1} Attributes `Has_Same_Storage` and `Overlaps_Storage` are new. 85.o/3

{AI05-0229-1} Aspect `Storage_Size` is new; pragma `Storage_Size` is now obsolescent, joining attribute `Storage_Size` for task types. 85.p/3

Wording Changes from Ada 2005

{AI05-0009-1} **Correction:** Improved the description of erroneous execution for address clauses to make it clear that specifying an address inappropriate for the entity will lead to erroneous execution. 85.q/3

{AI05-0116-1} **Correction:** Added Implementation Advice for the alignment of class-wide types. 85.r/3

13.4 Enumeration Representation Clauses

[An `enumeration_representation_clause` specifies the internal codes for enumeration literals.] 1

Syntax

`enumeration_representation_clause ::=` 2

`for first_subtype_local_name use enumeration_aggregate;`

`enumeration_aggregate ::= array_aggregate` 3

Name Resolution Rules

The `enumeration_aggregate` shall be written as a one-dimensional `array_aggregate`, for which the index subtype is the unconstrained subtype of the enumeration type, and each component expression is expected to be of any integer type. 4

Ramification: The “full coverage rules” for aggregates applies. An **others** is not allowed — there is no applicable index constraint in this context. 4.a

Legality Rules

The `first_subtype_local_name` of an `enumeration_representation_clause` shall denote an enumeration subtype. 5

Ramification: As for all type-related representation items, the `local_name` is required to denote a first subtype. 5.a

6/2 {AI95-00287-01} Each component of the `array_aggregate` shall be given by an expression rather than a \diamond . The expressions given in the `array_aggregate` shall be static, and shall specify distinct integer codes for each value of the enumeration type; the associated integer codes shall satisfy the predefined ordering relation of the type.

6.a **Reason:** Each value of the enumeration type has to be given an internal code, even if the first subtype of the enumeration type is constrained to only a subrange (this is only possible if the enumeration type is a derived type). This “full coverage” requirement is important because one may refer to `Enum'Base'First` and `Enum'Base'Last`, which need to have defined representations.

Static Semantics

7 An `enumeration_representation_clause` specifies the *coding* aspect of representation. The coding consists of the *internal code* for each enumeration literal, that is, the integral value used internally to represent each literal.

7.a/3 **Aspect Description for Coding:** Internal representation of enumeration literals. Specified by an `enumeration_representation_clause`, not by an `aspect_specification`.

Implementation Requirements

8 For nonboolean enumeration types, if the coding is not specified for the type, then for each value of the type, the internal code shall be equal to its position number.

8.a **Reason:** This default representation is already used by all known Ada compilers for nonboolean enumeration types. Therefore, we make it a requirement so users can depend on it, rather than feeling obliged to supply for every enumeration type an enumeration representation clause that is equivalent to this default rule.

8.b **Discussion:** For boolean types, it is relatively common to use all ones for True, and all zeros for False, since some hardware supports that directly. Of course, for a one-bit Boolean object (like in a packed array), False is presumably zero and True is presumably one (choosing the reverse would be extremely unfriendly!).

Implementation Advice

9 The recommended level of support for `enumeration_representation_clauses` is:

- 10 • An implementation should support at least the internal codes in the range `System.Min_Int..System.Max_Int`. An implementation need not support `enumeration_representation_clauses` for boolean types.

10.a **Ramification:** The implementation may support numbers outside the above range, such as numbers greater than `System.Max_Int`. See AI83-00564.

10.b **Reason:** The benefits of specifying the internal coding of a boolean type do not outweigh the implementation costs. Consider, for example, the implementation of the logical operators on a packed array of booleans with strange internal codes. It's implementable, but not worth it.

10.c/2 **Implementation Advice:** The recommended level of support for `enumeration_representation_clauses` should be followed.

NOTES

11/3 13 {8652/0009} {AI95-00137-01} {AI05-0299-1} `Unchecked_Conversion` may be used to query the internal codes used for an enumeration type. The attributes of the type, such as `Succ`, `Pred`, and `Pos`, are unaffected by the `enumeration_representation_clause`. For example, `Pos` always returns the position number, *not* the internal integer code that might have been specified in an `enumeration_representation_clause`.

11.a **Discussion:** Suppose the enumeration type in question is derived:

```
11.b  type T1 is (Red, Green, Blue);
      subtype S1 is T1 range Red .. Green;
      type S2 is new S1;
      for S2 use (Red => 10, Green => 20, Blue => 30);
```

11.c/1 {8652/0009} {AI95-00137-01} The `enumeration_representation_clause` has to specify values for all enumerals, even ones that are not in S2 (such as Blue). The `Base` attribute can be used to get at these values. For example:

```
11.d  for I in S2'Base loop
      ... -- When I equals Blue, the internal code is 30.
    end loop;
```

We considered allowing or requiring “**for S2'Base use ...**” in cases like this, but it didn't seem worth the trouble. 11.e

Examples

Example of an enumeration representation clause: 12

```
type Mix_Code is (ADD, SUB, MUL, LDA, STA, STZ); 13
```

```
for Mix_Code use  
(ADD => 1, SUB => 2, MUL => 3, LDA => 8, STA => 24, STZ =>33); 14
```

Extensions to Ada 83

As in other similar contexts, Ada 95 allows expressions of any integer type, not just expressions of type *universal integer*, for the component expressions in the `enumeration_aggregate`. The preference rules for the predefined operators of *root_integer* eliminate any ambiguity. 14.a

For portability, we now require that the default coding for an enumeration type be the “obvious” coding using position numbers. This is satisfied by all known implementations. 14.b

Wording Changes from Ada 95

{8652/0009} {A195-00137-01} **Corrigendum:** Updated to reflect that we no longer have something called `representation_clause`. 14.c/2

{A195-00287-01} Added wording to prevent the use of `<>` in a `enumeration_representation_clause`. (`<>` is newly added to `array_aggregates`.) 14.d/2

13.5 Record Layout

The (*record*) *layout* aspect of representation consists of the *storage places* for some or all components, that is, storage place attributes of the components. The layout can be specified with a `record_representation_clause`. 1

13.5.1 Record Representation Clauses

[A `record_representation_clause` specifies the storage representation of records and record extensions, that is, the order, position, and size of components (including discriminants, if any).] 1

Language Design Principles

{A195-00114-01} It should be feasible for an implementation to use negative offsets in the representation of composite types. However, no implementation should be forced to support negative offsets. Therefore, in the interest of uniformity, negative offsets should be disallowed in `record_representation_clauses`. 1.a/2

Syntax

```
record_representation_clause ::= 2
```

```
  for first_subtype_local_name use  
  record [mod_clause]  
    {component_clause}  
  end record;
```

```
component_clause ::= 3  
  component_local_name at position range first_bit .. last_bit;
```

```
position ::= static_expression 4
```

```
first_bit ::= static_simple_expression 5
```

```
last_bit ::= static_simple_expression 6
```

Reason: *First_bit* and *last_bit* need to be `simple_expression` instead of `expression` for the same reason as in `range` (see 3.5, “Scalar Types”). 6.a

Name Resolution Rules

7 Each position, first_bit, and last_bit is expected to be of any integer type.

7.a **Ramification:** These need not have the same integer type.

Legality Rules

8/2 {AI95-00436-01} The *first_subtype_local_name* of a *record_representation_clause* shall denote a specific record or record extension subtype.

8.a **Ramification:** As for all type-related representation items, the *local_name* is required to denote a first subtype.

9 If the *component_local_name* is a *direct_name*, the *local_name* shall denote a component of the type. For a record extension, the component shall not be inherited, and shall not be a discriminant that corresponds to a discriminant of the parent type. If the *component_local_name* has an *attribute_designator*, the *direct_name* of the *local_name* shall denote either the declaration of the type or a component of the type, and the *attribute_designator* shall denote an implementation-defined implicit component of the type.

10 The position, first_bit, and last_bit shall be static expressions. The value of position and first_bit shall be nonnegative. The value of last_bit shall be no less than first_bit – 1.

10.a **Ramification:** A *component_clause* such as “X at 4 range 0..-1;” is allowed if X can fit in zero bits.

10.1/2 {AI95-00133-01} If the nondefault bit ordering applies to the type, then either:

- 10.2/2 • the value of last_bit shall be less than the size of the largest machine scalar; or
- 10.3/2 • the value of first_bit shall be zero and the value of last_bit + 1 shall be a multiple of System.Storage_Unit.

11 At most one *component_clause* is allowed for each component of the type, including for each discriminant (*component_clauses* may be given for some, all, or none of the components). Storage places within a *component_list* shall not overlap, unless they are for components in distinct variants of the same *variant_part*.

12 A name that denotes a component of a type is not allowed within a *record_representation_clause* for the type, except as the *component_local_name* of a *component_clause*.

12.a **Reason:** It might seem strange to make the *record_representation_clause* part of the declarative region, and then disallow mentions of the components within almost all of the *record_representation_clause*. The alternative would be to treat the *component_local_name* like a formal parameter name in a subprogram call (in terms of visibility). However, this rule would imply slightly different semantics, because (given the actual rule) the components can hide other declarations. This was the rule in Ada 83, and we see no reason to change it. The following, for example, was and is illegal:

```
12.b      type T is
          record
            X : Integer;
          end record;
          X : constant := 31; -- Same defining name as the component.
          for T use
            record
              X at 0 range 0..X; -- Illegal!
            end record;
```

12.c The component X hides the named number X throughout the *record_representation_clause*.

Static Semantics

13/2 {AI95-00133-01} A *record_representation_clause* (without the *mod_clause*) specifies the layout.

13.a/3 **Aspect Description for Layout (record):** Layout of record components. Specified by a *record_representation_clause*, not by an *aspect_specification*.

13.b/3 **Aspect Description for Record layout:** See Layout.

{AI95-00133-01} If the default bit ordering applies to the type, the `position`, `first_bit`, and `last_bit` of each `component_clause` directly specify the position and size of the corresponding component. 13.1/2

{AI95-00133-01} *{AI05-0264-1}* If the nondefault bit ordering applies to the type, then the layout is determined as follows: 13.2/3

- the `component_clauses` for which the value of `last_bit` is greater than or equal to the size of the largest machine scalar directly specify the position and size of the corresponding component; 13.3/2
- for other `component_clauses`, all of the components having the same value of `position` are considered to be part of a single machine scalar, located at that `position`; this machine scalar has a size which is the smallest machine scalar size larger than the largest `last_bit` for all `component_clauses` at that `position`; the `first_bit` and `last_bit` of each `component_clause` are then interpreted as bit offsets in this machine scalar. 13.4/2

This paragraph was deleted. {AI95-00133-01} 13.c/2

Ramification: A `component_clause` also determines the value of the `Size` attribute of the component, since this attribute is related to `First_Bit` and `Last_Bit`. 13.d

[A `record_representation_clause` for a record extension does not override the layout of the parent part;] if the layout was specified for the parent type, it is inherited by the record extension. 14

Implementation Permissions

An implementation may generate implementation-defined components (for example, one containing the offset of another component). An implementation may generate names that denote such implementation-defined components; such names shall be implementation-defined `attribute_references`. An implementation may allow such implementation-defined names to be used in `record_representation_clauses`. An implementation can restrict such `component_clauses` in any manner it sees fit. 15

Implementation defined: Implementation-defined components. 15.a

Ramification: Of course, since the semantics of implementation-defined attributes is implementation defined, the implementation need not support these names in all situations. They might be purely for the purpose of `component_clauses`, for example. The visibility rules for such names are up to the implementation. 15.b

We do not allow such component names to be normal identifiers — that would constitute blanket permission to do all kinds of evil things. 15.c

Discussion: Such implementation-defined components are known in the vernacular as “dope.” Their main purpose is for storing offsets of components that depend on discriminants. 15.d

If a `record_representation_clause` is given for an untagged derived type, the storage place attributes for all of the components of the derived type may differ from those of the corresponding components of the parent type, even for components whose storage place is not specified explicitly in the `record_representation_clause`. 16

Reason: This is clearly necessary, since the whole record may need to be laid out differently. 16.a

Implementation Advice

The recommended level of support for `record_representation_clauses` is: 17

- *{AI95-00133-01}* An implementation should support machine scalars that correspond to all of the integer, floating point, and address formats supported by the machine. 17.1/2
- An implementation should support storage places that can be extracted with a load, mask, shift sequence of machine code, and set with a load, shift, mask, store sequence, given the available machine instructions and run-time model. 18
- A storage place should be supported if its size is equal to the `Size` of the component subtype, and it starts and ends on a boundary that obeys the `Alignment` of the component subtype. 19

- 20/2 • *{AI95-00133-01}* For a component with a subtype whose Size is less than the word size, any storage place that does not cross an aligned word boundary should be supported.
- 20.a **Reason:** The above recommendations are sufficient to define interfaces to most interesting hardware. This causes less implementation burden than the definition in ACID, which requires arbitrary bit alignments of arbitrarily large components. Since the ACID definition is neither enforced by the ACVC, nor supported by all implementations, it seems OK for us to weaken it.
- 21 • An implementation may reserve a storage place for the tag field of a tagged type, and disallow other components from overlapping that place.
- 21.a **Ramification:** Similar permission for other dope is not granted.
- 22 • An implementation need not support a `component_clause` for a component of an extension part if the storage place is not after the storage places of all components of the parent type, whether or not those storage places had been specified.
- 22.a **Reason:** These restrictions are probably necessary if block equality operations are to be feasible for class-wide types. For block comparison to work, the implementation typically has to fill in any gaps with zero (or one) bits. If a “gap” in the parent type is filled in with a component in a type extension, then this won't work when a class-wide object is passed by reference, as is required.
- 22.b/2 **Implementation Advice:** The recommended level of support for `record_representation_clauses` should be followed.

NOTES

- 23 14 If no `component_clause` is given for a component, then the choice of the storage place for the component is left to the implementation. If `component_clauses` are given for all components, the `record_representation_clause` completely specifies the representation of the type and will be obeyed exactly by the implementation.
- 23.a **Ramification:** The visibility rules prevent the name of a component of the type from appearing in a `record_representation_clause` at any place *except* for the `component_local_name` of a `component_clause`. However, since the `record_representation_clause` is part of the declarative region of the type declaration, the component names hide outer homographs throughout.
- 23.b/1 *{8652/0009} {AI95-00137-01}* A `record_representation_clause` cannot be given for a protected type, even though protected types, like record types, have components. The primary reason for this rule is that there is likely to be too much dope in a protected type — entry queues, bit maps for barrier values, etc. In order to control the representation of the user-defined components, simply declare a record type, give it a `record_representation_clause`, and give the protected type one component whose type is the record type. Alternatively, if the protected object is protecting something like a device register, it makes more sense to keep the thing being protected outside the protected object (possibly with a pointer to it in the protected object), in order to keep implementation-defined components out of the way.

Examples

- 24 *Example of specifying the layout of a record type:*
- 25 `Word : constant := 4; -- storage element is byte, 4 bytes per word`
- 26 `type State is (A,M,W,P);`
`type Mode is (Fix, Dec, Exp, Signif);`
- 27 `type Byte_Mask is array (0..7) of Boolean;`
`type State_Mask is array (State) of Boolean;`
`type Mode_Mask is array (Mode) of Boolean;`
- 28 `type Program_Status_Word is`
`record`
`System_Mask : Byte_Mask;`
`Protection_Key : Integer range 0 .. 3;`
`Machine_State : State_Mask;`
`Interrupt_Cause : Interruption_Code;`
`Ilc : Integer range 0 .. 3;`
`Cc : Integer range 0 .. 3;`
`Program_Mask : Mode_Mask;`
`Inst_Address : Address;`
`end record;`

```

for Program_Status_Word use
  record
    System_Mask      at 0*Word range 0 .. 7;
    Protection_Key   at 0*Word range 10 .. 11; -- bits 8,9 unused
    Machine_State    at 0*Word range 12 .. 15;
    Interrupt_Cause  at 0*Word range 16 .. 31;
    Ilc              at 1*Word range 0 .. 1;  -- second word
    Cc               at 1*Word range 2 .. 3;
    Program_Mask     at 1*Word range 4 .. 7;
    Inst_Address     at 1*Word range 8 .. 31;
  end record;

for Program_Status_Word'Size use 8*System.Storage_Unit;
for Program_Status_Word'Alignment use 8;

```

NOTES

15 *Note on the example:* The `record_representation_clause` defines the record layout. The `Size` clause guarantees that (at least) eight storage elements are used for objects of the type. The `Alignment` clause guarantees that aliased, imported, or exported objects of the type will have addresses divisible by eight. 31

Wording Changes from Ada 83

The `alignment_clause` has been renamed to `mod_clause` and moved to Annex J, “Obsolescent Features”. 31.a

We have clarified that implementation-defined component names have to be in the form of an `attribute_reference` of a component or of the first subtype itself; surely Ada 83 did not intend to allow arbitrary identifiers. 31.b

The RM83-13.4(7) wording incorrectly allows components in nonvariant records to overlap. We have corrected that oversight. 31.c

Incompatibilities With Ada 95

{AI95-00133-01} **Amendment Correction:** The meaning of a `record_representation_clause` for the nondefault bit order is now clearly defined. Thus, such clauses can be portably written. In order to do that though, the equivalence of bit 1 in word 1 to bit 9 in word 0 (for a machine with `Storage_Unit = 8`) had to be dropped for the nondefault bit order. Any `record_representation_clauses` which depends on that equivalence will break (although such code would imply a noncontiguous representation for a component, and it seems unlikely that compilers were supporting that anyway). 31.d/2

Extensions to Ada 95

{AI95-00436-01} **Amendment Correction:** The undocumented (and likely unintentional) incompatibility with Ada 83 caused by not allowing `record_representation_clauses` on limited record types is removed. 31.e/2

13.5.2 Storage Place Attributes

Static Semantics

For a component `C` of a composite, non-array object `R`, the *storage place attributes* are defined: 1

Ramification: The storage place attributes are not (individually) specifiable, but the user may control their values by giving a `record_representation_clause`. 1.a

R.C'Position 2/2

{AI95-00133-01} If the nondefault bit ordering applies to the composite type, and if a `component_clause` specifies the placement of `C`, denotes the value given for the position of the `component_clause`; otherwise, denotes the same value as `R.C'Address - R'Address`. The value of this attribute is of the type *universal_integer*.

Ramification: {AI95-00133-01} Thus, for the default bit order, `R.C'Position` is the offset of `C` in storage elements from the beginning of the object, where the first storage element of an object is numbered zero. `R'Address + R.C'Position = R.C'Address`. For record extensions, the offset is not measured from the beginning of the extension part, but from the beginning of the whole object, as usual. 2.a/2

In “`R.C'Address - R'Address`”, the “`-`” operator is the one in `System.Storage_Elements` that takes two `Addresses` and returns a `Storage_Offset`. 2.b

- 3/2 R.C'First_Bit
 {AI95-00133-01} If the nondefault bit ordering applies to the composite type, and if a `component_clause` specifies the placement of C, denotes the value given for the `first_bit` of the `component_clause`; otherwise, denotes the offset, from the start of the first of the storage elements occupied by C, of the first bit occupied by C. This offset is measured in bits. The first bit of a storage element is numbered zero. The value of this attribute is of the type *universal_integer*.
- 4/2 R.C'Last_Bit
 {AI95-00133-01} If the nondefault bit ordering applies to the composite type, and if a `component_clause` specifies the placement of C, denotes the value given for the `last_bit` of the `component_clause`; otherwise, denotes the offset, from the start of the first of the storage elements occupied by C, of the last bit occupied by C. This offset is measured in bits. The value of this attribute is of the type *universal_integer*.
- 4.a/2 **Ramification:** {AI95-00114-01} The ordering of bits in a storage element is defined in 13.5.3, “Bit Ordering”.
- 4.b R.C'Size = R.C'Last_Bit – R.C'First_Bit + 1. (Unless the implementation chooses an indirection representation.)
- 4.c If a `component_clause` applies to a component, then that component will be at the same relative storage place in all objects of the type. Otherwise, there is no such requirement.

Implementation Advice

- 5 If a component is represented using some form of pointer (such as an offset) to the actual data of the component, and this data is contiguous with the rest of the object, then the storage place attributes should reflect the place of the actual data, not the pointer. If a component is allocated discontinuously from the rest of the object, then a warning should be generated upon reference to one of its storage place attributes.
- 5.a **Reason:** For discontinuous components, these attributes make no sense. For example, an implementation might allocate dynamic-sized components on the heap. For another example, an implementation might allocate the discriminants separately from the other components, so that multiple objects of the same subtype can share discriminants. Such representations cannot happen if there is a `component_clause` for that component.
- 5.b/2 **Implementation Advice:** If a component is represented using a pointer to the actual data of the component which is contiguous with the rest of the object, then the storage place attributes should reflect the place of the actual data. If a component is allocated discontinuously from the rest of the object, then a warning should be generated upon reference to one of its storage place attributes.

Incompatibilities With Ada 95

- 5.c/2 {AI95-00133-01} **Amendment Correction:** The meaning of the storage place attributes for the nondefault bit order is now clearly defined, and can be different than that given by strictly following the Ada 95 wording. Any code which depends on the original Ada 95 values for a type using the nondefault bit order where they are different will break.

13.5.3 Bit Ordering

- 1 [The `Bit_Order` attribute specifies the interpretation of the storage place attributes.]
- 1.a **Reason:** The intention is to provide uniformity in the interpretation of storage places across implementations on a particular machine by allowing the user to specify the `Bit_Order`. It is not intended to fully support data interoperability across different machines, although it can be used for that purpose in some situations.
- 1.b/2 {AI95-00114-01} We can't require all implementations on a given machine to use the same bit ordering by default; if the user cares, a `Bit_Order attribute_definition_clause` can be used to force all implementations to use the same bit ordering.

Static Semantics

- 2 A bit ordering is a method of interpreting the meaning of the storage place attributes. `High_Order_First` [(known in the vernacular as “big endian”)] means that the first bit of a storage element (bit 0) is the most significant bit (interpreting the sequence of bits that represent a component as an unsigned integer value).

Low_Order_First [(known in the vernacular as “little endian”)] means the opposite: the first bit is the least significant.

For every specific record subtype S, the following attribute is defined:

S'Bit_Order

Denotes the bit ordering for the type of S. The value of this attribute is of type System.Bit_Order. Bit_Order may be specified for specific record types via an attribute_definition_clause; the expression of such a clause shall be static.

Aspect Description for Bit_Order: Order of bit numbering in a record_representation_clause.

If Word_Size = Storage_Unit, the default bit ordering is implementation defined. If Word_Size > Storage_Unit, the default bit ordering is the same as the ordering of storage elements in a word, when interpreted as an integer.

Implementation defined: If Word_Size = Storage_Unit, the default bit ordering.

Ramification: Consider machines whose Word_Size = 32, and whose Storage_Unit = 8. Assume the default bit ordering applies. On a machine with big-endian addresses, the most significant storage element of an integer is at the address of the integer. Therefore, bit zero of a storage element is the most significant bit. On a machine with little-endian addresses, the least significant storage element of an integer is at the address of the integer. Therefore, bit zero of a storage element is the least significant bit.

The storage place attributes of a component of a type are interpreted according to the bit ordering of the type.

Ramification: This implies that the interpretation of the position, first_bit, and last_bit of a component_clause of a record_representation_clause obey the bit ordering given in a representation item.

Implementation Advice

The recommended level of support for the nondefault bit ordering is:

- {AI95-00133-01} The implementation should support the nondefault bit ordering in addition to the default bit ordering.

Ramification: {AI95-00133-01} The implementation should support both bit orderings. Implementations are required to support storage positions that cross storage element boundaries when Word_Size > Storage_Unit but the definition of the storage place attributes for the nondefault bit order ensures that such storage positions will not be split into two or three pieces. Thus, there is no significant implementation burden to supporting the nondefault bit order, given that the set of machine scalars is implementation-defined.

Implementation Advice: The recommended level of support for the nondefault bit ordering should be followed.

NOTES

16 {AI95-00133-01} Bit_Order clauses make it possible to write record_representation_clauses that can be ported between machines having different bit ordering. They do not guarantee transparent exchange of data between such machines.

Extensions to Ada 83

The Bit_Order attribute is new to Ada 95.

Wording Changes from Ada 95

{AI95-00133-01} We now suggest that all implementations support the nondefault bit order.

13.6 Change of Representation

{AI05-0229-1} [A type_conversion (see 4.6) can be used to convert between two different representations of the same array or record. To convert an array from one representation to another, two array types need to be declared with matching component subtypes, and convertible index types. If one type has Pack specified and the other does not, then explicit conversion can be used to pack or unpack an array.

2 To convert a record from one representation to another, two record types with a common ancestor type need to be declared, with no inherited subprograms. Distinct representations can then be specified for the record types, and explicit conversion between the types can be used to effect a change in representation.]

2.a **Ramification:** This technique does not work if the first type is an untagged type with user-defined primitive subprograms. It does not work at all for tagged types.

Examples

3 *Example of change of representation:*

```

4  -- Packed_Descriptor and Descriptor are two different types
5  -- with identical characteristics, apart from their
6  -- representation
7  type Descriptor is
8     record
9         -- components of a descriptor
10    end record;
11
12 type Packed_Descriptor is new Descriptor;
13
14 for Packed_Descriptor use
15     record
16         -- component clauses for some or for all components
17     end record;
18
19 -- Change of representation can now be accomplished by explicit type conversions:
20
21 D : Descriptor;
22 P : Packed_Descriptor;
23
24 P := Packed_Descriptor(D); -- pack D
25 D := Descriptor(P);       -- unpack P

```

13.7 The Package System

1 [For each implementation there is a library package called System which includes the definitions of certain configuration-dependent characteristics.]

Static Semantics

2 The following language-defined library package exists:

2.a/2 **Implementation defined:** The contents of the visible part of package System.

```

3/2 {AI95-00362-01} package System is
4     pragma Pure(System);
5
6     type Name is implementation-defined-enumeration-type;
7     System_Name : constant Name := implementation-defined;
8     -- System-Dependent Named Numbers:
9
10    Min_Int           : constant := root_integer'First;
11    Max_Int           : constant := root_integer'Last;
12
13    Max_Binary_Modulus : constant := implementation-defined;
14    Max_Nonbinary_Modulus : constant := implementation-defined;
15
16    Max_Base_Digits   : constant := root_real'Digits;
17    Max_Digits        : constant := implementation-defined;
18
19    Max_Mantissa       : constant := implementation-defined;
20    Fine_Delta         : constant := implementation-defined;
21
22    Tick               : constant := implementation-defined;
23
24    -- Storage-related Declarations:
25
26    type Address is implementation-defined;
27    Null_Address : constant Address;

```

```

Storage_Unit : constant := implementation-defined;
Word_Size   : constant := implementation-defined * Storage_Unit;
Memory_Size : constant := implementation-defined;
13

{AI05-0229-1} -- Address Comparison:
function "<" (Left, Right : Address) return Boolean
with Convention => Intrinsic;
function "<=" (Left, Right : Address) return Boolean
with Convention => Intrinsic;
function ">" (Left, Right : Address) return Boolean
with Convention => Intrinsic;
function ">=" (Left, Right : Address) return Boolean
with Convention => Intrinsic;
function "=" (Left, Right : Address) return Boolean
with Convention => Intrinsic;
-- function "/=" (Left, Right : Address) return Boolean;
-- "/=" is implicitly defined
14/3

{AI95-00221-01} -- Other System-Dependent Declarations:
type Bit_Order is (High_Order_First, Low_Order_First);
Default_Bit_Order : constant Bit_Order := implementation-defined;
15/2

-- Priority-related declarations (see D.1):
subtype Any_Priority is Integer range implementation-defined;
subtype Priority is Any_Priority range Any_Priority'First ..
implementation-defined;
16
subtype Interrupt_Priority is Any_Priority range Priority'Last+1 ..
Any_Priority'Last;

Default_Priority : constant Priority :=
(Priority'First + Priority'Last)/2;
17

private
... -- not specified by the language
end System;
18

```

Name is an enumeration subtype. Values of type Name are the names of alternative machine configurations handled by the implementation. System_Name represents the current machine configuration. 19

The named numbers Fine_Delta and Tick are of the type *universal_real*; the others are of the type *universal_integer*. 20

The meanings of the named numbers are: 21

[Min_Int The smallest (most negative) value allowed for the expressions of a *signed_integer_type_definition*. 22

Max_Int The largest (most positive) value allowed for the expressions of a *signed_integer_type_definition*. 23

Max_Binary_Modulus
A power of two such that it, and all lesser positive powers of two, are allowed as the modulus of a *modular_type_definition*. 24

Max_Nonbinary_Modulus
A value such that it, and all lesser positive integers, are allowed as the modulus of a *modular_type_definition*. 25

Ramification: There is no requirement that Max_Nonbinary_Modulus be less than or equal to Max_Binary_Modulus, although that's what makes most sense. On a typical 32-bit machine, for example, Max_Binary_Modulus will be 2**32 and Max_Nonbinary_Modulus will be 2**31, because supporting nonbinary moduli in above 2**31 causes implementation difficulties. 25.a

Max_Base_Digits
The largest value allowed for the requested decimal precision in a *floating_point_definition*. 26

Max_Digits
The largest value allowed for the requested decimal precision in a *floating_point_definition* that has no *real_range_specification*. Max_Digits is less than or equal to Max_Base_Digits. 27

- 28 **Max_Mantissa**
The largest possible number of binary digits in the mantissa of machine numbers of a user-defined ordinary fixed point type. (The mantissa is defined in Annex G.)
- 29 **Fine_Delta**
The smallest delta allowed in an `ordinary_fixed_point_definition` that has the `real_range_-specification` **range** `-1.0 .. 1.0`.]
- 30 **Tick**
A period in seconds approximating the real time interval during which the value of `Calendar.Clock` remains constant.
- 30.a **Ramification:** There is no required relationship between `System.Tick` and `Duration'Small`, other than the one described here.
- 30.b The inaccuracy of the `delay_statement` has no relation to `Tick`. In particular, it is possible that the clock used for the `delay_statement` is less accurate than `Calendar.Clock`.
- 30.c We considered making `Tick` a run-time-determined quantity, to allow for easier configurability. However, this would not be upward compatible, and the desired configurability can be achieved using functionality defined in Annex D, “Real-Time Systems”.
- 31 **Storage_Unit**
The number of bits per storage element.
- 32 **Word_Size**
The number of bits per word.
- 33 **Memory_Size**
An implementation-defined value [that is intended to reflect the memory size of the configuration in storage elements.]
- 33.a **Discussion:** It is unspecified whether this refers to the size of the address space, the amount of physical memory on the machine, or perhaps some other interpretation of “memory size.” In any case, the value has to be given by a static expression, even though the amount of memory on many modern machines is a dynamic quantity in several ways. Thus, `Memory_Size` is not very useful.
- 34/2 **{AI95-00161-01}** `Address` is a definite, nonlimited type with prelaborable initialization (see 10.2.1). `Address` represents machine addresses capable of addressing individual storage elements. `Null_Address` is an address that is distinct from the address of any object or program unit.
- 34.a **Ramification:** The implementation has to ensure that there is at least one address that nothing will be allocated to; `Null_Address` will be one such address.
- 34.b **Ramification:** `Address` is the type of the result of the attribute `Address`.
- 34.c **Reason:** `Address` is required to be nonlimited and definite because it is important to be able to assign addresses, and to declare uninitialized address variables.
- 34.d/2 **Ramification:** **{AI95-00161-01}** If `System.Address` is defined as a private type (as suggested below), it might be necessary to add a pragma `Prelaborable_Initialization` to the specification of `System` in order that `Address` have prelaborable initialization as required.
- 35/2 **{AI95-00221-01}** `Default_Bit_Order` shall be a static constant. See 13.5.3 for an explanation of `Bit_Order` and `Default_Bit_Order`.
- Implementation Permissions*
- 36/2 **{AI95-00362-01}** An implementation may add additional implementation-defined declarations to package `System` and its children. [However, it is usually better for the implementation to provide additional functionality via implementation-defined children of `System`.]
- 36.a **Ramification:** The declarations in package `System` and its children can be implicit. For example, since `Address` is not limited, the predefined `"=`" and `"/="` operations are probably sufficient. However, the implementation is not *required* to use the predefined `"=`".

Implementation Advice

- Address should be a private type. 37
- Reason:** This promotes uniformity by avoiding having implementation-defined predefined operations for the type. We don't require it, because implementations may want to stick with what they have. 37.a
- Implementation Advice:** Type System.Address should be a private type. 37.a.1/2
- Implementation Note:** It is not necessary for Address to be able to point at individual bits within a storage element. Nor is it necessary for it to be able to point at machine registers. It is intended as a memory address that matches the hardware's notion of an address. 37.b
- The representation of the **null** value of a general access type should be the same as that of Null_Address; instantiations of Unchecked_Conversion should work accordingly. If the implementation supports interfaces to other languages, the representation of the **null** value of a general access type should be the same as in those other languages, if appropriate. 37.c
- Note that the children of the Interfaces package will generally provide foreign-language-specific null values where appropriate. See UI-0065 regarding Null_Address. 37.d

NOTES

- 17 There are also some language-defined child packages of System defined elsewhere. 38

Extensions to Ada 83

- The declarations Max_Binary_Modulus, Max_Nonbinary_Modulus, Max_Base_Digits, Null_Address, Word_Size, Bit_Order, Default_Bit_Order, Any_Priority, Interrupt_Priority, and Default_Priority are added to System in Ada 95. The presence of ordering operators for type Address is also guaranteed (the existence of these depends on the definition of Address in an Ada 83 implementation). We do not list these as incompatibilities, as the contents of System can vary between implementations anyway; thus a program that depends on the contents of System (by using **use System**; for example) is already at risk of being incompatible when moved between Ada implementations. 38.a.1/1

Wording Changes from Ada 83

- Much of the content of System is standardized, to provide more uniformity across implementations. Implementations can still add their own declarations to System, but are encouraged to do so via children of System. 38.a
- Some of the named numbers are defined more explicitly in terms of the standard numeric types. 38.b
- The pragmas System_Name, Storage_Unit, and Memory_Size are no longer defined by the language. However, the corresponding declarations in package System still exist. Existing implementations may continue to support the three pragmas as implementation-defined pragmas, if they so desire. 38.c
- Priority semantics, including subtype Priority, have been moved to the Real Time Annex. 38.d

Extensions to Ada 95

- {AI95-00161-01} **Amendment Correction:** Type Address is defined to have preelaborable initialization, so that it can be used without restriction in preelaborated units. (If Address is defined to be a private type, as suggested by the Implementation Advice, in Ada 95 it cannot be used in some contexts in a preelaborated units. This is an unnecessary portability issue.) 38.e/2
- {AI95-00221-01} **Amendment Correction:** Default_Bit_Order is now a static constant. 38.f/2
- {AI95-00362-01} Package System is now Pure, so it can be portably used in more places. (Ada 95 allowed it to be Pure, but did not require that.) 38.g/2

13.7.1 The Package System.Storage_Elements*Static Semantics*

- The following language-defined library package exists: 1
- ```
{AI95-00362-01} package System.Storage_Elements is 2/2
 pragma Pure (Storage_Elements);
 type Storage_Offset is range implementation-defined; 3
 subtype Storage_Count is Storage_Offset range 0..Storage_Offset'Last; 4
```

```

5 type Storage_Element is mod implementation-defined;
 for Storage_Element'Size use Storage_Unit;
 type Storage_Array is array
 (Storage_Offset range <>) of aliased Storage_Element;
 for Storage_Array'Component_Size use Storage_Unit;
6 -- Address Arithmetic:
7/3 {AI05-0229-1} function "+"(Left : Address; Right : Storage_Offset) return
Address
 with Convention => Intrinsic;
 function "+"(Left : Storage_Offset; Right : Address) return Address
 with Convention => Intrinsic;
 function "-"(Left : Address; Right : Storage_Offset) return Address
 with Convention => Intrinsic;
 function "-"(Left, Right : Address) return Storage_Offset
 with Convention => Intrinsic;
8/3 {AI05-0229-1} function "mod"(Left : Address; Right : Storage_Offset)
return Storage_Offset
 with Convention => Intrinsic;
9 -- Conversion to/from integers:
10/3 {AI05-0229-1} type Integer_Address is implementation-defined;
 function To_Address(Value : Integer_Address) return Address
 with Convention => Intrinsic;
 function To_Integer(Value : Address) return Integer_Address
 with Convention => Intrinsic;
11/3 {AI05-0229-1} end System.Storage_Elements;
11.a/3 Reason: {AI05-0229-1} The Convention aspects imply that the attribute Access is not allowed for those operations.
11.b The mod function is needed so that the definition of Alignment makes sense.
11.c/2 Implementation defined: The range of Storage_Elements.Storage_Offset, the modulus of
Storage_Elements.Storage_Element, and the declaration of Storage_Elements.Integer_Address..
12 Storage_Element represents a storage element. Storage_Offset represents an offset in storage elements.
Storage_Count represents a number of storage elements. Storage_Array represents a contiguous sequence
of storage elements.
12.a Reason: The index subtype of Storage_Array is Storage_Offset because we wish to allow maximum flexibility. Most
Storage_Arrays will probably have a lower bound of 0 or 1, but other lower bounds, including negative ones, make
sense in some situations.
12.b/2 This paragraph was deleted. {AI95-00114-01}
13 Integer_Address is a [(signed or modular)] integer subtype. To_Address and To_Integer convert back and
forth between this type and Address.

```

#### *Implementation Requirements*

14 Storage\_Offset'Last shall be greater than or equal to Integer'Last or the largest possible storage offset, whichever is smaller. Storage\_Offset'First shall be  $\leq (-\text{Storage\_Offset'Last})$ .

*Paragraph 15 was deleted.*

#### *Implementation Advice*

16 Operations in System and its children should reflect the target environment semantics as closely as is reasonable. For example, on most machines, it makes sense for address arithmetic to “wrap around.” Operations that do not make sense should raise Program\_Error.

16.a.1/2 **Implementation Advice:** Operations in System and its children should reflect the target environment; operations that do not make sense should raise Program\_Error.

16.a **Discussion:** For example, on a segmented architecture,  $X < Y$  might raise Program\_Error if X and Y do not point at the same segment (assuming segments are unordered). Similarly, on a segmented architecture, the conversions between Integer\_Address and Address might not make sense for some values, and so might raise Program\_Error.

**Reason:** We considered making `Storage_Element` a private type. However, it is better to declare it as a modular type in the visible part, since code that uses it is already low level, and might as well have access to the underlying representation. We also considered allowing `Storage_Element` to be any integer type, signed integer or modular, but it is better to have uniformity across implementations in this regard, and viewing storage elements as unsigned seemed to make the most sense. 16.b

**Implementation Note:** `To_Address` is intended for use in `Address` clauses. Implementations should overload `To_Address` if appropriate. For example, on a segmented architecture, it might make sense to have a record type representing a segment/offset pair, and have a `To_Address` conversion that converts from that record type to type `Address`. 16.c

*Extensions to Ada 95*

{AI95-00362-01} Package `System.Storage_Elements` is now `Pure`, so it can be portably used in more places. (Ada 95 allowed it to be `Pure`, but did not require that.) 16.d/2

## 13.7.2 The Package `System.Address_To_Access_Conversions`

*Static Semantics*

The following language-defined generic library package exists: 1

```

generic
 type Object (<>) is limited private;
package System.Address_To_Access_Conversions is
 pragma Preelaborate(Address_To_Access_Conversions);
{AI05-0229-1} type Object_Pointer is access all Object;
 function To_Pointer(Value : Address) return Object_Pointer
 with Convention => Intrinsic;
 function To_Address(Value : Object_Pointer) return Address
 with Convention => Intrinsic;
{AI05-0229-1} end System.Address_To_Access_Conversions;

```

2  
3/3  
4/3

{AI95-00230-01} The `To_Pointer` and `To_Address` subprograms convert back and forth between values of types `Object_Pointer` and `Address`. `To_Pointer(X'Address)` is equal to `X'Unchecked_Access` for any `X` that allows `Unchecked_Access`. `To_Pointer(Null_Address)` returns `null`. For other addresses, the behavior is unspecified. `To_Address(null)` returns `Null_Address`. `To_Address(Y)`, where `Y /= null`, returns `Y.all'Address`. 5/2

**Discussion:** {AI95-00114-01} {AI05-0005-1} The programmer should ensure that the address passed to `To_Pointer` is either `Null_Address`, or the address of an object of type `Object`. (If `Object` is not a by-reference type, the object ought to be aliased; recall that the `Address` attribute is not required to provide a useful result for other objects.) Otherwise, the behavior of the program is unspecified; it might raise an exception or crash, for example. 5.a/3

**Reason:** Unspecified is almost the same thing as erroneous; they both allow arbitrarily bad behavior. We don't say erroneous here, because the implementation might allow the address passed to `To_Pointer` to point at some memory that just happens to "look like" an object of type `Object`. That's not necessarily an error; it's just not portable. However, if the actual type passed to `Object` is (for example) an array type, the programmer would need to be aware of any dope that the implementation expects to exist, when passing an address that did not come from the `Address` attribute of an object of type `Object`. 5.b

One might wonder why `To_Pointer` and `To_Address` are any better than unchecked conversions. The answer is that `Address` does not necessarily have the same representation as an access type. For example, an access value might point at the bounds of an array when an address would point at the first element. Or an access value might be an offset in words from someplace, whereas an address might be an offset in bytes from the beginning of memory. 5.c

*Implementation Permissions*

An implementation may place restrictions on instantiations of `Address_To_Access_Conversions`. 6

**Ramification:** For example, if the hardware requires aligned loads and stores, then dereferencing an access value that is not properly aligned might raise an exception. 6.a

For another example, if the implementation has chosen to use negative component offsets (from an access value), it might not be possible to preserve the semantics, since negative offsets from the `Address` are not allowed. (The `Address` attribute always points at "the first of the storage elements...") Note that while the implementation knows how to 6.b

convert an access value into an address, it might not be able to do the reverse. To avoid generic contract model violations, the restriction might have to be detected at run time in some cases.

## 13.8 Machine Code Insertions

1 [ A machine code insertion can be achieved by a call to a subprogram whose `sequence_of_statements` contains `code_statements`.]

### *Syntax*

2 `code_statement ::= qualified_expression;`

3 A `code_statement` is only allowed in the `handled_sequence_of_statements` of a `subprogram_body`. If a `subprogram_body` contains any `code_statements`, then within this `subprogram_body` the only allowed form of `statement` is a `code_statement` (labeled or not), the only allowed `declarative_items` are `use_clauses`, and no `exception_handler` is allowed (comments and pragmas are allowed as usual).

### *Name Resolution Rules*

4 The `qualified_expression` is expected to be of any type.

### *Legality Rules*

5 The `qualified_expression` shall be of a type declared in package `System.Machine_Code`.

5.a **Ramification:** This includes types declared in children of `System.Machine_Code`.

6 A `code_statement` shall appear only within the scope of a `with_clause` that mentions package `System.Machine_Code`.

6.a **Ramification:** Note that this is not a note; without this rule, it would be possible to write machine code in compilation units which depend on `System.Machine_Code` only indirectly.

### *Static Semantics*

7 The contents of the library package `System.Machine_Code` (if provided) are implementation defined. The meaning of `code_statements` is implementation defined. [Typically, each `qualified_expression` represents a machine instruction or assembly directive.]

7.a **Discussion:** For example, an instruction might be a record with an `Op_Code` component and other components for the operands.

7.b **Implementation defined:** The contents of the visible part of package `System.Machine_Code`, and the meaning of `code_statements`.

### *Implementation Permissions*

8 An implementation may place restrictions on `code_statements`. An implementation is not required to provide package `System.Machine_Code`.

#### NOTES

9 18 An implementation may provide implementation-defined pragmas specifying register conventions and calling conventions.

10/2 19 {A195-00318-02} Machine code functions are exempt from the rule that a return statement is required. In fact, return statements are forbidden, since only `code_statements` are allowed.

10.a **Discussion:** The idea is that the author of a machine code subprogram knows the calling conventions, and refers to parameters and results accordingly. The implementation should document where to put the result of a machine code function, for example, “Scalar results are returned in register 0.”

11 20 Intrinsic subprograms (see 6.3.1, “Conformance Rules”) can also be used to achieve machine code insertions. Interface to assembly language can be achieved using the features in Annex B, “Interface to Other Languages”.

## Examples

Example of a code statement:

```

{AI05-0229-1} M : Mask;
procedure Set_Mask
 with Inline;

procedure Set_Mask is
 use System.Machine_Code; -- assume “with System.Machine_Code;” appears somewhere above
begin
 SI_Format'(Code => SSM, B => M'Base_Reg, D => M'Disp);
 -- Base_Reg and Disp are implementation-defined attributes
end Set_Mask;

```

## Extensions to Ada 83

Machine code functions are allowed in Ada 95; in Ada 83, only procedures were allowed. 14.a

## Wording Changes from Ada 83

The syntax for code\_statement is changed to say “qualified\_expression” instead of “subtype\_mark'record\_aggregate”. Requiring the type of each instruction to be a record type is overspecification. 14.b

## 13.9 Unchecked Type Conversions

[ An unchecked type conversion can be achieved by a call to an instance of the generic function Unchecked\_Conversion.] 1

## Static Semantics

The following language-defined generic library function exists: 2

```

{AI05-0229-1} generic
 type Source(<>) is limited private;
 type Target(<>) is limited private;
function Ada.Unchecked_Conversion(S : Source) return Target
 with Convention => Intrinsic;
pragma Pure(Ada.Unchecked_Conversion);

```

**Reason:** {AI05-0229-1} The aspect Convention implies that the attribute Access is not allowed for instances of Unchecked\_Conversion. 3.a/3

## Dynamic Semantics

The size of the formal parameter S in an instance of Unchecked\_Conversion is that of its subtype. [This is the actual subtype passed to Source, except when the actual is an unconstrained composite subtype, in which case the subtype is constrained by the bounds or discriminants of the value of the actual expression passed to S.] 4

If all of the following are true, the effect of an unchecked conversion is to return the value of an object of the target subtype whose representation is the same as that of the source object S: 5

- S'Size = Target'Size. 6
  - Ramification:** Note that there is no requirement that the Sizes be known at compile time. 6.a
- {AI05-0078-1} S'Alignment is a multiple of Target'Alignment or Target'Alignment is zero. 7/3
- The target subtype is not an unconstrained composite subtype. 8
- S and the target subtype both have a contiguous representation. 9
- The representation of S is a representation of an object of the target subtype. 10

- 11/2 {AI95-00426-01} Otherwise, if the result type is scalar, the result of the function is implementation defined, and can have an invalid representation (see 13.9.1). If the result type is nonscalar, the effect is implementation defined; in particular, the result can be abnormal (see 13.9.1).
- 11.a.1/2 **Implementation defined:** The result of unchecked conversion for instances with scalar result types whose result is not defined by the language.
- 11.a/2 **Implementation defined:** The effect of unchecked conversion for instances with nonscalar result types whose effect is not defined by the language.
- 11.a.1/2 **Reason:** {AI95-00426-01} Note the difference between these sentences; the first only says that the bits returned are implementation defined, while the latter allows any effect. The difference is because scalar objects should never be abnormal unless their assignment was disrupted or if they are a subcomponent of an abnormal composite object. Neither exception applies to instances of Unchecked\_Conversion.
- 11.a.2/2 **Ramification:** {AI95-00426-01} Whenever unchecked conversions are used, it is the programmer's responsibility to ensure that these conversions maintain the properties that are guaranteed by the language for objects of the target type. For nonscalar types, this requires the user to understand the underlying run-time model of the implementation. The execution of a program that violates these properties by means of unchecked conversions returning a nonscalar type is erroneous. Properties of scalar types can be checked by using the Valid attribute (see 13.9.2); programs can avoid violating properties of the type (and erroneous execution) by careful use of this attribute.
- 11.b An instance of Unchecked\_Conversion can be applied to an object of a private type, assuming the implementation allows it.

*Implementation Permissions*

- 12 An implementation may return the result of an unchecked conversion by reference, if the Source type is not a by-copy type. [In this case, the result of the unchecked conversion represents simply a different (read-only) view of the operand of the conversion.]
- 12.a **Ramification:** In other words, the result object of a call on an instance of Unchecked\_Conversion can occupy the same storage as the formal parameter S.
- 13 An implementation may place restrictions on Unchecked\_Conversion.
- 13.a **Ramification:** For example, an instantiation of Unchecked\_Conversion for types for which unchecked conversion doesn't make sense may be disallowed.

*Implementation Advice*

- 14/2 {AI95-00051-02} Since the Size of an array object generally does not include its bounds, the bounds should not be part of the converted data.
- 14.a.1/2 **Implementation Advice:** Since the Size of an array object generally does not include its bounds, the bounds should not be part of the converted data in an instance of Unchecked\_Conversion.
- 14.a **Ramification:** On the other hand, we have no advice to offer about discriminants and tag fields.
- 15 The implementation should not generate unnecessary run-time checks to ensure that the representation of S is a representation of the target type. It should take advantage of the permission to return by reference when possible. Restrictions on unchecked conversions should be avoided unless required by the target environment.
- 15.a.1/2 **Implementation Advice:** There should not be unnecessary run-time checks on the result of an Unchecked\_Conversion; the result should be returned by reference when possible. Restrictions on Unchecked\_Conversions should be avoided.
- 15.a **Implementation Note:** As an example of an unnecessary run-time check, consider a record type with gaps between components. The compiler might assume that such gaps are always zero bits. If a value is produced that does not obey that assumption, then the program might misbehave. The implementation should not generate extra code to check for zero bits (except, perhaps, in a special error-checking mode).
- 16 The recommended level of support for unchecked conversions is:
- 17/3 • {AI05-0299-1} Unchecked conversions should be supported and should be reversible in the cases where this subclause defines the result. To enable meaningful use of unchecked conversion, a contiguous representation should be used for elementary subtypes, for statically constrained array

subtypes whose component subtype is one of the subtypes described in this paragraph, and for record subtypes without discriminants whose component subtypes are described in this paragraph.

**Implementation Advice:** The recommended level of support for `Unchecked_Conversion` should be followed. 17.a/2

*Wording Changes from Ada 95*

{AI95-00051-02} The implementation advice about the size of array objects was moved to 13.3 so that all of the advice about `Size` is in one place. 17.b/2

{AI95-00426-01} Clarified that the result of `Unchecked_Conversion` for scalar types can be invalid, but not abnormal. 17.c/2

*Wording Changes from Ada 2005*

{AI05-0078-1} **Correction:** Relaxed the alignment requirement slightly, giving a defined result in more cases. 17.d/3

### 13.9.1 Data Validity

Certain actions that can potentially lead to erroneous execution are not directly erroneous, but instead can cause objects to become *abnormal*. Subsequent uses of abnormal objects can be erroneous. 1

A scalar object can have an *invalid representation*, which means that the object's representation does not represent any value of the object's subtype. The primary cause of invalid representations is uninitialized variables. 2

Abnormal objects and invalid representations are explained in this subclause. 3

*Dynamic Semantics*

When an object is first created, and any explicit or default initializations have been performed, the object and all of its parts are in the *normal* state. Subsequent operations generally leave them normal. However, an object or part of an object can become *abnormal* in the following ways: 4

- An assignment to the object is disrupted due to an abort (see 9.8) or due to the failure of a language-defined check (see 11.6). 5
- {AI95-00426-01} The object is not scalar, and is passed to an **in out** or **out** parameter of an imported procedure, the `Read` procedure of an instance of `Sequential_IO`, `Direct_IO`, or `Storage_IO`, or the stream attribute `T'Read`, if after return from the procedure the representation of the parameter does not represent a value of the parameter's subtype. 6/2
- {AI95-00426-01} The object is the return object of a function call of a nonscalar type, and the function is an imported function, an instance of `Unchecked_Conversion`, or the stream attribute `T'Input`, if after return from the function the representation of the return object does not represent a value of the function's subtype. 6.1/2

**Discussion:** We explicitly list the routines involved in order to avoid future arguments. All possibilities are listed. 6.a/2

We did not include `Stream_IO.Read` in the list above. A `Stream_Element` should include all possible bit patterns, and thus it cannot be invalid. Therefore, the parameter will always represent a value of its subtype. By omitting this routine, we make it possible to write arbitrary I/O operations without any possibility of abnormal objects. 6.b/2

{AI95-00426-01} [For an imported object, it is the programmer's responsibility to ensure that the object remains in a normal state.] 6.2/2

**Proof:** This follows (and echos) the standard rule of interfacing; the programmer must ensure that Ada semantics are followed (see B.1). 6.c/2

Whether or not an object actually becomes abnormal in these cases is not specified. An abnormal object becomes normal again upon successful completion of an assignment to the object as a whole. 7

*Erroneous Execution*

8 It is erroneous to evaluate a primary that is a name denoting an abnormal object, or to evaluate a prefix that denotes an abnormal object.

8.a/2 *This paragraph was deleted. {AI95-00114-01}*

8.b **Ramification:** The **in out** or **out** parameter case does not apply to scalars; bad scalars are merely invalid representations, rather than abnormal, in this case.

8.c/2 **Reason:** {AI95-00114-01} The reason we allow access objects, and objects containing subcomponents of an access type, to become abnormal is because the correctness of an access value cannot necessarily be determined merely by looking at the bits of the object. The reason we allow scalar objects to become abnormal is that we wish to allow the compiler to optimize assuming that the value of a scalar object belongs to the object's subtype, if the compiler can prove that the object is initialized with a value that belongs to the subtype. The reason we allow composite objects to become abnormal is that such object might be represented with implicit levels of indirection; if those are corrupted, then even assigning into a component of the object, or simply asking for its Address, might have an unpredictable effect. The same is true if the discriminants have been destroyed.

*Bounded (Run-Time) Errors*

9 If the representation of a scalar object does not represent a value of the object's subtype (perhaps because the object was not initialized), the object is said to have an *invalid representation*. It is a bounded error to evaluate the value of such an object. If the error is detected, either `Constraint_Error` or `Program_Error` is raised. Otherwise, execution continues using the invalid representation. The rules of the language outside this subclause assume that all objects have valid representations. The semantics of operations on invalid representations are as follows:

9.a **Discussion:** The AARM is more explicit about what happens when the value of the case expression is an invalid representation.

9.b/2 **Ramification:** {AI95-00426-01} This includes the result object of functions, including the result of `Unchecked_Conversion`, `TInput`, and imported functions.

10 • If the representation of the object represents a value of the object's type, the value of the type is used.

11 • If the representation of the object does not represent a value of the object's type, the semantics of operations on such representations is implementation-defined, but does not by itself lead to erroneous or unpredictable execution, or to other objects becoming abnormal.

11.a/2 **Implementation Note:** {AI95-00426-01} This means that the implementation must take care not to use an invalid representation in a way that might cause erroneous execution. For instance, the exception mandated for `case_statements` must be raised. Array indexing must not cause memory outside of the array to be written (and usually, not read either). These cases and similar cases may require explicit checks by the implementation.

*Erroneous Execution*

12/3 {AI95-00167-01} {AI05-0279-1} A call to an imported function or an instance of `Unchecked_Conversion` is erroneous if the result is scalar, the result object has an invalid representation, and the result is used other than as the expression of an `assignment_statement` or an `object_declaration`, as the *object\_name* of an `object_renaming_declaration`, or as the prefix of a Valid attribute. If such a result object is used as the source of an assignment, and the assigned value is an invalid representation for the target of the assignment, then any use of the target object prior to a further assignment to the target object, other than as the prefix of a Valid attribute reference, is erroneous.

12.a/2 **Ramification:** {AI95-00167-01} In a typical implementation, every bit pattern that fits in an object of a signed integer subtype will represent a value of the type, if not of the subtype. However, for an enumeration or floating point type, as well as some modular types, there are typically bit patterns that do not represent any value of the type. In such cases, the implementation ought to define the semantics of operations on the invalid representations in the obvious manner (assuming the bounded error is not detected): a given representation should be equal to itself, a representation that is in between the internal codes of two enumeration literals should behave accordingly when passed to comparison operators and membership tests, etc. We considered *requiring* such sensible behavior, but it resulted in too much

arcane verbiage, and since implementations have little incentive to behave irrationally, such verbiage is not important to have.

{AI95-00167-01} If a stand-alone scalar object is initialized to an in-range value, then the implementation can take advantage of the fact that the use of any out-of-range value has to be erroneous. Such an out-of-range value can be produced only by things like unchecked conversion, imported functions, and abnormal values caused by disruption of an assignment due to abort or to failure of a language-defined check. This depends on out-of-range values being checked before assignment (that is, checks are not optimized away unless they are proven redundant). 12.b/2

Consider the following example: 12.c

```
{AI95-00167-01} type My_Int is range 0..99;
function Safe_Convert is new Unchecked_Conversion(My_Int, Integer);
function Unsafe_Convert is new Unchecked_Conversion(My_Int, Positive);
X : Positive := Safe_Convert(0); -- Raises Constraint_Error.
Y : Positive := Unsafe_Convert(0); -- Bounded Error, may be invalid.
B : Boolean := Y'Valid; -- OK, B = False.
Z : Positive := Y+1; -- Erroneous to use Y.
```

12.d/2

{AI95-00167-01} {AI95-00426-01} The call to Unsafe\_Convert is a bounded error, which might raise Constraint\_Error, Program\_Error, or return an invalid value. Moreover, if an exception is not raised, most uses of that invalid value (including the use of Y) cause erroneous execution. The call to Safe\_Convert is not erroneous. The result object is an object of subtype Integer containing the value 0. The assignment to X is required to do a constraint check; the fact that the conversion is unchecked does not obviate the need for subsequent checks required by the language rules. 12.e/2

{AI95-00167-01} {AI95-00426-01} The reason for delaying erroneous execution until the object is used is so that the invalid representation can be tested for validity using the Valid attribute (see 13.9.2) without causing execution to become erroneous. Note that this delay does not imply an exception will not be raised; an implementation could treat both conversions in the example in the same way and raise Constraint\_Error. 12.e.1/2

{AI05-0279-1} The rules are defined in terms of the result object, and thus the name used to reference that object is irrelevant. That is why we don't need any special rules to describe what happens when the function result is renamed. 12.e.2/3

**Implementation Note:** If an implementation wants to have a “friendly” mode, it might always assign an uninitialized scalar a default initial value that is outside the object's subtype (if there is one), and check for this value on some or all reads of the object, so as to help detect references to uninitialized scalars. Alternatively, an implementation might want to provide an “unsafe” mode where it presumed even uninitialized scalars were always within their subtype. 12.f

**Ramification:** The above rules imply that it is a bounded error to apply a predefined operator to an object with a scalar subcomponent having an invalid representation, since this implies reading the value of each subcomponent. Either Program\_Error or Constraint\_Error is raised, or some result is produced, which if composite, might have a corresponding scalar subcomponent still with an invalid representation. 12.g

Note that it is not an error to assign, convert, or pass as a parameter a composite object with an uninitialized scalar subcomponent. In the other hand, it is a (bounded) error to apply a predefined operator such as =, <, and xor to a composite operand with an invalid scalar subcomponent. 12.h

{AI05-0054-2} The dereference of an access value is erroneous if it does not designate an object of an appropriate type or a subprogram with an appropriate profile, if it designates a nonexistent object, or if it is an access-to-variable value that designates a constant object and it did not originate from an attribute\_reference applied to an aliased variable view of a controlled or immutably limited object. [An access value whose dereference is erroneous can exist, for example, because of Unchecked\_Deallocation, Unchecked\_Access, or Unchecked\_Conversion.] 13/3

**Ramification:** The above mentioned Unchecked\_... features are not the only causes of such access values. For example, interfacing to other languages can also cause the problem. 13.a

{AI05-0054-2} We permit the use of access-to-variable values that designate constant objects so long as they originate from an aliased variable view of a controlled or immutably limited constant, such as during the initialization of a constant (both via the “current instance” and during a call to Initialize) or during an assignment (during a call to Adjust). 13.b/3

#### NOTES

21 Objects can become abnormal due to other kinds of actions that directly update the object's representation; such actions are generally considered directly erroneous, however. 14

#### Wording Changes from Ada 83

In order to reduce the amount of erroneousness, we separate the concept of an undefined value into objects with invalid representation (scalars only) and abnormal objects. 14.a

- 14.b Reading an object with an invalid representation is a bounded error rather than erroneous; reading an abnormal object is still erroneous. In fact, the only safe thing to do to an abnormal object is to assign to the object as a whole.

*Wording Changes from Ada 95*

- 14.c/2 {AI95-00167-01} The description of erroneous execution for Unchecked\_Conversion and imported objects was tightened up so that using the Valid attribute to test such a value is not erroneous.
- 14.d/2 {AI95-00426-01} Clarified the definition of objects that can become abnormal; made sure that all of the possibilities are included.

*Wording Changes from Ada 2005*

- 14.e/3 {AI05-0054-2} **Correction:** Common programming techniques such as squirreling away an access to a controlled object during initialization and using a self-referencing discriminant (the so-called “Rosen trick”) no longer are immediately erroneous if the object is declared constant, so these techniques can be used portably and safely. Practically, these techniques already worked as compilers did not take much advantage of this rule, so the impact of this change will be slight.
- 14.f/3 {AI05-0279-1} **Correction:** The description of erroneous execution for Unchecked\_Conversion and imported objects was adjusted to clarify that renaming such an object is not, by itself, erroneous.

## 13.9.2 The Valid Attribute

- 1 The Valid attribute can be used to check the validity of data produced by unchecked conversion, input, interface to foreign languages, and the like.

*Static Semantics*

- 2 For a prefix X that denotes a scalar object [(after any implicit dereference)], the following attribute is defined:

- 3/3 X'Valid {AI05-0153-3} Yields True if and only if the object denoted by X is normal, has a valid representation, and the predicate of the nominal subtype of X evaluates to True. The value of this attribute is of the predefined type Boolean.

- 3.a **Ramification:** Having checked that X'Valid is True, it is safe to read the value of X without fear of erroneous execution caused by abnormality, or a bounded error caused by an invalid representation. Such a read will produce a value in the subtype of X.

### NOTES

- 4 22 Invalid data can be created in the following cases (not counting erroneous or unpredictable execution):
- 5 • an uninitialized scalar object,
  - 6 • the result of an unchecked conversion,
  - 7 • input,
  - 8 • interface to another language (including machine code),
  - 9 • aborting an assignment,
  - 10 • disrupting an assignment due to the failure of a language-defined check (see 11.6), and
  - 11 • use of an object whose Address has been specified.
- 12 23 X'Valid is not considered to be a read of X; hence, it is not an error to check the validity of invalid data.
- 13/2 24 {AI95-00426-01} The Valid attribute may be used to check the result of calling an instance of Unchecked\_Conversion (or any other operation that can return invalid values). However, an exception handler should also be provided because implementations are permitted to raise Constraint\_Error or Program\_Error if they detect the use of an invalid representation (see 13.9.1).
- 13.a **Ramification:** If X is of an enumeration type with a representation clause, then X'Valid checks that the value of X when viewed as an integer is one of the specified internal codes.
- 13.b **Reason:** Valid is defined only for scalar objects because the implementation and description burden would be too high for other types. For example, given a typical run-time model, it is impossible to check the validity of an access value. The same applies to composite types implemented with internal pointers. One can check the validity of a composite object by checking the validity of each of its scalar subcomponents. The user should ensure that any composite types

that need to be checked for validity are represented in a way that does not involve implementation-defined components, or gaps between components. Furthermore, such types should not contain access subcomponents.

*This paragraph was deleted. {AI95-00114-01}*

13.c/2

*Extensions to Ada 83*

X'Valid is new in Ada 95.

13.d

*Wording Changes from Ada 95*

{AI95-00426-01} Added a note explaining that handlers for Constraint\_Error and Program\_Error are needed in the general case of testing for validity. (An implementation could document cases where these are not necessary, but there is no language requirement.)

13.e/2

*Wording Changes from Ada 2005*

{AI05-0153-3} The validity check now also includes a check of the predicate aspects (see 3.2.4), if any, of the subtype of the object.

13.f/3

## 13.10 Unchecked Access Value Creation

[The attribute Unchecked\_Access is used to create access values in an unsafe manner — the programmer is responsible for preventing “dangling references.”]

1

*Static Semantics*

The following attribute is defined for a prefix X that denotes an aliased view of an object:

2

X'Unchecked\_Access

3

All rules and semantics that apply to X'Access (see 3.10.2) apply also to X'Unchecked\_Access, except that, for the purposes of accessibility rules and checks, it is as if X were declared immediately within a library package.

**Ramification:** {AI05-0005-1} We say “rules and semantics” here so that library-level accessibility applies to the value created by X'Unchecked\_Access as well as to the checks needed for the attribute itself. This means that any anonymous access values that inherit the accessibility of this attribute (such as access parameters) also act as if they have library-level accessibility. We don't want the “real” accessibility of the created value re-emerging at a later point — that would create hard-to-understand bugs.

3.a/3

### NOTES

25 This attribute is provided to support the situation where a local object is to be inserted into a global linked data structure, when the programmer knows that it will always be removed from the data structure prior to exiting the object's scope. The Access attribute would be illegal in this case (see 3.10.2, “Operations of Access Types”).

4

**Ramification:** The expected type for X'Unchecked\_Access is as for X'Access.

4.a

If an attribute\_reference with Unchecked\_Access is used as the actual parameter for an access parameter, an Accessibility\_Check can never fail on that access parameter.

4.b

26 There is no Unchecked\_Access attribute for subprograms.

5

**Reason:** {AI95-00254-01} Such an attribute would allow unsafe “downward closures”, where an access value designating a more nested subprogram is passed to a less nested subprogram. (Anonymous access-to-subprogram parameters provide safe “downward closures”.) This requires some means of reconstructing the global environment for the more nested subprogram, so that it can do up-level references to objects. The two methods of implementing up-level references are displays and static links. If unsafe downward closures were supported, each access-to-subprogram value would have to carry the static link or display with it. We don't want to require the space and time overhead of requiring the extra information for all access-to-subprogram types, especially as including it would make interfacing to other languages (like C) harder.

5.a/2

If desired, an instance of Unchecked\_Conversion can be used to create an access value of a global access-to-subprogram type that designates a local subprogram. The semantics of using such a value are not specified by the language. In particular, it is not specified what happens if such subprograms make up-level references; even if the frame being referenced still exists, the up-level reference might go awry if the representation of a value of a global access-to-subprogram type doesn't include a static link.

5.b

## 13.11 Storage Management

1 [ Each access-to-object type has an associated storage pool. The storage allocated by an `allocator` comes from the pool; instances of `Unchecked_Deallocation` return storage to the pool. Several access types can share the same pool.]

2/2 {AI95-00435-01} [A storage pool is a variable of a type in the class rooted at `Root_Storage_Pool`, which is an abstract limited controlled type. By default, the implementation chooses a *standard storage pool* for each access-to-object type. The user may define new pool types, and may override the choice of pool for an access-to-object type by specifying `Storage_Pool` for the type.]

2.a **Ramification:** By default, the implementation might choose to have a single global storage pool, which is used (by default) by all access types, which might mean that storage is reclaimed automatically only upon partition completion. Alternatively, it might choose to create a new pool at each accessibility level, which might mean that storage is reclaimed for an access type when leaving the appropriate scope. Other schemes are possible.

2.a.1/3 **Glossary entry:** Each access-to-object type has an associated storage pool object. The storage for an object created by an `allocator` comes from the storage pool of the type of the `allocator`. Some storage pools may be partitioned into subpools in order to support finer-grained storage management.

### Legality Rules

3 If `Storage_Pool` is specified for a given access type, `Storage_Size` shall not be specified for it.

3.a **Reason:** The `Storage_Pool` determines the `Storage_Size`; hence it would not make sense to specify both. Note that this rule is simplified by the fact that the aspects in question cannot be specified for derived types, nor for nonfirst subtypes, so we don't have to worry about whether, say, `Storage_Pool` on a derived type overrides `Storage_Size` on the parent type. For the same reason, “specified” means the same thing as “directly specified” here.

### Static Semantics

4 The following language-defined library package exists:

```
5 with Ada.Finalization;
6 with System.Storage_Elements;
7 package System.Storage_Pools is
8 pragma Preelaborate(System.Storage_Pools);
9 {AI95-00161-01} type Root_Storage_Pool is
10 abstract new Ada.Finalization.Limited_Controlled with private;
11 pragma Preelaborable_Initialization(Root_Storage_Pool);
12
13 procedure Allocate(
14 Pool : in out Root_Storage_Pool;
15 Storage_Address : out Address;
16 Size_In_Storage_Elements : in Storage_Elements.Storage_Count;
17 Alignment : in Storage_Elements.Storage_Count) is abstract;
18
19 procedure Deallocate(
20 Pool : in out Root_Storage_Pool;
21 Storage_Address : in Address;
22 Size_In_Storage_Elements : in Storage_Elements.Storage_Count;
23 Alignment : in Storage_Elements.Storage_Count) is abstract;
24
25 function Storage_Size(Pool : Root_Storage_Pool)
26 return Storage_Elements.Storage_Count is abstract;
27
28 private
29 ... -- not specified by the language
30 end System.Storage_Pools;
```

10.a **Reason:** The `Alignment` parameter is provided to `Deallocate` because some allocation strategies require it. If it is not needed, it can be ignored.

11 A *storage pool type* (or *pool type*) is a descendant of `Root_Storage_Pool`. The *elements* of a storage pool are the objects allocated in the pool by `allocators`.

- Discussion:** In most cases, an element corresponds to a single memory block allocated by `Allocate`. However, in some cases the implementation may choose to associate more than one memory block with a given pool element. 11.a
- {8652/0009} {AI95-00137-01} {AI95-00435-01} For every access-to-object subtype `S`, the following representation attributes are defined: 12/2
- `S'Storage_Pool` 13  
Denotes the storage pool of the type of `S`. The type of this attribute is `Root_Storage_Pool'Class`.
- `S'Storage_Size` 14  
Yields the result of calling `Storage_Size(S'Storage_Pool)`[, which is intended to be a measure of the number of storage elements reserved for the pool.] The type of this attribute is *universal\_integer*.
- Ramification:** `Storage_Size` is also defined for task subtypes and objects — see 13.3. 14.a
- `Storage_Size` is not a measure of how much un-allocated space is left in the pool. That is, it includes both allocated and unallocated space. Implementations and users may provide a `Storage_Available` function for their pools, if so desired. 14.b
- `Storage_Size` or `Storage_Pool` may be specified for a nonderived access-to-object type via an `attribute_definition_clause`; the name in a `Storage_Pool` clause shall denote a variable. 15
- Aspect Description for `Storage_Pool`:** Pool of memory from which `new` will allocate for a given access type. 15.a/3
- Aspect Description for `Storage_Size` (access):** Sets memory size for allocations for an access type. 15.b/3
- {AI05-0107-1} {AI05-0111-3} {AI05-0116-1} An allocator of a type `T` that does not support subpools allocates storage from `T`'s storage pool. If the storage pool is a user-defined object, then the storage is allocated by calling `Allocate` as described below. Allocators for types that support subpools are described in 13.11.4. 16/3
- Ramification:** If the implementation chooses to represent the designated subtype in multiple pieces, one allocator evaluation might result in more than one call upon `Allocate`. In any case, allocators for the access type obtain all the required storage for an object of the designated type by calling the specified `Allocate` procedure. 16.a
- This paragraph was deleted.* {AI05-0107-1} 16.b/3
- {8652/0111} {AI95-00103-01} If `D` (the designated type of `T`) includes subcomponents of other access types, they will be allocated from the storage pools for those types, even if those allocators are executed as part of the allocator of `T` (as part of the initialization of the object). For instance, an access-to-task type `TT` may allocate the data structures used to implement the task value from other storage pools. (In particular, the task stack does not necessarily need to be allocated from the storage pool for `TT`.) 16.b.1/1
- If `Storage_Pool` is not specified for a type defined by an `access_to_object_definition`, then the implementation chooses a standard storage pool for it in an implementation-defined manner. In this case, the exception `Storage_Error` is raised by an allocator if there is not enough storage. It is implementation defined whether or not the implementation provides user-accessible names for the standard pool type(s). 17
- This paragraph was deleted.* 17.a/2
- Discussion:** The manner of choosing a storage pool is covered by a Documentation Requirement below, so it is not summarized here. 17.a.1/2
- Implementation defined:** Whether or not the implementation provides user-accessible names for the standard pool type(s). 17.b
- Ramification:** {AI95-00230-01} An access-to-object type defined by a `derived_type_definition` inherits its pool from its parent type, so all access-to-object types in the same derivation class share the same pool. Hence the “defined by an `access_to_object_definition`” wording above. 17.c/2
- There is no requirement that all storage pools be implemented using a contiguous block of memory (although each allocation returns a pointer to a contiguous block of memory). 17.d
- If `Storage_Size` is specified for an access type, then the `Storage_Size` of this pool is at least that requested, and the storage for the pool is reclaimed when the master containing the declaration of the access type is left. If the implementation cannot satisfy the request, `Storage_Error` is raised at the point of the `attribute_`- 18

definition\_clause. If neither Storage\_Pool nor Storage\_Size are specified, then the meaning of Storage\_Size is implementation defined.

- 18.a/2      **Implementation defined:** The meaning of Storage\_Size when neither the Storage\_Size nor the Storage\_Pool is specified for an access type.
- 18.b      **Ramification:** The Storage\_Size function and attribute will return the actual size, rather than the requested size. Comments about rounding up, zero, and negative on task Storage\_Size apply here, as well. See also AI83-00557, AI83-00558, and AI83-00608.
- 18.c      The expression in a Storage\_Size clause need not be static.
- 18.d      The reclamation happens after the master is finalized.
- 18.e      **Implementation Note:** For a pool allocated on the stack, normal stack cut-back can accomplish the reclamation. For a library-level pool, normal partition termination actions can accomplish the reclamation.
- 19      If Storage\_Pool is specified for an access type, then the specified pool is used.
- 20      The effect of calling Allocate and Deallocate for a standard storage pool directly (rather than implicitly via an allocator or an instance of Unchecked\_Deallocation) is unspecified.
- 20.a      **Ramification:** For example, an allocator might put the pool element on a finalization list. If the user directly Deallocates it, instead of calling an instance of Unchecked\_Deallocation, then the implementation would probably try to finalize the object upon master completion, which would be bad news. Therefore, the implementation should define such situations as erroneous.

*Erroneous Execution*

- 21      If Storage\_Pool is specified for an access type, then if Allocate can satisfy the request, it should allocate a contiguous block of memory, and return the address of the first storage element in Storage\_Address. The block should contain Size\_In\_Storage\_Elements storage elements, and should be aligned according to Alignment. The allocated storage should not be used for any other purpose while the pool element remains in existence. If the request cannot be satisfied, then Allocate should propagate an exception [(such as Storage\_Error)]. If Allocate behaves in any other manner, then the program execution is erroneous.

*Implementation Requirements*

- 21.1/3    {AI05-0107-1} {AI05-0262-1} The Allocate procedure of a user-defined storage pool object *P* may be called by the implementation only to allocate storage for a type *T* whose pool is *P*, only at the following points:
  - 21.2/3    • During the execution of an allocator of type *T*;
  - 21.a/3      **Ramification:** This includes during the evaluation of the initializing expression such as an aggregate; this is important if the initializing expression is built in place. We need to allow allocation to be deferred until the size of the object is known.
  - 21.3/3    • During the execution of a return statement for a function whose result is built-in-place in the result of an allocator of type *T*;
  - 21.b/3      **Reason:** We need this bullet as well as the preceding one in order that exceptions that propagate from such a call to Allocate can be handled within the return statement. We don't want to require the generation of special handling code in this unusual case, as it would add overhead to most return statements of composite types.
  - 21.4/3    • During the execution of an assignment operation with a target of an allocated object of type *T* with a part that has an unconstrained discriminated subtype with defaults.
  - 21.c/3      **Reason:** We allow Allocate to be called during assignment of objects with mutable parts so that mutable objects can be implemented with reallocation on assignment. (Unfortunately, the term "mutable" is only defined in the AARM, so we have to use the long-winded wording shown here.)
  - 21.d/3      **Discussion:** Of course, explicit calls to Allocate are also allowed and are not bound by any of the rules found here.
- 21.5/3    {AI05-0107-1} {AI05-0116-1} {AI05-0193-1} {AI05-0262-1} {AI05-0269-1} For each of the calls of Allocate described above, *P* (equivalent to *T*'Storage\_Pool) is passed as the Pool parameter. The

Size\_In\_Storage\_Elements parameter indicates the number of storage elements to be allocated, and is no more than  $D\text{Max\_Size\_In\_Storage\_Elements}$ , where  $D$  is the designated subtype of  $T$ . The Alignment parameter is a nonzero integral multiple of  $D\text{Alignment}$  if  $D$  is a specific type, and otherwise is a nonzero integral multiple of the alignment of the specific type identified by the tag of the object being created; it is unspecified if there is no such value. The Alignment parameter is no more than  $D\text{Max\_Alignment\_For\_Allocation}$ . The result returned in the Storage\_Address parameter is used as the address of the allocated storage, which is a contiguous block of memory of Size\_In\_Storage\_Elements storage elements. [Any exception propagated by Allocate is propagated by the construct that contained the call.]

**Ramification:** Note that the implementation does not turn other exceptions into Storage\_Error. 21.e/3

“Nonzero integral multiple” of an alignment includes the alignment value itself, of course. The value is unspecified if the alignment of the specific type is zero. 21.f/3

{AI05-0107-1} The number of calls to Allocate needed to implement an allocator for any particular type is unspecified. The number of calls to Deallocate needed to implement an instance of Unchecked\_Deallocation (see 13.11.2) for any particular object is the same as the number of Allocate calls for that object. 21.6/3

**Reason:** This supports objects that are allocated in one or more parts. The second sentence prevents extra or missing calls to Deallocate. 21.g/3

**To be honest:** {AI05-0005-1} The number of calls to Deallocate from all sources for an object always will be the same as the number of calls to Allocate from all sources for that object. However, in unusual cases, not all of those Deallocate calls may be made by an instance of Unchecked\_Deallocation. Specifically, in the unusual case of assigning to an object of a mutable variant record type such that the variant changes, some of the Deallocate calls may be made by the assignment (as may some of the Allocate calls). 21.h/3

**Ramification:** We do not define the relative order of multiple calls used to deallocate the same object — that is, if the allocator allocated two pieces  $x$  and  $y$ , then an instance of Unchecked\_Deallocation might deallocate  $x$  and then  $y$ , or it might deallocate  $y$  and then  $x$ . 21.i/3

{AI05-0107-1} The Deallocate procedure of a user-defined storage pool object  $P$  may be called by the implementation to deallocate storage for a type  $T$  whose pool is  $P$  only at the places when an Allocate call is allowed for  $P$ , during the execution of an instance of Unchecked\_Deallocation for  $T$ , or as part of the finalization of the collection of  $T$ . For such a call of Deallocate,  $P$  (equivalent to  $T\text{Storage\_Pool}$ ) is passed as the Pool parameter. The value of the Storage\_Address parameter for a call to Deallocate is the value returned in the Storage\_Address parameter of the corresponding successful call to Allocate. The values of the Size\_In\_Storage\_Elements and Alignment parameters are the same values passed to the corresponding Allocate call. Any exception propagated by Deallocate is propagated by the construct that contained the call. 21.7/3

**Reason:** We allow Deallocate to be called anywhere that Allocate is, in order to allow the recovery of storage from failed allocations (that is, those that raise exceptions); from extended return statements that exit via a goto, exit, or locally handled exception; and from objects that are reallocated when they are assigned. In each of these cases, we would have a storage leak if the implementation did not recover the storage (there is no way for the programmer to do it). We do not require such recovery, however, as it could be a serious performance drag on these operations. 21.j/3

#### Documentation Requirements

An implementation shall document the set of values that a user-defined Allocate procedure needs to accept for the Alignment parameter. An implementation shall document how the standard storage pool is chosen, and how storage is allocated by standard storage pools. 22

*This paragraph was deleted.* 22.a/2

**Documentation Requirement:** The set of values that a user-defined Allocate procedure needs to accept for the Alignment parameter. How the standard storage pool is chosen, and how storage is allocated by standard storage pools. 22.b/2

*Implementation Advice*

- 23 An implementation should document any cases in which it dynamically allocates heap storage for a purpose other than the evaluation of an allocator.
- 23.a.1/2 **Implementation Advice:** Any cases in which heap storage is dynamically allocated other than as part of the evaluation of an allocator should be documented.
- 23.a **Reason:** This is “Implementation Advice” because the term “heap storage” is not formally definable; therefore, it is not testable whether the implementation obeys this advice.
- 24 A default (implementation-provided) storage pool for an access-to-constant type should not have overhead to support deallocation of individual objects.
- 24.a.1/2 **Implementation Advice:** A default storage pool for an access-to-constant type should not have overhead to support deallocation of individual objects.
- 24.a **Ramification:** Unchecked\_Deallocation is not defined for such types. If the access-to-constant type is library-level, then no deallocation (other than at partition completion) will ever be necessary, so if the size needed by an allocator of the type is known at link-time, then the allocation should be performed statically. If, in addition, the initial value of the designated object is known at compile time, the object can be allocated to read-only memory.
- 24.b **Implementation Note:** If the Storage\_Size for an access type is specified, the storage pool should consist of a contiguous block of memory, possibly allocated on the stack. The pool should contain approximately this number of storage elements. These storage elements should be reserved at the place of the Storage\_Size clause, so that allocators cannot raise Storage\_Error due to running out of pool space until the appropriate number of storage elements has been used up. This approximate (possibly rounded-up) value should be used as a maximum; the implementation should not increase the size of the pool on the fly. If the Storage\_Size for an access type is specified as zero, then the pool should not take up any storage space, and any allocator for the type should raise Storage\_Error.
- 24.c **Ramification:** Note that most of this is approximate, and so cannot be (portably) tested. That's why we make it an Implementation Note. There is no particular number of allocations that is guaranteed to succeed, and there is no particular number of allocations that is guaranteed to fail.
- 25/2 {AI95-00230-01} The storage pool used for an allocator of an anonymous access type should be determined as follows:
- 25.1/2 • {AI95-00230-01} {AI95-00416-01} If the allocator is defining a coextension (see 3.10.2) of an object being created by an outer allocator, then the storage pool used for the outer allocator should also be used for the coextension;
- 25.2/2 • {AI95-00230-01} For other access discriminants and access parameters, the storage pool should be created at the point of the allocator, and be reclaimed when the allocated object becomes inaccessible;
- 25.3/3 • {AI05-0051-1} If the allocator defines the result of a function with an access result, the storage pool is determined as though the allocator were in place of the call of the function. If the call is the operand of a type conversion, the storage pool is that of the target access type of the conversion. If the call is itself defining the result of a function with an access result, this rule is applied recursively;
- 25.4/2 • {AI95-00230-01} Otherwise, a default storage pool should be created at the point where the anonymous access type is elaborated; such a storage pool need not support deallocation of individual objects.
- 25.a.1/2 **Implementation Advice:** Usually, a storage pool for an access discriminant or access parameter should be created at the point of an allocator, and be reclaimed when the designated object becomes inaccessible. For other anonymous access types, the pool should be created at the point where the type is elaborated and need not support deallocation of individual objects.
- 25.a/2 **Implementation Note:** {AI95-00230-01} For access parameters and access discriminants, the "storage pool" for an anonymous access type would not normally exist as a separate entity. Instead, the designated object of the allocator would be allocated, in the case of an access parameter, as a local aliased variable at the call site, and in the case of an access discriminant, contiguous with the object containing the discriminant. This is similar to the way storage for aggregates is typically managed.
- 25.b/2 {AI95-00230-01} For other sorts of anonymous access types, this implementation is not possible in general, as the accessibility of the anonymous access type is that of its declaration, while the allocator could be more nested. In this

case, a "real" storage pool is required. Note, however, that this storage pool need not support (separate) deallocation, as it is not possible to instantiate `Unchecked_Deallocation` with an anonymous access type. (If deallocation is needed, the object should be allocated for a named access type and converted.) Thus, deallocation only need happen when the anonymous access type itself goes out of scope; this is similar to the case of an access-to-constant type.

## NOTES

- 27 A user-defined storage pool type can be obtained by extending the `Root_Storage_Pool` type, and overriding the primitive subprograms `Allocate`, `Deallocate`, and `Storage_Size`. A user-defined storage pool can then be obtained by declaring an object of the type extension. The user can override `Initialize` and `Finalize` if there is any need for nontrivial initialization and finalization for a user-defined pool type. For example, `Finalize` might reclaim blocks of storage that are allocated separately from the pool object itself. 26
- 28 The writer of the user-defined allocation and deallocation procedures, and users of allocators for the associated access type, are responsible for dealing with any interactions with tasking. In particular: 27
- If the allocators are used in different tasks, they require mutual exclusion. 28
  - If they are used inside protected objects, they cannot block. 29
  - If they are used by interrupt handlers (see C.3, "Interrupt Support"), the mutual exclusion mechanism has to work properly in that context. 30
- 29 The primitives `Allocate`, `Deallocate`, and `Storage_Size` are declared as abstract (see 3.9.3), and therefore they have to be overridden when a new (nonabstract) storage pool type is declared. 31
- Ramification:** Note that the `Storage_Pool` attribute denotes an object, rather than a value, which is somewhat unusual for attributes. 31.a
- The calls to `Allocate`, `Deallocate`, and `Storage_Size` are dispatching calls — this follows from the fact that the actual parameter for `Pool` is `T'Storage_Pool`, which is of type `Root_Storage_Pool'Class`. In many cases (including all cases in which `Storage_Pool` is not specified), the compiler can determine the tag statically. However, it is possible to construct cases where it cannot. 31.b
- All access types in the same derivation class share the same pool, whether implementation defined or user defined. This is necessary because we allow type conversions among them (even if they are pool-specific), and we want pool-specific access values to always designate an element of the right pool. 31.c
- Implementation Note:** If an access type has a standard storage pool, then the implementation doesn't actually have to follow the pool interface described here, since this would be semantically invisible. For example, the allocator could conceivably be implemented with inline code. 31.d

*Examples*

To associate an access type with a storage pool object, the user first declares a pool object of some type derived from `Root_Storage_Pool`. Then, the user defines its `Storage_Pool` attribute, as follows: 32

```
Pool_Object : Some_Storage_Pool_Type; 33
type T is access Designated; 34
for T'Storage_Pool use Pool_Object;
```

Another access type may be added to an existing storage pool, via: 35

```
for T2'Storage_Pool use T'Storage_Pool; 36
```

The semantics of this is implementation defined for a standard storage pool. 37

**Reason:** For example, the implementation is allowed to choose a storage pool for `T` that takes advantage of the fact that `T` is of a certain size. If `T2` is not of that size, then the above will probably not work. 37.a

{AI05-0111-3} As usual, a derivative of `Root_Storage_Pool` may define additional operations. For example, consider the `Mark_Release_Pool_Type` defined in 13.11.6, that has two additional operations, `Mark` and `Release`, the following is a possible use: 38/3

```
{8652/0041} {AI95-00066-01} {AI05-0111-3} type Mark_Release_Pool_Type 39/3
(Pool_Size : Storage_Elements.Storage_Count)
is new Subpools.Root_Storage_Pool_With_Subpools with private;
-- As defined in package MR_Pool, see 13.11.6
... 40
{AI05-0111-3} Our_Pool : Mark_Release_Pool_Type (Pool_Size => 2000); 41/3
My_Mark : MR_Pool.Subpool_Handle; -- See 13.11.6
```

```
42/3 {AI05-0111-3} type Acc is access ... ;
 for Acc'Storage_Pool use Our_Pool;
 ...
43/3 {AI05-0111-3} My_Mark := Mark(Our_Pool);
 ... -- Allocate objects using "new (My_Mark) Designated(...)".
 Release(My_Mark); -- Finalize objects and reclaim storage.
```

*Extensions to Ada 83*

43.a User-defined storage pools are new to Ada 95.

*Wording Changes from Ada 83*

43.b/3 {AI05-0005-1} {AI05-0190-1} Ada 83 originally introduced the concept called a “collection,” which is similar to what we call a storage pool. All access types in the same derivation class share the same collection. Ada 95 introduces the storage pool, which is similar in that all access types in the same derivation class share the same storage pool, but other (unrelated) access types can also share the same storage pool, either by default, or as specified by the user. A collection is an amorphous grouping of objects (mainly used to describe finalization of access types); a storage pool is a more concrete concept — hence the different name.

43.c RM83 states the erroneous nature of reading or updating deallocated objects incorrectly by missing various cases.

*Incompatibilities With Ada 95*

43.d/2 {AI95-00435-01} **Amendment Correction:** Storage pools (and Storage\_Size) are not defined for access-to-subprogram types. The original Ada 95 wording defined the attributes, but said nothing about their values. If a program uses attributes Storage\_Pool or Storage\_Size on an access-to-subprogram type, it will need to be corrected for Ada 2005. That's a good thing, as such a use is a bug — the concepts never were defined for such types.

*Extensions to Ada 95*

43.e/2 {AI95-00161-01} **Amendment Correction:** Added pragma Preelaborable\_Initialization to type Root\_Storage\_Pool, so that extensions of it can be used to declare default-initialized objects in preelaborated units.

*Wording Changes from Ada 95*

43.f/2 {8652/0009} {AI95-00137-01} **Corrigendum:** Added wording to specify that these are representation attributes.

43.g/2 {AI95-00230-01} {AI95-00416-01} Added wording to clarify that an allocator for a coextension nested inside an outer allocator shares the pool with the outer allocator.

*Wording Changes from Ada 2005*

43.h/3 {AI05-0051-1} **Correction:** Added the missing definition of the storage pool of an allocator for an anonymous access result type.

43.i/3 {AI05-0107-1} **Correction:** Clarified when an implementation is allowed to call Allocate and Deallocate, and the requirements on such calls.

43.j/3 {AI05-0111-3} Added wording to support subpools and refer to the subpool example, see 13.11.4.

43.k/3 {AI05-0116-1} **Correction:** Added wording to specify that the alignment for an allocator with a class-wide designated type comes from the specific type that is allocated.

43.l/3 {AI05-0193-1} Added wording to allow larger alignments for calls to Allocate made by allocators, up to Max\_Alignment\_For\_Allocation. This eases implementation in some cases.

### 13.11.1 Storage Allocation Attributes

1/3 {AI05-0193-1} [The Max\_Size\_In\_Storage\_Elements and Max\_Alignment\_For\_Allocation attributes may be useful in writing user-defined pool types.]

*Static Semantics*

2/3 {AI05-0193-1} For every subtype S, the following attributes are defined:

- S'Max\_Size\_In\_Storage\_Elements** 3/3  
 {AI95-00256-01} {AI95-00416-01} {AI05-0193-1} Denotes the maximum value for `Size_In_Storage_Elements` that could be requested by the implementation via `Allocate` for an access type whose designated subtype is `S`. The value of this attribute is of type *universal\_integer*.
- Ramification:** If `S` is an unconstrained array subtype, or an unconstrained subtype with discriminants, `S'Max_Size_In_Storage_Elements` might be very large. 3.a
- S'Max\_Alignment\_For\_Allocation** 4/3  
 {AI05-0193-1} Denotes the maximum value for `Alignment` that could be requested by the implementation via `Allocate` for an access type whose designated subtype is `S`. The value of this attribute is of type *universal\_integer*.
- {AI05-0193-1} For a type with access discriminants, if the implementation allocates space for a coextension in the same pool as that of the object having the access discriminant, then these attributes account for any calls on `Allocate` that could be performed to provide space for such coextensions. 5/3
- Reason:** {AI05-0193-1} The values of these attributes should reflect only the calls that might be made to the pool specified for an access type with designated type `S`. Thus, if the coextensions would normally be allocated from a different pool than the one used for the main object (that is, the Implementation Advice of 13.11 for determining the pool of an anonymous access discriminant is not followed), then these attributes should not reflect any calls on `Allocate` used to allocate the coextensions. 5.a/3
- Ramification:** {AI05-0193-1} Coextensions of coextensions of this type (and so on) are included in the values of these attributes if they are allocated from the same pool. 5.b/3
- Wording Changes from Ada 95*
- {AI95-00256-01} Corrected the wording so that a fortune-telling compiler that can see the future execution of the program is not required. 5.c/2
- Extensions to Ada 2005*
- {AI05-0193-1} The `Max_Alignment_For_Allocation` attribute is new. 5.d/3

## 13.11.2 Unchecked Storage Deallocation

[ Unchecked storage deallocation of an object designated by a value of an access type is achieved by a call to an instance of the generic procedure `Unchecked_Deallocation`.] 1

### *Static Semantics*

- The following language-defined generic library procedure exists: 2
- ```
{AI05-0229-1} generic
  type Object (<>) is limited private;
  type Name is access Object;
  procedure Ada.Unchecked_Deallocation(X : in out Name)
  with Convention => Intrinsic;
  pragma Preelaborate (Ada.Unchecked_Deallocation);
```
- Reason:** {AI05-0229-1} The aspect `Convention` implies that the attribute `Access` is not allowed for instances of `Unchecked_Deallocation`. 3.a/3

Legality Rules

- {AI05-0157-1} A call on an instance of `Unchecked_Deallocation` is illegal if the actual access type of the instance is a type for which the `Storage_Size` has been specified by a static expression with value zero or is defined by the language to be zero. In addition to the places where Legality Rules normally apply (see 12.3), this rule applies also in the private part of an instance of a generic unit. 3.1/3

3.b/3 **Discussion:** This rule is the same as the rule for allocators. We could have left the last sentence out, as a call to `Unchecked_Deallocation` cannot occur in a specification as it is a procedure call, but we left it for consistency and to avoid future maintenance hazards.

Dynamic Semantics

4 Given an instance of `Unchecked_Deallocation` declared as follows:

```
5   procedure Free is
      new Ada.Unchecked_Deallocation(
          object_subtype_name, access_to_variable_subtype_name) ;
```

6 Procedure `Free` has the following effect:

- 7 1. After executing `Free(X)`, the value of `X` is **null**.
- 8 2. `Free(X)`, when `X` is already equal to **null**, has no effect.
- 9/3 3. *{AI95-00416-01}* *{AI05-0107-1}* `Free(X)`, when `X` is not equal to **null** first performs finalization of the object designated by `X` (and any coextensions of the object — see 3.10.2), as described in 7.6.1. It then deallocates the storage occupied by the object designated by `X` (and any coextensions). If the storage pool is a user-defined object, then the storage is deallocated by calling `Deallocate` as described in 13.11. There is one exception: if the object being freed contains tasks, the object might not be deallocated.

9.a/3 **Ramification:** *{AI05-0107-1}* `Free` calls only the specified `Deallocate` procedure to do deallocation.

10/2 *{AI95-00416-01}* After `Free(X)`, the object designated by `X`, and any subcomponents (and coextensions) thereof, no longer exist; their storage can be reused for other purposes.

Bounded (Run-Time) Errors

11 It is a bounded error to free a discriminated, unterminated task object. The possible consequences are:

11.a **Reason:** This is an error because the task might refer to its discriminants, and the discriminants might be deallocated by freeing the task object.

- 12 • No exception is raised.
- 13 • `Program_Error` or `Tasking_Error` is raised at the point of the deallocation.
- 14 • `Program_Error` or `Tasking_Error` is raised in the task the next time it references any of the discriminants.

14.a **Implementation Note:** This last case presumes an implementation where the task references its discriminants indirectly, and the pointer is nulled out when the task object is deallocated.

15 In the first two cases, the storage for the discriminants (and for any enclosing object if it is designated by an access discriminant of the task) is not reclaimed prior to task termination.

15.a **Ramification:** The storage might never be reclaimed.

Erroneous Execution

16/3 *{AI05-0033-1}* *{AI05-0262-1}* Evaluating a name that denotes a nonexistent object, or a protected subprogram or subprogram renaming whose associated object (if any) is nonexistent, is erroneous. The execution of a call to an instance of `Unchecked_Deallocation` is erroneous if the object was created other than by an allocator for an access type whose pool is `Name'Storage_Pool`.

16.a/3 **Reason:** *{AI05-0033-1}* *{AI05-0262-1}* The part about a protected subprogram is intended to cover the case of an access-to-protected-subprogram where the associated object has been deallocated. The part about a subprogram renaming is intended to cover the case of a renaming of a prefixed view where the prefix object has been deallocated, or the case of a renaming of an entry or protected subprogram where the associated task or protected object has been deallocated.

16.b/3 **Ramification:** *{AI05-0157-1}* This text does not cover the case of a name that contains a null access value, as **null** does not denote an object (rather than denoting a nonexistent object).

Implementation Advice

- For a standard storage pool, Free should actually reclaim the storage. 17
- Implementation Advice:** For a standard storage pool, an instance of Unchecked_Deallocation should actually reclaim the storage. 17.a.1/2
- Ramification:** {AI95-00114-01} This is not a testable property, since we do not know how much storage is used by a given pool element, nor whether fragmentation can occur. 17.a/2
- {AI05-0157-1} A call on an instance of Unchecked_Deallocation with a nonnull access value should raise Program_Error if the actual access type of the instance is a type for which the Storage_Size has been specified to be zero or is defined by the language to be zero. 17.1/3
- Implementation Advice:** A call on an instance of Unchecked_Deallocation with a nonnull access value should raise Program_Error if the actual access type of the instance is a type for which the Storage_Size has been specified to be zero or is defined by the language to be zero. 17.a.1/3
- Discussion:** If the call is not illegal (as in a generic body), we recommend that it raise Program_Error. Since the execution of this call is erroneous (any allocator from the pool will have raised Storage_Error, so the nonnull access value must have been allocated from a different pool or be a stack-allocated object), we can't require any behavior — anything at all would be a legitimate implementation. 17.b

NOTES

- 30 The rules here that refer to Free apply to any instance of Unchecked_Deallocation. 18
- 31 Unchecked_Deallocation cannot be instantiated for an access-to-constant type. This is implied by the rules of 12.5.4. 19

Wording Changes from Ada 95

- {AI95-00416-01} The rules for coextensions are clarified (mainly by adding that term). In theory, this reflects no change from Ada 95 (coextensions existed in Ada 95, they just didn't have a name). 19.a/2

Wording Changes from Ada 2005

- {AI05-0033-1} **Correction:** Added a rule that using an access-to-protected-subprogram is erroneous if the associated object no longer exists. It is hard to imagine an alternative meaning here, and this has no effect on correct programs. 19.b/3
- {AI05-0107-1} **Correction:** Moved the requirements on an implementation-generated call to Deallocate to 13.11, in order to put all of the rules associated with implementation-generated calls to Allocate and Deallocate together. 19.c/3
- {AI05-0157-1} **Correction:** Added wording so that calling an instance of Unchecked_Deallocation is treated similarly to allocators for access types where allocators would be banned. 19.d/3

13.11.3 Default Storage Pools

This paragraph was deleted. {AI05-0229-1} 1/3

Syntax

- {AI05-0190-1} {AI05-0229-1} The form of a pragma Default_Storage_Pool is as follows: 2/3
- {AI05-0190-1} {AI05-0229-1} **pragma** Default_Storage_Pool (storage_pool_indicator); 3/3
- {AI05-0190-1} storage_pool_indicator ::= storage_pool_name | **null** 3.1/3
- {AI05-0190-1} A pragma Default_Storage_Pool is allowed immediately within the visible part of a package_specification, immediately within a declarative_part, or as a configuration pragma. 3.2/3

Name Resolution Rules

- {AI05-0190-1} The storage_pool_name is expected to be of type Root_Storage_Pool'Class. 3.3/3

Legality Rules

- {AI05-0190-1} {AI05-0229-1} The storage_pool_name shall denote a variable. 4/3
- {AI05-0190-1} If the pragma is used as a configuration pragma, the storage_pool_indicator shall be **null**, and it defines the default_pool to be **null** within all applicable compilation units (see 10.1.5), except 4.1/3

within the immediate scope of another pragma `Default_Storage_Pool`. Otherwise, [the pragma occurs immediately within a sequence of declarations, and] it defines the default pool within the immediate scope of the pragma to be either **null** or the pool denoted by the *storage_pool_name*, except within the immediate scope of a later pragma `Default_Storage_Pool`. [Thus, an inner pragma overrides an outer one.]

4.2/3 {AI05-0190-1} {AI05-0262-1} A pragma `Default_Storage_Pool` shall not be used as a configuration pragma that applies to a compilation unit that is within the immediate scope of another pragma `Default_Storage_Pool`.

4.a/3 **Reason:** This is to prevent confusion in cases like this:

```
4.b/3     package Parent is
           pragma Default_Storage_Pool(...);
           ...
         end Parent;
4.c/3     pragma Default_Storage_Pool(...); -- Illegal!
         package Parent.Child is
           ...
         end Parent.Child;
```

4.d/3 where the `Default_Storage_Pool` on `Parent.Child` would not (if it were legal) override the one in `Parent`.

Static Semantics

5/3 {AI05-0190-1} {AI05-0229-1} The language-defined aspect `Default_Storage_Pool` may be specified for a generic instance; it defines the default pool for access types within an instance. The expected type for the `Default_Storage_Pool` aspect is `Root_Storage_Pool'Class`. The **aspect_definition** must be a name that denotes a variable. This aspect overrides any `Default_Storage_Pool` pragma that might apply to the generic unit; if the aspect is not specified, the default pool of the instance is that defined for the generic unit.

5.a/3 **Aspect Description for `Default_Storage_Pool`:** Default storage pool for a generic instance.

6/3 {AI05-0190-1} {AI05-0229-1} For nonderived access types declared in places where the default pool is defined by the pragma or aspect, their `Storage_Pool` or `Storage_Size` attribute is determined as follows, unless `Storage_Pool` or `Storage_Size` is specified for the type:

- 6.1/3 • {AI05-0190-1} If the default pool is **null**, the `Storage_Size` attribute is defined by the language to be zero. [Therefore, an **allocator** for such a type is illegal.]
- 6.2/3 • {AI05-0190-1} If the default pool is nonnull, the `Storage_Pool` attribute is that pool.

6.3/3 {AI05-0190-1} [Otherwise, there is no default pool; the standard storage pool is used for the type as described in 13.11.]

6.a/3 **Ramification:** {AI05-0190-1} {AI05-0229-1} `Default_Storage_Pool` is the only way to specify the storage pool for an anonymous access type.

6.b/3 {AI05-0190-1} {AI05-0229-1} Note that coextensions should be allocated in the same pool (or on the stack) as the outer object (see 13.11); the `Storage_Pool` of the access discriminant (and hence the `Default_Storage_Pool`) is supposed to be ignored for coextensions. This matches the required finalization point for coextensions.

6.b.1/3 {AI05-0190-1} The default storage pool for an allocator that occurs within an instance of a generic is defined by the `Default_Storage_Pool` aspect of the instantiation (if specified), or by the `Default_Storage_Pool` pragma that applies to the generic; the `Default_Storage_Pool` pragma that applies to the instantiation is irrelevant.

6.b.2/3 {AI05-0190-1} It is possible to specify the `Default_Storage_Pool` aspect for an instantiation such that allocations will fail. For example, the generic unit might be expecting a pool that supports certain sizes and alignments, and the one on the instance might be more restrictive. It is the programmer's responsibility to get this right.

6.b.3/3 {AI05-0190-1} The semantics of the `Default_Storage_Pool` aspect are similar to passing a pool object as a generic formal, and putting pragma `Default_Storage_Pool` at the top of the generic's visible part, specifying that formal.

7/3 *This paragraph was deleted.* {AI05-0229-1}

Implementation Permissions

{AI05-0190-1} {AI05-0229-1} An object created by an allocator that is passed as the actual parameter to an access parameter may be allocated on the stack, and automatically reclaimed, regardless of the default pool.. 8/3

Discussion: {AI05-0190-1} This matches the required finalization point for such an allocated object. 8.a/3

NOTES

32 {AI05-0190-1} Default_Storage_Pool may be used with restrictions No_Coextensions and No_Access_Parameter_Allocators (see H.4) to ensure that all allocators use the default pool. 9/3

Wording Changes from Ada 83

This paragraph was deleted. {AI05-0229-1} 9.a/3

Incompatibilities With Ada 2005

{AI05-0229-1} Pragma Controlled has been dropped from Ada, as it has no effect in any known Ada implementations and it seems to promise capabilities not expected in Ada implementations. This is usually not an incompatibility, as the pragma merely becomes unrecognized (with a warning) and can be implemented as an implementation-defined pragma if desired. However, it is incompatible if it is (now) implemented as an implementation-defined pragma, someone used this pragma in a unit, and they also used restriction No_Implementation_Pragmas on that unit. In that case, the pragma would now violate the restriction; but use of this pragma (which does nothing) should be very rare, so this is not a significant issue. 9.b/3

Extensions to Ada 2005

{AI05-0190-1} The pragma Default_Storage_Pool is new. 9.c/3

Wording Changes from Ada 2005

{AI05-0229-1} The entire discussion of garbage collection (and especially that of controlled objects) is deleted. Ada 2012 provides subpools (see 13.11.4) for storage management of objects, including controlled objects, a mechanism which is much more predictable than garbage collection. Note that no version of Ada allows early finalization of controlled objects (other than via the use of Unchecked_Deallocation or Unchecked_Deallocate_Subpool), so that garbage collection of such objects would be ineffective in the standard mode anyway. 9.d/3

13.11.4 Storage Subpools

{AI05-0111-3} This subclause defines a package to support the partitioning of a storage pool into subpools. A subpool may be specified as the default to be used for allocation from the associated storage pool, or a particular subpool may be specified as part of an allocator (see 4.8). 1/3

Static Semantics

{AI05-0111-3} The following language-defined library package exists: 2/3

```
package System.Storage_Pools.Subpools is
  pragma Preelaborate (Subpools); 3/3
```

```
  type Root_Storage_Pool_With_Subpools is
    abstract new Root_Storage_Pool with private; 4/3
```

```
  type Root_Subpool is abstract tagged limited private; 5/3
```

```
  type Subpool_Handle is access all Root_Subpool'Class;
  for Subpool_Handle'Storage_Size use 0; 6/3
```

```
  function Create_Subpool (Pool : in out Root_Storage_Pool_With_Subpools)
    return not null Subpool_Handle is abstract; 7/3
```

{AI05-0252-1} -- The following operations are intended for pool implementers: 8/3

```
  function Pool_of_Subpool (Subpool : not null Subpool_Handle)
    return access Root_Storage_Pool_With_Subpools'Class; 9/3
```

```
  procedure Set_Pool_of_Subpool (
    Subpool : in not null Subpool_Handle;
    To : in out Root_Storage_Pool_With_Subpools'Class); 10/3
```

```

11/3   procedure Allocate_From_Subpool (
        Pool : in out Root_Storage_Pool_With_Subpools;
        Storage_Address : out Address;
        Size_In_Storage_Elements : in Storage_Elements.Storage_Count;
        Alignment : in Storage_Elements.Storage_Count;
        Subpool : in not null Subpool_Handle) is abstract
        with Pre'Class => Pool_of_Subpool(Subpool) = Pool'Access;

12/3   procedure Deallocate_Subpool (
        Pool : in out Root_Storage_Pool_With_Subpools;
        Subpool : in out Subpool_Handle) is abstract
        with Pre'Class => Pool_of_Subpool(Subpool) = Pool'Access;

13/3   {AI05-0298-1}   function Default_Subpool_for_Pool (
        Pool : in out Root_Storage_Pool_With_Subpools)
        return not null Subpool_Handle;

14/3   overriding
procedure Allocate (
        Pool : in out Root_Storage_Pool_With_Subpools;
        Storage_Address : out Address;
        Size_In_Storage_Elements : in Storage_Elements.Storage_Count;
        Alignment : in Storage_Elements.Storage_Count);

15/3   overriding
procedure Deallocate (
        Pool : in out Root_Storage_Pool_With_Subpools;
        Storage_Address : in Address;
        Size_In_Storage_Elements : in Storage_Elements.Storage_Count;
        Alignment : in Storage_Elements.Storage_Count) is null;

16/3   {AI05-0298-1}   overriding
function Storage_Size (Pool : Root_Storage_Pool_With_Subpools)
        return Storage_Elements.Storage_Count
        is (Storage_Elements.Storage_Count'Last);

17/3   private
        ... -- not specified by the language
    end System.Storage_Pools.Subpools;

```

18/3 {AI05-0111-3} A *subpool* is a separately reclaimable portion of a storage pool, identified by an object of type `Subpool_Handle` (a *subpool handle*). A subpool handle also identifies the enclosing storage pool, a *storage pool that supports subpools*, which is a storage pool whose type is descended from `Root_Storage_Pool_With_Subpools`. A subpool is created by calling `Create_Subpool` or a similar constructor; the constructor returns the subpool handle.

19/3 {AI05-0111-3} {AI05-0269-1} A *subpool object* is an object of a type descended from `Root_Subpool`. [Typically, subpool objects are managed by the containing storage pool; only the handles need be exposed to clients of the storage pool. Subpool objects are designated by subpool handles, and are the run-time representation of a subpool.]

19.a/3 **Proof:** We know that subpool handles designate subpool objects because the declaration of `Subpool_Handle` says so.

20/3 {AI05-0111-3} Each subpool *belongs* to a single storage pool [(which will always be a pool that supports subpools)]. An access to the pool that a subpool belongs to can be obtained by calling `Pool_of_Subpool` with the subpool handle. `Set_Pool_of_Subpool` causes the subpool of the subpool handle to belong to the given pool; this is intended to be called from subpool constructors like `Create_Subpool`.] `Set_Pool_of_Subpool` propagates `Program_Error` if the subpool already belongs to a pool.

20.a/3 **Discussion:** `Pool_of_Subpool` and `Set_Pool_of_Subpool` are provided by the Ada implementation and typically will not be overridden by the pool implementer.

21/3 {AI05-0111-3} When an *allocator* for a type whose storage pool supports subpools is evaluated, a call is made on `Allocate_From_Subpool` passing in a `Subpool_Handle`, in addition to the parameters as defined for calls on `Allocate` (see 13.11). The subpool designated by the *subpool_handle_name* is used, if

specified in an allocator. Otherwise, `Default_Subpool_for_Pool` of the `Pool` is used to provide a subpool handle. All requirements on the `Allocate` procedure also apply to `Allocate_from_Subpool`.

Discussion: `Deallocate_Subpool` is expected to do whatever is needed to deallocate all of the objects contained in the subpool; it is called from `Unchecked_Deallocate_Subpool` (see 13.11.5). 21.a/3

Typically, the pool implementer will not override `Allocate`. In the canonical definition of the language, it will never be called for a pool that supports subpools (there is an Implementation Permission below that allows it to be called in certain rare cases). 21.b/3

Legality Rules

{AI05-0111-3} If a storage pool that supports subpools is specified as the `Storage_Pool` for an access type, the access type is called a *subpool access type*. A subpool access type shall be a pool-specific access type. 22/3

{AI05-0111-3} {AI05-0252-1} The accessibility level of a subpool access type shall not be statically deeper than that of the storage pool object. If the specified storage pool object is a storage pool that supports subpools, then the name that denotes the object shall not denote part of a formal parameter, nor shall it denote part of a dereference of a value of a non-library-level general access type. In addition to the places where Legality Rules normally apply (see 12.3), these rules also apply in the private part of an instance of a generic unit. 23/3

Dynamic Semantics

{AI05-0111-3} {AI05-0252-1} When an access type with a specified storage pool is frozen (see 13.14), if the tag of the storage pool object identifies a storage pool that supports subpools, the following checks are made: 24/3

- the name used to specify the storage pool object does not denote part of a formal parameter nor part of a dereference of a value of a non-library-level general access type; and 25/3
- the accessibility level of the access type is not deeper than that of the storage pool object. 26/3

{AI05-0252-1} `Program_Error` is raised if either of these checks fail. 27/3

Reason: This check (and its static counterpart) ensures that the type of the allocated objects exists at least as long as the storage pool object, so that the subpools are finalized (which finalizes any remaining allocated objects) before the type of the objects ceases to exist. The access type itself (and the associated collection) will cease to exist before the storage pool ceases to exist. 27.a/3

We also disallow the use of formal parameters and dereferences of non-library-level general access types when specifying a storage pool object if it supports subpools, because the "apparent" accessibility level is potentially deeper than that of the underlying object. Neither of these cases is very likely to occur in practice. 27.b/3

{AI05-0111-3} A call to `Subpools.Allocate(P, Addr, Size, Align)` does the following: 28/3

```
Allocate_From_Subpool
  (Root_Storage_Pool_With_Subpools'Class(P) ,
   Addr, Size, Align,
   Subpool => Default_Subpool_for_Pool
             (Root_Storage_Pool_With_Subpools'Class(P))); 29/3
```

{AI05-0111-3} An allocator that allocates in a subpool raises `Program_Error` if the allocated object has task parts. 30/3

Reason: This is to ease implementation. We envision relaxing this restriction in a future version of Ada, once implementation experience has been gained. At this time, we are unable to come up with a set of rules for task termination that is both useful, and surely feasible to implement. 30.a/3

{AI05-0111-3} Unless overridden, `Default_Subpool_for_Pool` propagates `Program_Error`. 31/3

Implementation Permissions

32/3 {AI05-0111-3} When an allocator for a type whose storage pool is of type `Root_Storage_Pool`'Class is evaluated, but supports subpools, the implementation may call `Allocate` rather than `Allocate_From_Subpool`. [This will have the same effect, so long as `Allocate` has not been overridden.]

32.a/3 **Reason:** This ensures either of two implementation models are possible for an allocator with no `subpool_specification`. Note that the "supports subpools" property is not known at compile time for a pool of the class-wide type.

32.b/3 • The implementation can dispatch to `Storage_Pools.Allocate`. If the pool supports subpools, this will call `Allocate_From_Subpool` with the default subpool so long as `Allocate` has not been overridden.

32.c/3 • The implementation can declare `Allocate_From_Subpool` as a primitive of `Root_Storage_Pool` in the private part of `Storage_Pools`. This means that the `Allocate_From_Subpool` for `Root_Storage_Pool_With_Subpools` overrides that private one. The implementation can thus call the private one, which will call `Allocate` for non-subpool-supporting pools. The effect of this implementation does not change if `Allocate` is overridden for a pool that supports subpools.

NOTES

33/3 33 {AI05-0111-3} A user-defined storage pool type that supports subpools can be implemented by extending the `Root_Storage_Pool_With_Subpools` type, and overriding the primitive subprograms `Create_Subpool`, `Allocate_From_Subpool`, and `Deallocate_Subpool`. `Create_Subpool` should call `Set_Pool_Of_Subpool` before returning the subpool handle. To make use of such a pool, a user would declare an object of the type extension, use it to define the `Storage_Pool` attribute of one or more access types, and then call `Create_Subpool` to obtain subpool handles associated with the pool.

34/3 34 {AI05-0111-3} A user-defined storage pool type that supports subpools may define additional subpool constructors similar to `Create_Subpool` (these typically will have additional parameters).

35/3 35 {AI05-0111-3} The pool implementor should override `Default_Subpool_For_Pool` if the pool is to support a default subpool for the pool. The implementor can override `Deallocate` if individual object reclamation is to be supported, and can override `Storage_Size` if there is some limit on the total size of the storage pool. The implementor can override `Initialize` and `Finalize` if there is any need for nontrivial initialization and finalization for the pool as a whole. For example, `Finalize` might reclaim blocks of storage that are allocated over and above the space occupied by the pool object itself. The pool implementor may extend the `Root_Subpool` type as necessary to carry additional information with each subpool provided by `Create_Subpool`.

Extensions to Ada 2005

35.a/3 {AI05-0111-3} {AI05-0252-1} Subpools and the package `System.Storage_Pools.Subpools` are new.

13.11.5 Subpool Reclamation

1/3 {AI05-0111-3} A subpool may be explicitly deallocated using `Unchecked_Deallocate_Subpool`.

Static Semantics

2/3 {AI05-0111-3} The following language-defined library procedure exists:

```
3/3   with System.Storage_Pools.Subpools;
      procedure Ada.Unchecked_Deallocate_Subpool
         (Subpool : in out System.Storage_Pools.Subpools.Subpool_Handle);
```

4/3 {AI05-0111-3} If `Subpool` is **null**, a call on `Unchecked_Deallocate_Subpool` has no effect. Otherwise, the subpool is finalized, and `Subpool` is set to **null**.

5/3 {AI05-0111-3} Finalization of a subpool has the following effects:

- 6/3 • The subpool no longer belongs to any pool;
- 7/3 • Any of the objects allocated from the subpool that still exist are finalized in an arbitrary order;
- 8/3 • The following [dispatching] call is then made:

```
9/3   Deallocate_Subpool(Pool_of_Subpool(Subpool).all, Subpool);
```

10/3 {AI05-0111-3} Finalization of a `Root_Storage_Pool_With_Subpools` object finalizes all subpools that belong to that pool that have not yet been finalized.

Discussion: There is no need to call `Unchecked_Deallocation` on an object allocated in a subpool. Such objects are deallocated all at once, when `Unchecked_Deallocate_Subpool` is called. 10.a/3

If `Unchecked_Deallocation` is called, the object is finalized, and then `Deallocate` is called on the Pool, which typically will do nothing. If it wants to free memory, it will need some way to get from the address of the object to the subpool. 10.b/3

There is no `Deallocate_From_Subpool`. There is no efficient way for the implementation to determine the subpool for an arbitrary object, and if the pool implementer can determinate that, they can use that as part of the implementation of `Deallocate`. 10.c/3

If `Unchecked_Deallocation` is not called (the usual case), the object will be finalized when `Unchecked_Deallocate_Subpool` is called. 10.d/3

If that's never called, then the object will be finalized when the `Pool_With_Subpools` is finalized (by permission — it might happen when the collection of the access type is finalized). 10.e/3

Extensions to Ada 2005

{AI05-0111-3} `Unchecked_Deallocate_Subpool` is new. 10.f/3

13.11.6 Storage Subpool Example

Examples

{AI05-0111-3} The following example is a simple but complete implementation of the classic Mark/Release pool using subpools: 1/3

```
with System.Storage_Pools.Subpools;
with System.Storage_Elements;
with Ada.Unchecked_Deallocate_Subpool;
package MR_Pool is
    use System.Storage_Pools;
    -- For uses of Subpools.
    use System.Storage_Elements;
    -- For uses of Storage_Count and Storage_Array.
    -- Mark and Release work in a stack fashion, and allocations are not allowed
    -- from a subpool other than the one at the top of the stack. This is also
    -- the default pool.
    subtype Subpool_Handle is Subpools.Subpool_Handle;
    type Mark_Release_Pool_Type (Pool_Size : Storage_Count) is new
        Subpools.Root_Storage_Pool_With_Subpools with private;
    function Mark (Pool : in out Mark_Release_Pool_Type)
        return not null Subpool_Handle;
    procedure Release (Subpool : in out Subpool_Handle) renames
        Ada.Unchecked_Deallocate_Subpool;
private
    type MR_Subpool is new Subpools.Root_Subpool with record
        Start : Storage_Count;
    end record;
    subtype Subpool_Indexes is Positive range 1 .. 10;
    type Subpool_Array is array (Subpool_Indexes) of aliased MR_Subpool;
    {AI05-0298-1} type Mark_Release_Pool_Type (Pool_Size : Storage_Count) is new
        Subpools.Root_Storage_Pool_With_Subpools with record
            Storage : Storage_Array (0 .. Pool_Size-1);
            Next_Allocation : Storage_Count := 0;
            Markers : Subpool_Array;
            Current_Pool : Subpool_Indexes := 1;
        end record;
    {AI05-0298-1} overriding
    function Create_Subpool (Pool : in out Mark_Release_Pool_Type)
        return not null Subpool_Handle;
```

```

13/3     function Mark (Pool : in out Mark_Release_Pool_Type)
         return not null Subpool_Handle renames Create_Subpool;
14/3     overriding
         procedure Allocate_From_Subpool (
           Pool : in out Mark_Release_Pool_Type;
           Storage_Address : out System.Address;
           Size_In_Storage_Elements : in Storage_Count;
           Alignment : in Storage_Count;
           Subpool : not null Subpool_Handle);
15/3     overriding
         procedure Deallocate_Subpool (
           Pool : in out Mark_Release_Pool_Type;
           Subpool : in out Subpool_Handle);
16/3     {AI05-0298-1} overriding
         function Default_Subpool_for_Pool (Pool : in out Mark_Release_Pool_Type)
         return not null Subpool_Handle;
17/3     overriding
         procedure Initialize (Pool : in out Mark_Release_Pool_Type);
18/3     -- We don't need Finalize.
19/3     end MR_Pool;
20/3     package body MR_Pool is
21/3     {AI05-0298-1} use type Subpool_Handle;
22/3     {AI05-0298-1} procedure Initialize (Pool : in out Mark_Release_Pool_Type) is
         -- Initialize the first default subpool.
         begin
           Pool.Markers(1).Start := 1;
           Subpools.Set_Pool_of_Subpool
             (Pool.Markers(1)'Unchecked_Access, Pool);
         end Initialize;
23/3     function Create_Subpool (Pool : in out Mark_Release_Pool_Type)
         return not null Subpool_Handle is
         -- Mark the current allocation location.
         begin
           if Pool.Current_Pool = Subpool_Indexes'Last then
             raise Storage_Error; -- No more subpools.
           end if;
           Pool.Current_Pool := Pool.Current_Pool + 1; -- Move to the next subpool
24/3     {AI05-0298-1} return Result : constant not null Subpool_Handle :=
           Pool.Markers(Pool.Current_Pool)'Unchecked_Access
         do
           Pool.Markers(Pool.Current_Pool).Start := Pool.Next_Allocation;
           Subpools.Set_Pool_of_Subpool (Result, Pool);
         end return;
         end Create_Subpool;
25/3     {AI05-0298-1} procedure Deallocate_Subpool (
           Pool : in out Mark_Release_Pool_Type;
           Subpool : in out Subpool_Handle) is
         begin
           if Subpool /= Pool.Markers(Pool.Current_Pool)'Unchecked_Access then
             raise Program_Error; -- Only the last marked subpool can be released.
           end if;
           if Pool.Current_Pool /= 1 then
             Pool.Next_Allocation := Pool.Markers(Pool.Current_Pool).Start;
             Pool.Current_Pool := Pool.Current_Pool - 1; -- Move to the previous subpool
           else -- Reinitialize the default subpool:
             Pool.Next_Allocation := 1;
             Subpools.Set_Pool_of_Subpool
               (Pool.Markers(1)'Unchecked_Access, Pool);
           end if;
         end Deallocate_Subpool;

```

```

{AI05-0298-1}      function Default_Subpool_for_Pool (Pool : in out           26/3
Mark_Release_Pool_Type)
    return not null Subpool_Handle is
    begin
        return Pool.Markers (Pool.Current_Pool) 'Unchecked_Access;
    end Default_Subpool_for_Pool;

procedure Allocate_From_Subpool (           27/3
    Pool : in out Mark_Release_Pool_Type;
    Storage_Address : out System.Address;
    Size_In_Storage_Elements : in Storage_Count;
    Alignment : in Storage_Count;
    Subpool : not null Subpool_Handle) is
    begin
        if Subpool /= Pool.Markers (Pool.Current_Pool) 'Unchecked_Access then
            raise Program_Error; -- Only the last marked subpool can be used for allocations.
        end if;

        -- Correct the alignment if necessary:
        Pool.Next_Allocation := Pool.Next_Allocation +           28/3
            ((-Pool.Next_Allocation) mod Alignment);
        if Pool.Next_Allocation + Size_In_Storage_Elements >
            Pool.Pool_Size then
            raise Storage_Error; -- Out of space.
        end if;
        Storage_Address := Pool.Storage (Pool.Next_Allocation) 'Address;
        Pool.Next_Allocation :=
            Pool.Next_Allocation + Size_In_Storage_Elements;
    end Allocate_From_Subpool;
end MR_Pool;                               29/3

```

Wording Changes from Ada 2005

{AI05-0111-3} This example of subpools is new. 29.a/3

13.12 Pragma Restrictions and Pragma Profile

{AI05-0246-1} [A pragma Restrictions expresses the user's intent to abide by certain restrictions. A pragma Profile expresses the user's intent to abide by a set of Restrictions or other specified run-time policies. These may facilitate the construction of simpler run-time environments.] 1/3

Syntax

The form of a pragma Restrictions is as follows: 2

```

pragma Restrictions(restriction{, restriction});           3
{AI95-00381-01} restriction ::= restriction_identifier     4/2
    | restriction_parameter_identifier => restriction_parameter_argument
{AI95-00381-01} restriction_parameter_argument ::= name | expression           4.1/2

```

Name Resolution Rules

Unless otherwise specified for a particular restriction, the expression is expected to be of any integer type. 5

Legality Rules

Unless otherwise specified for a particular restriction, the expression shall be static, and its value shall be nonnegative. 6

This paragraph was deleted. 7.a/3

Paragraph 7 was deleted.

Post-Compilation Rules

- 8.3/3 {AI05-0013-1} A pragma Restrictions is a configuration pragma. If a pragma Restrictions applies to any compilation unit included in the partition, this may impose either (or both) of two kinds of requirements, as specified for the particular restriction:
- 8.1/3 • {AI05-0013-1} A restriction may impose requirements on some or all of the units comprising the partition. Unless otherwise specified for a particular restriction, such a requirement applies to all of the units comprising the partition and is enforced via a post-compilation check.
- 8.2/3 • {AI05-0013-1} A restriction may impose requirements on the run-time behavior of the program, as indicated by the specification of run-time behavior associated with a violation of the requirement.
- 8.a.1/3 **Ramification:** In this latter case, there is no post-compilation check needed for the requirement.
- 8.3/1 {8652/0042} {AI95-00130-01} For the purpose of checking whether a partition contains constructs that violate any restriction (unless specified otherwise for a particular restriction):
- 8.4/1 • {8652/0042} {AI95-00130-01} Generic instances are logically expanded at the point of instantiation;
- 8.5/1 • {8652/0042} {AI95-00130-01} If an object of a type is declared or allocated and not explicitly initialized, then all expressions appearing in the definition for the type and any of its ancestors are presumed to be used;
- 8.6/1 • {8652/0042} {AI95-00130-01} A `default_expression` for a formal parameter or a generic formal object is considered to be used if and only if the corresponding actual parameter is not provided in a given call or instantiation.

Implementation Permissions

- 8.7/3 {AI05-0269-1} An implementation may provide implementation-defined restrictions; the identifier for an implementation-defined restriction shall differ from those of the language-defined restrictions.
- 8.a.2/3 **Implementation defined:** Implementation-defined restrictions allowed in a pragma Restrictions.
- 9 An implementation may place limitations on the values of the expression that are supported, and limitations on the supported combinations of restrictions. The consequences of violating such limitations are implementation defined.
- 9.a **Implementation defined:** The consequences of violating limitations on Restrictions pragmas.
- 9.b **Ramification:** Such limitations may be enforced at compile time or at run time. Alternatively, the implementation is allowed to declare violations of the restrictions to be erroneous, and not enforce them at all.
- 9.1/1 {8652/0042} {AI95-00130-01} An implementation is permitted to omit restriction checks for code that is recognized at compile time to be unreachable and for which no code is generated.
- 9.2/1 {8652/0043} {AI95-00190-01} Whenever enforcement of a restriction is not required prior to execution, an implementation may nevertheless enforce the restriction prior to execution of a partition to which the restriction applies, provided that every execution of the partition would violate the restriction.

Syntax

- 10/3 {AI95-00249-01} {AI05-0246-1} The form of a pragma Profile is as follows:
- 11/3 **pragma** Profile (*profile_identifier* {, *profile_pragma_argument_association*});

Legality Rules

- 12/3 {AI95-00249-01} {AI05-0246-1} The *profile_identifier* shall be the name of a usage profile. The semantics of any *profile_pragma_argument_associations* are defined by the usage profile specified by the *profile_identifier*.

Static Semantics

{AI95-00249-01} {AI05-0246-1} A profile is equivalent to the set of configuration pragmas that is defined for each usage profile. 13/3

Post-Compilation Rules

{AI95-00249-01} A pragma Profile is a configuration pragma. There may be more than one pragma Profile for a partition. 14/3

Implementation Permissions

{AI05-0269-1} An implementation may provide implementation-defined usage profiles; the identifier for an implementation-defined usage profile shall differ from those of the language-defined usage profiles. 15/3

Implementation defined: Implementation-defined usage profiles allowed in a pragma Profile. 15.a.1/3

NOTES

36 {AI95-00347-01} Restrictions intended to facilitate the construction of efficient tasking run-time systems are defined in D.7. Restrictions intended for use when constructing high integrity systems are defined in H.4. 16/2

37 An implementation has to enforce the restrictions in cases where enforcement is required, even if it chooses not to take advantage of the restrictions in terms of efficiency. 17

Discussion: It is not the intent that an implementation will support a different run-time system for every possible combination of restrictions. An implementation might support only two run-time systems, and document a set of restrictions that is sufficient to allow use of the more efficient and safe one. 17.a

Extensions to Ada 83

Pragma Restrictions is new to Ada 95. 17.b

Extensions to Ada 95

{AI95-00249-01} {AI05-0246-1} Pragma Profile is new; it was moved here by Ada 2012 and renamed to a "usage profile" but was otherwise unchanged. 17.c/3

Wording Changes from Ada 95

{8652/0042} {AI95-00130-01} **Corrigendum:** Corrected the wording so that restrictions are checked inside of generic instantiations and in default expressions. Since not making these checks would violate the purpose of restrictions, we are not documenting this as an incompatibility. 17.d/2

{8652/0043} {AI95-00190-01} **Corrigendum:** Added a permission that restrictions can be enforced at compile-time. While this is technically incompatible, documenting it as such would be unnecessarily alarming - there should not be any programs depending on the runtime failure of restrictions. 17.e/2

{AI95-00381-01} The syntax of a `restriction_parameter_argument` has been defined to better support restriction `No_Dependence` (see 13.12.1). 17.f/2

Wording Changes from Ada 2005

{AI05-0013-1} **Correction:** When restrictions are checked has been clarified. 17.g/3

13.12.1 Language-Defined Restrictions and Profiles

Static Semantics

{AI95-00257-01} The following `restriction_identifiers` are language defined (additional restrictions are defined in the Specialized Needs Annexes): 1/2

{AI05-0241-1} `No_Implementation_Aspect_Specifications` 1.1/3
 There are no implementation-defined aspects specified by an `aspect_specification`. This restriction applies only to the current compilation or environment, not the entire partition.

- 1.a/3 **Discussion:** *{AI05-0241-1}* This restriction (as well as others below) applies only to the current compilation, because it is likely that the runtime (and possibly user-written low-level code) will need to use implementation-defined aspects. But a partition-wide restriction applies everywhere, including the runtime.
- 2/2 *{AI95-00257-01}* `No_Implementation_Attributes`
 There are no implementation-defined attributes. This restriction applies only to the current compilation or environment, not the entire partition.
- 2.1/3 *{AI05-0246-1}* *{AI05-0269-1}* `No_Implementation_Identifiers`
 There are no usage names that denote declarations with implementation-defined identifiers that occur within language-defined packages or instances of language-defined generic packages. Such identifiers can arise as follows:
- 2.2/3 • The following language-defined packages and generic packages allow implementation-defined identifiers:
- 2.3/3 • package `System` (see 13.7);
- 2.4/3 • package `Standard` (see A.1);
- 2.5/3 • package `Ada.Command_Line` (see A.15);
- 2.6/3 • package `Interfaces.C` (see B.3);
- 2.7/3 • package `Interfaces.C.Strings` (see B.3.1);
- 2.8/3 • package `Interfaces.C.Pointers` (see B.3.2);
- 2.9/3 • package `Interfaces.COBOL` (see B.4);
- 2.10/3 • package `Interfaces.Fortran` (see B.5);
- 2.11/3 • The following language-defined packages contain only implementation-defined identifiers:
- 2.12/3 • package `System.Machine_Code` (see 13.8);
- 2.13/3 • package `Ada.Directories.Information` (see A.16);
- 2.14/3 • nested `Implementation` packages of the `Queue` containers (see A.18.28-31);
- 2.15/3 • package `Interfaces` (see B.2);
- 2.16/3 • package `Ada.Interrupts.Names` (see C.3.2).
- 2.17/3 For package `Standard`, `Standard.Long_Integer` and `Standard.Long_Float` are considered language-defined identifiers, but identifiers such as `Standard.Short_Short_Integer` are considered implementation-defined.
- 2.18/3 This restriction applies only to the current compilation or environment, not the entire partition.
- 3/2 *{AI95-00257-01}* `No_Implementation_Pragmas`
 There are no implementation-defined pragmas or pragma arguments. This restriction applies only to the current compilation or environment, not the entire partition.
- 3.1/3 *{AI05-0242-1}* `No_Implementation_Units`
 There is no mention in the `context_clause` of any implementation-defined descendants of packages `Ada`, `Interfaces`, or `System`. This restriction applies only to the current compilation or environment, not the entire partition.
- 4/3 *{AI95-00368-01}* *{AI05-0229-1}* `No_Obsolescent_Features`
 There is no use of language features defined in Annex J. It is implementation defined whether uses of the renamings of J.1 and of the pragmas of J.15 are detected by this restriction. This restriction applies only to the current compilation or environment, not the entire partition.
- 4.a/2 **Reason:** A user could compile a rename like

<pre>with Ada.Text_IO; package Text_IO renames Ada.Text_IO;</pre>	4.b/2
Such a rename must not be disallowed by this restriction, nor should the compilation of such a rename be restricted by an implementation. Many implementations implement the renames of J.1 by compiling them normally; we do not want to require implementations to use a special mechanism to implement these renames.	4.c/2
{AI05-0229-1} The pragmas have the same functionality as the corresponding aspect (unlike the typical obsolescent feature), and rejecting them could be a significant portability problem for existing code.	4.d/3
{AI95-00381-01} {AI05-0241-1} The following <i>restriction_parameter_identifiers</i> are language defined:	5/3
{AI95-00381-01} No_Dependence Specifies a library unit on which there are no semantic dependences.	6/2
{AI05-0241-1} No_Specification_of_Aspect Identifies an aspect for which no <i>aspect_specification</i> , <i>attribute_definition_clause</i> , or <i>pragma</i> is given.	6.1/3
{AI05-0272-1} No_Use_Of_Attribute Identifies an attribute for which no <i>attribute_reference</i> or <i>attribute_definition_clause</i> is given.	6.2/3
{AI05-0272-1} No_Use_Of_Pragma Identifies a <i>pragma</i> which is not to be used.	6.3/3
<i>Legality Rules</i>	
{AI95-00381-01} The <i>restriction_parameter_argument</i> of a No_Dependence restriction shall be a name; the name shall have the form of a full expanded name of a library unit, but need not denote a unit present in the environment.	7/2
Ramification: This name is not resolved.	7.a/2
{AI05-0241-1} The <i>restriction_parameter_argument</i> of a No_Specification_of_Aspect restriction shall be an identifier; this is an identifier specific to a pragma (see 2.8) and does not denote any declaration.	7.1/3
Ramification: This <i>restriction_parameter_argument</i> is not resolved as it is an identifier specific to a pragma. As for No_Dependence, there is no check that the aspect identifier is meaningful; it might refer to an implementation-defined aspect on one implementation, but nothing at all on another implementation.	7.b/3
{AI05-0272-1} The <i>restriction_parameter_argument</i> of a No_Use_Of_Attribute restriction shall be an identifier or one of the reserved words Access, Delta, Digits, Mod, or Range; this is an identifier specific to a pragma.	7.2/3
Ramification: This <i>restriction_parameter_argument</i> is not resolved as it is an identifier specific to a pragma. There is no check that the attribute identifier refers to a known <i>attribute_designator</i> ; it might refer to an implementation-defined attribute on one implementation, but nothing at all on another implementation.	7.c/3
{AI05-0272-1} The <i>restriction_parameter_argument</i> of a No_Use_Of_Pragma restriction shall be an identifier or the reserved word Interface; this is an identifier specific to a pragma.	7.3/3
Ramification: This <i>restriction_parameter_argument</i> is not resolved as it is an identifier specific to a pragma. There is no check that the pragma identifier refers to a known <i>pragma</i> ; it might refer to an implementation-defined pragma on one implementation, but nothing at all on another implementation.	7.d/3
<i>Post-Compilation Rules</i>	
{AI95-00381-01} {AI05-0241-1} No compilation unit included in the partition shall depend semantically on the library unit identified by the name of a No_Dependence restriction.	8/3
Ramification: There is no requirement that the library unit actually exist. One possible use of the pragma is to prevent the use of implementation-defined units; when the program is ported to a different compiler, it is perfectly reasonable that no unit with the name exist.	8.a/2

Static Semantics

- 9/3 {AI05-0246-1} The following *profile_identifier* is language defined:
- 10/3 {AI05-0246-1} No_Implementation_Extensions
- 11/3 {AI05-0246-1} For usage profile No_Implementation_Extensions, there shall be no *profile_pragma_argument_associations*.
- 12/3 {AI05-0246-1} The No_Implementation_Extensions usage profile is equivalent to the following restrictions:
- 13/3 No_Implementation_Aspect_Specifications,
No_Implementation_Attributes,
No_Implementation_Identifiers,
No_Implementation_Pragmas,
No_Implementation_Units.

Extensions to Ada 95

- 13.a/2 {AI95-00257-01} {AI95-00368-01} Restrictions No_Implementation_Attributes, No_Implementation_Pragmas, and No_Obsolescent_Features are new.
- 13.b/2 {AI95-00381-01} Restriction No_Dependence is new.

Extensions to Ada 2005

- 13.c/3 {AI05-0241-1} {AI05-0242-1} {AI05-0246-1} {AI05-0272-1} Restrictions No_Implementation_Aspect_Specifications, No_Implementation_Identifiers, No_Implementation_Units, No_Specification_of_Aspect, No_Use_of_Attribute, and No_Use_of_Pragma are new.
- 13.d/3 {AI05-0246-1} Profile No_Implementation_Extensions is new.

13.13 Streams

- 1 A *stream* is a sequence of elements comprising values from possibly different types and allowing sequential access to these values. A *stream type* is a type in the class whose root type is Streams.Root_Stream_Type. A stream type may be implemented in various ways, such as an external sequential file, an internal buffer, or a network channel.
- 1.a **Discussion:** A stream element will often be the same size as a storage element, but that is not required.
- 1.a.1/3 **Glossary entry:** A stream is a sequence of elements that can be used, along with the stream-oriented attributes, to support marshalling and unmarshalling of values of most types.

Extensions to Ada 83

- 1.b Streams are new in Ada 95.

13.13.1 The Package Streams

Static Semantics

- 1 The abstract type Root_Stream_Type is the root type of the class of stream types. The types in this class represent different kinds of streams. A new stream type is defined by extending the root type (or some other stream type), overriding the Read and Write operations, and optionally defining additional primitive subprograms, according to the requirements of the particular kind of stream. The predefined stream-oriented attributes like T'Read and T'Write make dispatching calls on the Read and Write procedures of the Root_Stream_Type. (User-defined T'Read and T'Write attributes can also make such calls, or can call the Read and Write attributes of other types.)
- 2 **package** Ada.Streams **is**
 pragma Pure (Streams);

```

{AI95-00161-01}      type Root_Stream_Type is abstract tagged limited private;      3/2
                    pragma Preelaborable_Initialization(Root_Stream_Type);

{8652/0044} {AI95-00181-01}      type Stream_Element is mod implementation-defined;  4/1
                    type Stream_Element_Offset is range implementation-defined;
                    subtype Stream_Element_Count is
                        Stream_Element_Offset range 0..Stream_Element_Offset'Last;
                    type Stream_Element_Array is
                        array(Stream_Element_Offset range <>) of aliased Stream_Element;

                    procedure Read(                                              5
                        Stream : in out Root_Stream_Type;
                        Item   : out Stream_Element_Array;
                        Last   : out Stream_Element_Offset) is abstract;

                    procedure Write(                                           6
                        Stream : in out Root_Stream_Type;
                        Item   : in Stream_Element_Array) is abstract;

private
    ... -- not specified by the language                                       7
end Ada.Streams;

```

{AI95-00227-01} The Read operation transfers stream elements from the specified stream to fill the array Item. Elements are transferred until Item'Length elements have been transferred, or until the end of the stream is reached. If any elements are transferred, the index of the last stream element transferred is returned in Last. Otherwise, Item'First - 1 is returned in Last. Last is less than Item'Last only if the end of the stream is reached. 8/2

The Write operation appends Item to the specified stream. 9

Discussion: {AI95-00114-01} The index subtype of Stream_Element_Array is Stream_Element_Offset because we wish to allow maximum flexibility. Most Stream_Element_Arrays will probably have a lower bound of 0 or 1, but other lower bounds, including negative ones, make sense in some situations. 9.a/2

{AI95-00114-01} {AI05-0005-1} Note that there are some language-defined subprograms that fill part of a Stream_Element_Array, and return the index of the last element filled as a Stream_Element_Offset. The Read procedures declared here, Streams.Stream_IO (see A.12.1), and System.RPC (see E.5) behave in this manner. These will raise Constraint_Error if the resulting Last value is not in Stream_Element_Offset. This implies that the Stream_Element_Array passed to these subprograms should not have a lower bound of Stream_Element_Offset'First, because then a read of 0 elements would always raise Constraint_Error. A better choice of lower bound is 0 or 1. 9.b/3

Implementation Permissions

{8652/0044} {AI95-00181-01} If Stream_Element'Size is not a multiple of System.Storage_Unit, then the components of Stream_Element_Array need not be aliased. 9.1/1

Ramification: {AI95-00114-01} If the Stream_Element'Size is less than the size of System.Storage_Unit, then components of Stream_Element_Array need not be aliased. This is necessary as the components of type Stream_Element size might not be addressable on the target architecture. 9.b.1/2

NOTES

38 See A.12.1, “The Package Streams.Stream_IO” for an example of extending type Root_Stream_Type. 10

39 {AI95-00227-01} If the end of stream has been reached, and Item'First is Stream_Element_Offset'First, Read will raise Constraint_Error. 11/2

Ramification: Thus, Stream_Element_Arrays should start at 0 or 1, not Stream_Element_Offset'First. 11.a/2

Extensions to Ada 95

{AI95-00161-01} **Amendment Correction:** Added pragma Preelaborable_Initialization to type Root_Stream_Type. 11.b/2

Wording Changes from Ada 95

{8652/0044} {AI95-00181-01} **Corrigendum:** Stream elements are aliased presuming that makes sense. 11.c/2

{AI95-00227-01} Fixed the wording for Read to properly define the result in Last when no stream elements are transferred. 11.d/2

13.13.2 Stream-Oriented Attributes

1/3 {8652/0009} {AI95-00137-01} {AI05-0183-1} The type-related operational attributes Write, Read, Output, and Input convert values to a stream of elements and reconstruct values from a stream.

Static Semantics

1.1/2 {AI95-00270-01} For every subtype *S* of an elementary type *T*, the following representation attribute is defined:

1.2/3 S'Stream_Size

{AI95-00270-01} {AI05-0194-1} Denotes the number of bits read from or written to a stream by the default implementations of S'Read and S'Write. Hence, the number of stream elements required per item of elementary type *T* is:

1.3/2 $T'Stream_Size / Ada.Streams.Stream_Element'Size$

1.4/2 The value of this attribute is of type *universal_integer* and is a multiple of Stream_Element'Size.

1.5/2 Stream_Size may be specified for first subtypes via an *attribute_definition_clause*; the expression of such a clause shall be static, nonnegative, and a multiple of Stream_Element'Size.

1.a/3 **Aspect Description for Stream_Size:** Size in bits used to represent elementary objects in a stream.

1.b/2 **Discussion:** Stream_Size is a type-related attribute (see 13.1).

1.c/3 **Ramification:** {AI05-0194-1} The value of S'Stream_Size is unaffected by the presence or absence of any *attribute_definition_clause* or *aspect_specifications* specifying the Read or Write attributes of any ancestor of S. S'Stream_Size is defined in terms of the behavior of the default implementations of S'Read and S'Write even if those default implementations are overridden.

Implementation Advice

1.6/2 {AI95-00270-01} If not specified, the value of Stream_Size for an elementary type should be the number of bits that corresponds to the minimum number of stream elements required by the first subtype of the type, rounded up to the nearest factor or multiple of the word size that is also a multiple of the stream element size.

1.d/2 **Implementation Advice:** If not specified, the value of Stream_Size for an elementary type should be the number of bits that corresponds to the minimum number of stream elements required by the first subtype of the type, rounded up to the nearest factor or multiple of the word size that is also a multiple of the stream element size.

1.e/2 **Reason:** {AI95-00270-01} This is Implementation Advice because we want to allow implementations to remain compatible with their Ada 95 implementations, which may have a different handling of the number of stream elements. Users can always specify Stream_Size if they need a specific number of stream elements.

1.7/2 {AI95-00270-01} The recommended level of support for the Stream_Size attribute is:

- 1.8/2 • {AI95-00270-01} A Stream_Size clause should be supported for a discrete or fixed point type *T* if the specified Stream_Size is a multiple of Stream_Element'Size and is no less than the size of the first subtype of *T*, and no greater than the size of the largest type of the same elementary class (signed integer, modular integer, enumeration, ordinary fixed point, or decimal fixed point).

1.f/2 **Implementation Advice:** The recommended level of support for the Stream_Size attribute should be followed.

1.g/2 **Ramification:** There are no requirements beyond supporting confirming Stream_Size clauses for floating point and access types. Floating point and access types usually only have a handful of defined formats, streaming anything else makes no sense for them.

1.h/2 For discrete and fixed point types, this may require support for sizes other than the “natural” ones. For instance, on a typical machine with 32-bit integers and a Stream_Element'Size of 8, setting Stream_Size to 24 must be supported. This is required as such formats can be useful for interoperability with unusual machines, and there is no difficulty with the implementation (drop extra bits on output, sign extend on input).

Static Semantics

- For every subtype S of a specific type T , the following attributes are defined. 2
- S'Write** S'Write denotes a procedure with the following specification: 3
- ```
{AI95-00441-01} procedure S'Write(
 Stream : not null access Ada.Streams.Root_Stream_Type'Class;
 Item : in T)
```
- 4/2
- S'Write writes the value of *Item* to *Stream*. 5
- S'Read** S'Read denotes a procedure with the following specification: 6
- ```
{AI95-00441-01} procedure S'Read(  
    Stream : not null access Ada.Streams.Root_Stream_Type'Class;  
    Item : out T)
```
- 7/2
- S'Read reads the value of *Item* from *Stream*. 8
- {8652/0040} {AI95-00108-01} {AI95-00444-01} {AI05-0192-1} For an untagged derived type, the Write (resp. Read) attribute is inherited according to the rules given in 13.1 if the attribute is [specified and] available for the parent type at the point where T is declared. For a tagged derived type, these attributes are not inherited, but rather the default implementations are used. 8.1/3
- Proof:** {AI05-0192-1} The inheritance rules of 13.1 say that only specified or inherited aspects are inherited; we mention it again here as a clarification. 8.a.1/3
- {AI95-00444-01} The default implementations of the Write and Read attributes, where available, execute as follows: 8.2/2
- {8652/0040} {AI95-00108-01} {AI95-00195-01} {AI95-00251-01} {AI95-00270-01} {AI05-0139-2} 9/3
- For elementary types, Read reads (and Write writes) the number of stream elements implied by the *Stream_Size* for the type T ; the representation of those stream elements is implementation defined. For composite types, the Write or Read attribute for each component is called in canonical order, which is last dimension varying fastest for an array (unless the convention of the array is Fortran, in which case it is first dimension varying fastest), and positional aggregate order for a record. Bounds are not included in the stream if T is an array type. If T is a discriminated type, discriminants are included only if they have defaults. If T is a tagged type, the tag is not included. For type extensions, the Write or Read attribute for the parent type is called, followed by the Write or Read attribute of each component of the extension part, in canonical order. For a limited type extension, if the attribute of the parent type or any progenitor type of T is available anywhere within the immediate scope of T , and the attribute of the parent type or the type of any of the extension components is not available at the freezing point of T , then the attribute of T shall be directly specified.
- Implementation defined:** The contents of the stream elements read and written by the Read and Write attributes of elementary types. 9.a/2
- {AI05-0023-1} {AI05-0264-1} If T is a discriminated type and its discriminants have defaults, then S'Read first reads the discriminants from the stream without modifying *Item*. S'Read then creates an object of type T constrained by these discriminants. The value of this object is then converted to the subtype of *Item* and is assigned to *Item*. Finally, the Read attribute for each nondiscriminant component of *Item* is called in canonical order as described above. Normal default initialization and finalization take place for the created object. 9.1/3
- Reason:** A discriminant with a default value is treated simply as a component of the object. On the other hand, an array bound or a discriminant without a default value, is treated as “descriptor” or “dope” that must be provided in order to create the object and thus is logically separate from the regular components. Such “descriptor” data are written by 'Output and produced as part of the delivered result by the 'Input function, but they are not written by 'Write nor read by 'Read. A tag is like a discriminant without a default. 9.b

- 9.b.1/1 {8652/0040} {AI95-00108-01} For limited type extensions, we must have a definition of 'Read and 'Write if the parent type has one, as it is possible to make a dispatching call through the attributes. The rule is designed to automatically do the right thing in as many cases as possible.
- 9.b.2/1 {AI95-00251-01} Similarly, a type that has a progenitor with an available attribute must also have that attribute, for the same reason.
- 9.b.3/3 {AI05-0023-1} The semantics of S'Read for a discriminated type with defaults involves an anonymous object so that the point of required initialization and finalization is well-defined, especially for objects that change shape and have controlled components. The creation of this anonymous object often can be omitted (see the Implementation Permissions below).
- 9.c/2 **Ramification:** {AI95-00195-01} For a composite object, the subprogram denoted by the Write or Read attribute of each component is called, whether it is the default or is user-specified. Implementations are allowed to optimize these calls (see below), presuming the properties of the attributes are preserved.
- 9.2/3 {AI95-00270-01} {AI05-0264-1} Constraint_Error is raised by the predefined Write attribute if the value of the elementary item is outside the range of values representable using Stream_Size bits. For a signed integer type, an enumeration type, or a fixed point type, the range is unsigned only if the integer code for the lower bound of the first subtype is nonnegative, and a (symmetric) signed range that covers all values of the first subtype would require more than Stream_Size bits; otherwise, the range is signed.
- 10 For every subtype S'Class of a class-wide type T'Class:
- 11 S'Class'Write
- S'Class'Write denotes a procedure with the following specification:
- 12/2 {AI95-00441-01} **procedure** S'Class'Write(
 Stream : **not null access** Ada.Streams.Root_Stream_Type'Class;
 Item : **in** T'Class)
- 13 Dispatches to the subprogram denoted by the Write attribute of the specific type identified by the tag of Item.
- 14 S'Class'Read
- S'Class'Read denotes a procedure with the following specification:
- 15/2 {AI95-00441-01} **procedure** S'Class'Read(
 Stream : **not null access** Ada.Streams.Root_Stream_Type'Class;
 Item : **out** T'Class)
- 16 Dispatches to the subprogram denoted by the Read attribute of the specific type identified by the tag of Item.
- 16.a **Reason:** It is necessary to have class-wide versions of Read and Write in order to avoid generic contract model violations; in a generic, we don't necessarily know at compile time whether a given type is specific or class-wide.

Paragraph 17 was deleted.

Static Semantics

- 18 For every subtype S of a specific type T, the following attributes are defined.
- 19 S'Output S'Output denotes a procedure with the following specification:
- 20/2 {AI95-00441-01} **procedure** S'Output(
 Stream : **not null access** Ada.Streams.Root_Stream_Type'Class;
 Item : **in** T)
- 21 S'Output writes the value of Item to Stream, including any bounds or discriminants.
- 21.a **Ramification:** Note that the bounds are included even for an array type whose first subtype is constrained.
- 22 S'Input S'Input denotes a function with the following specification:
- 23/2 {AI95-00441-01} **function** S'Input(
 Stream : **not null access** Ada.Streams.Root_Stream_Type'Class)
 return T
- 24 S'Input reads and returns one value from Stream, using any bounds or discriminants written by a corresponding S'Output to determine how much to read.

{8652/0040} {AI95-00108-01} {AI95-00444-01} {AI05-0192-1} For an untagged derived type, the Output (resp. Input) attribute is inherited according to the rules given in 13.1 if the attribute is [specified and] available for the parent type at the point where *T* is declared. For a tagged derived type, these attributes are not inherited, but rather the default implementations are used. 25/3

Proof: {AI05-0192-1} See the note following the inheritance rules for the Write attribute, above. 25.a/3

{AI95-00444-01} The default implementations of the Output and Input attributes, where available, execute as follows: 25.1/2

- {AI05-0269-1} If *T* is an array type, S'Output first writes the bounds, and S'Input first reads the bounds. If *T* has discriminants without defaults, S'Output first writes the discriminants (using the Write attribute of the discriminant type for each), and S'Input first reads the discriminants (using the Read attribute of the discriminant type for each). 26/3
- {AI95-00195-01} {AI05-0023-1} S'Output then calls S'Write to write the value of *Item* to the stream. S'Input then creates an object of type *T*, with the bounds or (when without defaults) the discriminants, if any, taken from the stream, passes it to S'Read, and returns the value of the object. If *T* has discriminants, then this object is unconstrained if and only the discriminants have defaults. Normal default initialization and finalization take place for this object (see 3.3.1, 7.6, and 7.6.1). 27/3

{AI95-00251-01} If *T* is an abstract type, then S'Input is an abstract function. 27.1/2

Ramification: For an abstract type *T*, S'Input can be called in a dispatching call, or passed to an abstract formal subprogram. But it cannot be used in nondispatching contexts, because we don't allow objects of abstract types to exist. The designation of this function as abstract has no impact on descendants of *T*, as *T*Input is not inherited for tagged types, but rather recreated (and the default implementation of *T*Input calls *T*Read, not the parent type's *T*Input). Note that *T*Input cannot be specified in this case, as any function with the proper profile is necessarily abstract, and specifying abstract subprograms in an `attribute_definition_clause` is illegal. 27.a/2

For every subtype S'Class of a class-wide type *T*Class: 28

S'Class'Output 29

S'Class'Output denotes a procedure with the following specification:

```
{AI95-00441-01} procedure S'Class'Output (
    Stream : not null access Ada.Streams.Root_Stream_Type'Class;
    Item   : in T'Class)
```

 30/2

{AI95-00344-01} First writes the external tag of *Item* to *Stream* (by calling String'Output(*Stream*, Tags.External_Tag(*Item*'Tag)) — see 3.9) and then dispatches to the subprogram denoted by the Output attribute of the specific type identified by the tag. Tag_Error is raised if the tag of *Item* identifies a type declared at an accessibility level deeper than that of S. 31/2

Reason: {AI95-00344-01} We raise Tag_Error here for nested types as such a type cannot be successfully read with S'Class'Input, and it doesn't make sense to allow writing a value that cannot be read. 31.a/2

S'Class'Input 32

S'Class'Input denotes a function with the following specification:

```
{AI95-00441-01} function S'Class'Input (
    Stream : not null access Ada.Streams.Root_Stream_Type'Class)
return T'Class
```

 33/2

{AI95-00279-01} {AI95-00344-01} {AI05-0109-1} First reads the external tag from *Stream* and determines the corresponding internal tag (by calling Tags.Descendant_Tag(String'Input(*Stream*), S'Tag) which might raise Tag_Error — see 3.9) and then dispatches to the subprogram denoted by the Input attribute of the specific type identified by the internal tag; returns that result. If the specific type identified by the internal tag is abstract, Constraint_Error is raised. 34/3

Ramification: {AI05-0109-1} Descendant_Tag will ensure that the tag it returns is covered by T'Class; Tag_Error will be raised if it would not cover T'Class. 34.a/3

- 35/3 {AI95-00195-01} {AI05-0228-1} In the default implementation of Read and Input for a composite type, for each scalar component that is a discriminant or that has an implicit initial value, a check is made that the value returned by Read for the component belongs to its subtype. Constraint_Error is raised if this check fails. For other scalar components, no check is made. For each component that is of an access type, if the implementation can detect that the value returned by Read for the component is not a value of its subtype, Constraint_Error is raised. If the value is not a value of its subtype and this error is not detected, the component has an abnormal value, and erroneous execution can result (see 13.9.1). In the default implementation of Read for a composite type with defaulted discriminants, if the actual parameter of Read is constrained, a check is made that the discriminants read from the stream are equal to those of the actual parameter. Constraint_Error is raised if this check fails.
- 35.a/3 **Reason:** {AI05-0228-1} The check for scalar components that have an implicit initial value is to preserve our Language Design Principle that all objects that have an implicit initial value do not become "deinitialized".
- 35.b/3 **Ramification:** {AI05-0228-1} A scalar component can have an implicit initial value if it has a default_expression, if the component's type has the Default_Value aspect specified, or if the component is that of an array type that has the Default_Component_Value aspect specified.
- 35.c/3 **To be honest:** {AI05-0228-1} An implementation should always be able to detect the error for a null value read into a component of an access subtype with a null exclusion; the "if the implementation can detect" is intended to cover nonnull access values.
- 36/2 {AI95-00195-01} It is unspecified at which point and in which order these checks are performed. In particular, if Constraint_Error is raised due to the failure of one of these checks, it is unspecified how many stream elements have been read from the stream.
- 37/1 {8652/0045} {AI95-00132-01} In the default implementation of Read and Input for a type, End_Error is raised if the end of the stream is reached before the reading of a value of the type is completed.
- 38/3 {8652/0040} {AI95-00108-01} {AI95-00195-01} {AI95-00251-01} {AI05-0039-1} The stream-oriented attributes may be specified for any type via an attribute_definition_clause. The subprogram name given in such a clause shall statically denote a subprogram that is not an abstract subprogram. Furthermore, if a stream-oriented attribute is specified for an interface type by an attribute_definition_clause, the subprogram name given in the clause shall statically denote a null procedure.
- 38.a/2 *This paragraph was deleted.* {AI95-00195-01}
- 38.a.1/2 *This paragraph was deleted.* {8652/0040} {AI95-00108-01} {AI95-00195-01}
- 38.b/2 **Discussion:** {AI95-00251-01} Stream attributes (other than Input) are always null procedures for interface types (they have no components). We need to allow explicit setting of the Read and Write attributes in order that the class-wide attributes like L'Class'Input can be made available. (In that case, any descendant of the interface type would require available attributes.) But we don't allow any concrete implementation because these don't participate in extensions (unless the interface is the parent type). If we didn't ban concrete implementations, the order of declaration of a pair of interfaces would become significant. For example, if Int1 and Int2 are interfaces with concrete implementations of 'Read, then the following declarations would have different implementations for 'Read:
- 38.c/2

```
type Con1 is new Int1 and Int2 with null record;
type Con2 is new Int2 and Int1 with null record;
```
- 38.d/2 This would violate our design principle that the order of the specification of the interfaces in a derived_type_definition doesn't matter.
- 38.e/2 **Ramification:** The Input attribute cannot be specified for an interface. As it is a function, a null procedure is impossible; a concrete function is not possible anyway as any function returning an abstract type must be abstract. And we don't allow specifying stream attributes to be abstract subprograms. This has no impact, as the availability of Int'Class'Input (where Int is a limited interface) depends on whether Int'Read (not Int'Input) is specified. There is no reason to allow Int'Output to be specified, either, but there is equally no reason to disallow it, so we don't have a special rule for that.
- 38.f/2 **Discussion:** {AI95-00195-01} Limited types generally do not have default implementations of the stream-oriented attributes. The rules defining when a stream-oriented attribute is available (see below) determine when an attribute of a limited type is in fact well defined and usable. The rules are designed to maximize the number of cases in which the attributes are usable. For instance, when the language provides a default implementation of an attribute for a limited type based on a specified attribute for the parent type, we want to be able to call that attribute.

Aspect Description for Read: Procedure to read a value from a stream for a given type.	38.g/3
Aspect Description for Write: Procedure to write a value to a stream for a given type.	38.h/3
Aspect Description for Input: Function to read a value from a stream for a given type, including any bounds and discriminants.	38.i/3
Aspect Description for Output: Procedure to write a value to a stream for a given type, including any bounds and discriminants.	38.j/3
<i>{AI95-00195-01}</i> A stream-oriented attribute for a subtype of a specific type <i>T</i> is <i>available</i> at places where one of the following conditions is true:	39/2
<ul style="list-style-type: none"> • <i>T</i> is nonlimited. 	40/2
<ul style="list-style-type: none"> • The <code>attribute_designator</code> is Read (resp. Write) and <i>T</i> is a limited record extension, and the attribute Read (resp. Write) is available for the parent type of <i>T</i> and for the types of all of the extension components. 	41/2
Reason: In this case, the language provides a well-defined default implementation, which we want to be able to call.	41.a/2
<ul style="list-style-type: none"> • <i>T</i> is a limited untagged derived type, and the attribute was inherited for the type. 	42/2
Reason: Attributes are only inherited for untagged derived types, and surely we want to be able to call inherited attributes.	42.a/2
<ul style="list-style-type: none"> • The <code>attribute_designator</code> is Input (resp. Output), and <i>T</i> is a limited type, and the attribute Read (resp. Write) is available for <i>T</i>. 	43/2
Reason: The default implementation of Input and Output are based on Read and Write; so if the implementation of Read or Write is good, so is the matching implementation of Input or Output.	43.a/2
<ul style="list-style-type: none"> • The attribute has been specified via an <code>attribute_definition_clause</code>, and the <code>attribute_definition_clause</code> is visible. 	44/2
Reason: We always want to allow calling a specified attribute. But we don't want availability to break privacy. Therefore, only attributes whose specification can be seen count. Yes, we defined the visibility of an <code>attribute_definition_clause</code> (see 8.3).	44.a/2
<i>{AI95-00195-01}</i> A stream-oriented attribute for a subtype of a class-wide type <i>TClass</i> is available at places where one of the following conditions is true:	45/2
<ul style="list-style-type: none"> • <i>T</i> is nonlimited; 	46/2
<ul style="list-style-type: none"> • the attribute has been specified via an <code>attribute_definition_clause</code>, and the <code>attribute_definition_clause</code> is visible; or 	47/2
<ul style="list-style-type: none"> • the corresponding attribute of <i>T</i> is available, provided that if <i>T</i> has a partial view, the corresponding attribute is available at the end of the visible part where <i>T</i> is declared. 	48/2
Reason: The rules are stricter for class-wide attributes because (for the default implementation) we must ensure that any specific attribute that might ever be dispatched to is available. Because we require specification of attributes for extensions of limited parent types with available attributes, we can in fact know this. Otherwise, we would not be able to use default class-wide attributes with limited types, a significant limitation.	48.a/2
<i>{AI95-00195-01}</i> An <code>attribute_reference</code> for one of the stream-oriented attributes is illegal unless the attribute is available at the place of the <code>attribute_reference</code> . Furthermore, an <code>attribute_reference</code> for <i>T</i> Input is illegal if <i>T</i> is an abstract type.	49/2
Discussion: Stream attributes always exist. It is illegal to call them in some cases. Having the attributes not be defined for some limited types would seem to be a cleaner solution, but it would lead to contract model problems for limited private types.	49.a/2
<i>T</i> Input is available for abstract types so that <i>TClass</i> 'Input is available. But we certainly don't want to allow calls that could create an object of an abstract type. Remember that <i>TClass</i> is never abstract, so the above legality rule doesn't apply to it. We don't have to discuss whether the attribute is specified, as it cannot be: any function returning the type would have to be abstract, and we do not allow specifying an attribute with an abstract subprogram.	49.b/2

- 50/3 {AI95-00195-01} {AI05-0192-1} In the `parameter_and_result_profiles` for the default implementations of the stream-oriented attributes, the subtype of the `Item` parameter is the base subtype of T if T is a scalar type, and the first subtype otherwise. The same rule applies to the result of the `Input` attribute.
- 50.a/3 **Discussion:** {AI05-0192-1} An inherited stream attribute has a profile as determined by the rules for inheriting primitive subprograms (see 13.1 and 3.4).
- 51/3 {AI95-00195-01} {AI05-0007-1} For an `attribute_definition_clause` specifying one of these attributes, the subtype of the `Item` parameter shall be the first subtype or the base subtype if scalar, and the first subtype if not scalar. The same rule applies to the result of the `Input` function.
- 51.a/2 **Reason:** This is to simplify implementation.
- 51.b/3 **Ramification:** The view of the type at the point of the `attribute_definition_clause` determines whether the base subtype is allowed. Thus, for a scalar type with a partial view (which is never scalar), whether the base subtype is allowed is determined by whether the `attribute_definition_clause` occurs before or after the full definition of the scalar type.
- 52/3 {AI95-00366-01} {AI05-0065-1} [A type is said to *support external streaming* if `Read` and `Write` attributes are provided for sending values of such a type between active partitions, with `Write` marshalling the representation, and `Read` unmarshalling the representation.] A limited type supports external streaming only if it has available `Read` and `Write` attributes. A type with a part that is of a nonremote access type supports external streaming only if that access type or the type of some part that includes the access type component, has `Read` and `Write` attributes that have been specified via an `attribute_definition_clause`, and that `attribute_definition_clause` is visible. [An anonymous access type does not support external streaming.]All other types (including remote access types, see E.2.2) support external streaming.
- 52.a/3 **Ramification:** A limited type with a part that is of a nonremote access type needs to satisfy both rules.

Erroneous Execution

- 53/2 {AI95-00279-01} {AI95-00344-01} If the internal tag returned by `Descendant_Tag` to `T'Class'Input` identifies a type that is not library-level and whose tag has not been created, or does not exist in the partition at the time of the call, execution is erroneous.
- 53.a/2 **Ramification:** The definition of `Descendant_Tag` prevents such a tag from being provided to `T'Class'Input` if T is a library-level type. However, this rule is needed for nested tagged types.

Implementation Requirements

- 54/1 {8652/0040} {AI95-00108-01} For every subtype S of a language-defined nonlimited specific type T , the output generated by `S'Output` or `S'Write` shall be readable by `S'Input` or `S'Read`, respectively. This rule applies across partitions if the implementation conforms to the Distributed Systems Annex.
- 55/3 {AI95-00195-01} {AI05-0092-1} If `Constraint_Error` is raised during a call to `Read` because of failure of one the above checks, the implementation shall ensure that the discriminants of the actual parameter of `Read` are not modified.

Implementation Permissions

- 56/3 {AI95-00195-01} {AI05-0092-1} The number of calls performed by the predefined implementation of the stream-oriented attributes on the `Read` and `Write` operations of the stream type is unspecified. An implementation may take advantage of this permission to perform internal buffering. However, all the calls on the `Read` and `Write` operations of the stream type needed to implement an explicit invocation of a stream-oriented attribute shall take place before this invocation returns. An explicit invocation is one appearing explicitly in the program text, possibly through a generic instantiation (see 12.3).
- 56.1/3 {AI05-0023-1} {AI05-0264-1} If T is a discriminated type and its discriminants have defaults, then in two cases an execution of the default implementation of `S'Read` is not required to create an anonymous object

of type *T*: If the discriminant values that are read in are equal to the corresponding discriminant values of *Item*, then no object of type *T* need be created and *Item* may be used instead. If they are not equal and *Item* is a constrained variable, then `Constraint_Error` may be raised at that point, before any further values are read from the stream and before the object of type *T* is created.

{AI05-0023-1} A default implementation of `S'Input` that calls the default implementation of `S'Read` may create a constrained anonymous object with discriminants that match those in the stream. 56.2/3

Implementation Note: This allows the combined executions of `S'Input` and `S'Read` to create one object of type *T* instead of two. If this option is exercised, then: 56.a/3

- The discriminants are read from the stream by `S'Input`, not `S'Read`. 56.b/3
- `S'Input` declares an object of type *T* constrained by the discriminants read from the stream, not an unconstrained object. 56.c/3
- The discriminant values that `S'Read` would normally have read from the stream are read from *Item* instead. 56.d/3
- The permissions of the preceding paragraph then apply and no object of type *T* need be created by the execution of `S'Read`. 56.e/3

NOTES

40 For a definite subtype *S* of a type *T*, only *T'Write* and *T'Read* are needed to pass an arbitrary value of the subtype through a stream. For an indefinite subtype *S* of a type *T*, *T'Output* and *T'Input* will normally be needed, since *T'Write* and *T'Read* do not pass bounds, discriminants, or tags. 57

41 User-specified attributes of `S'Class` are not inherited by other class-wide types descended from *S*. 58

Examples

Example of user-defined Write attribute: 59

```
{AI95-00441-01} procedure My_Write(
  Stream : not null access Ada.Streams.Root_Stream_Type'Class;
  Item   : My_Integer'Base);
for My_Integer'Write use My_Write; 60/2
```

Discussion: *Example of network input/output using input output attributes:* 60.a

```
with Ada.Streams; use Ada.Streams; 60.b
```

```
generic
  type Msg_Type(<>) is private;
package Network_IO is
  -- Connect/Disconnect are used to establish the stream
  procedure Connect(...);
  procedure Disconnect(...);
  -- Send/Receive transfer messages across the network
  procedure Send(X : in Msg_Type); 60.c
  function Receive return Msg_Type;
```

```
private
  type Network_Stream is new Root_Stream_Type with ...
  procedure Read(...); -- define Read/Write for Network_Stream
  procedure Write(...);
end Network_IO;
```

```
with Ada.Streams; use Ada.Streams; 60.d
```

```
package body Network_IO is
  Current_Stream : aliased Network_Stream;
  . . .
  procedure Connect(...) is ...;
  procedure Disconnect(...) is ...;
```

```
  procedure Send(X : in Msg_Type) is 60.e
  begin
    Msg_Type'Output(Current_Stream'Access, X);
  end Send;
```

```
  function Receive return Msg_Type is 60.f
  begin
```

```
    return Msg_Type'Input(Current_Stream'Access);
  end Receive;
end Network_IO;
```

Inconsistencies With Ada 95

- 60.g/2 {8652/0040} {AI95-00108-01} **Corrigendum:** Clarified how the default implementation for stream attributes is determined (eliminating conflicting language). The new wording provides that attributes for type extensions are created by composing the parent's attribute with those for the extension components if any. If a program was written assuming that the extension components were not included in the stream (as in original Ada 95), it would fail to work in the language as corrected by the Corrigendum.
- 60.h/2 {AI95-00195-01} **Amendment Correction:** Explicitly provided a permission that the number of calls to the underlying stream Read and Write operations may differ from the number determined by the canonical operations. If Ada 95 code somehow depended on the number of calls to Read or Write, it could fail with an Ada 2005 implementation. Such code is likely to be very rare; moreover, such code is really wrong, as the permission applies to Ada 95 as well.

Extensions to Ada 95

- 60.i/2 {AI95-00270-01} The Stream_Size attribute is new. It allows specifying the number of bits that will be streamed for a type. The Implementation Advice involving this also was changed; this is not incompatible because Implementation Advice does not have to be followed.
- 60.j/2 {8652/0040} {AI95-00108-01} {AI95-00195-01} {AI95-00444-01} **Corrigendum:** Limited types may have default constructed attributes if all of the parent and (for extensions) extension components have available attributes. Ada 2005 adds the notion of availability to patch up some holes in the Corrigendum model.

Wording Changes from Ada 95

- 60.k/2 {8652/0009} {AI95-00137-01} **Corrigendum:** Added wording to specify that these are operational attributes.
- 60.l/2 {8652/0045} {AI95-00132-01} **Corrigendum:** Clarified that End_Error is raised by the default implementation of Read and Input if the end of the stream is reached. (The result could have been abnormal without this clarification, thus this is not an inconsistency, as the programmer could not have depended on the previous behavior.)
- 60.m/2 {AI95-00195-01} Clarified that the default implementation of S'Input does normal initialization on the object that it passes to S'Read.
- 60.n/2 {AI95-00195-01} Explicitly stated that what is read from a stream when a required check fails is unspecified.
- 60.o/2 {AI95-00251-01} Defined availability and default implementations for types with progenitors.
- 60.p/2 {AI95-00279-01} Specified that Constraint_Error is raised if the internal tag retrieved for S'Class'Input is for some type not covered by S'Class or is abstract. We also explicitly state that the program is erroneous if the tag has not been created or does not currently exist in the partition. (Ada 95 did not specify what happened in these cases; it's very unlikely to have provided some useful result, so this is not considered an inconsistency.)
- 60.q/2 {AI95-00344-01} Added wording to support nested type extensions. S'Input and S'Output always raise Tag_Error for such extensions, and such extensions were not permitted in Ada 95, so this is neither an extension nor an incompatibility.
- 60.r/2 {AI95-00366-01} Defined *supports external streaming* to put all of the rules about “good” stream attributes in one place. This is used for distribution and for defining pragma Pure.
- 60.s/2 {AI95-00441-01} Added the **not null** qualifier to the first parameter of all of the stream attributes, so that the semantics doesn't change between Ada 95 and Ada 2005. This change is compatible, because mode conformance is required for subprograms specified as stream attributes, and null_exclusions are not considered for mode conformance.
- 60.t/2 {AI95-00444-01} Improved the wording to make it clear that we don't define the default implementations of attributes that cannot be called (that is, aren't “available”). Also clarified when inheritance takes place.

Incompatibilities With Ada 2005

- 60.u/3 {AI05-0039-1} **Correction:** Added a requirement that stream attributes be specified by a static subprogram name rather than a dynamic expression. Expressions cannot provide any useful functionality because of the freezing rules, and the possibility of them complicates implementations. Only pathological programs should be affected.

Extensions to Ada 2005

- 60.v/3 {AI05-0007-1} **Correction:** Stream attributes for scalar types can be specified with subprograms that take the first subtype as well as the base type. This eliminates confusion about which subtype is appropriate for attributes specified for partial views whose full type is a scalar type. It also eliminates a common user error (forgetting 'Base).

Wording Changes from Ada 2005

{AI05-0023-1}	Correction: Corrected the definition of the default version S'Read and S'Input to be well-defined if S is a discriminated type with defaulted discriminants and some components require initialization and/or finalizations.	60.w/3
{AI05-0065-1}	Correction: Defined remote access types to support external streaming, since that is their purpose.	60.x/3
{AI05-0109-1}	Correction: Removed a misleading phrase which implies that Constraint_Error is raised for internal tags of the wrong type, when Tag_Error should be raised for such tags.	60.y/3
{AI05-0139-2}	Clarified that arrays with convention Fortran are written in column-major order, rather than row-major order. This is necessary in order that streaming of Fortran arrays is efficient.	60.z/3
{AI05-0192-1}	Correction: Clarified that the profile of an inherited stream attribute is as defined for an inherited primitive subprogram, while the default implementation of the same attribute might have a different profile.	60.aa/3
{AI05-0194-1}	Correction: Clarified that Stream_Size has no effect on and is not effected by user-defined stream attributes.	60.bb/3

13.14 Freezing Rules

{AI05-0299-1} [This subclause defines a place in the program text where each declared entity becomes “frozen.” A use of an entity, such as a reference to it by name, or (for a type) an expression of the type, causes freezing of the entity in some contexts, as described below. The Legality Rules forbid certain kinds of uses of an entity in the region of text where it is frozen.] 1/3

Reason: This concept has two purposes: a compile-time one and a run-time one. 1.a

The compile-time purpose of the freezing rules comes from the fact that the evaluation of static expressions depends on overload resolution, and overload resolution sometimes depends on the value of a static expression. (The dependence of static evaluation upon overload resolution is obvious. The dependence in the other direction is more subtle. There are three rules that require static expressions in contexts that can appear in declarative places: The expression in an `attribute_designator` shall be static. In a record aggregate, variant-controlling discriminants shall be static. In an array aggregate with more than one named association, the choices shall be static. The compiler needs to know the value of these expressions in order to perform overload resolution and legality checking.) We wish to allow a compiler to evaluate static expressions when it sees them in a single pass over the `compilation_unit`. The freezing rules ensure that. 1.b

The run-time purpose of the freezing rules is called the “linear elaboration model.” This means that declarations are elaborated in the order in which they appear in the program text, and later elaborations can depend on the results of earlier ones. The elaboration of the declarations of certain entities requires run-time information about the implementation details of other entities. The freezing rules ensure that this information has been calculated by the time it is used. For example, suppose the initial value of a constant is the result of a function call that takes a parameter of type *T*. In order to pass that parameter, the size of type *T* has to be known. If *T* is composite, that size might be known only at run time. 1.c

(Note that in these discussions, words like “before” and “after” generally refer to places in the program text, as opposed to times at run time.) 1.d

Discussion: The “implementation details” we’re talking about above are: 1.e

- For a tagged type, the implementations of all the primitive subprograms of the type — that is (in the canonical implementation model), the contents of the type descriptor, which contains pointers to the code for each primitive subprogram. 1.f
- For a type, the full type declaration of any parts (including the type itself) that are private. 1.g
- For a deferred constant, the full constant declaration, which gives the constant’s value. (Since this information necessarily comes after the constant’s type and subtype are fully known, there’s no need to worry about its type or subtype.) 1.h
- For any entity, representation information specified by the user via representation items. Most representation items are for types or subtypes; however, various other kinds of entities, such as objects and subprograms, are possible. 1.i

{AI05-0005-1} Similar issues arise for incomplete types. However, we do not use freezing to prevent premature access; incomplete types have different, more severe, restrictions. Similar issues also arise for subprograms, protected operations, tasks and generic units. However, we do not use freezing to prevent premature access for those, either; 3.11 prevents problems with run-time `Elaboration_Checks`. Even so, freezing is used for these entities to prevent giving representation items too late (that is, after uses that require representation information, such as calls). 1.j/3

- 1.k An evaluable construct should freeze anything that's needed to evaluate it.
- 1.l However, if the construct is not evaluated where it appears, let it cause freezing later, when it is evaluated. This is the case for `default_expressions` and `default_names`. (Formal parameters, generic formal parameters, and components can have `default_expressions` or `default_names`.)
- 1.m The compiler should be allowed to evaluate static expressions without knowledge of their context. (I.e. there should not be any special rules for static expressions that happen to occur in a context that requires a static expression.)
- 1.n Compilers should be allowed to evaluate static expressions (and record the results) using the run-time representation of the type. For example, suppose `Color'Pos(Red) = 1`, but the internal code for `Red` is 37. If the value of a static expression is `Red`, some compilers might store 1 in their symbol table, and other compilers might store 37. Either compiler design should be feasible.
- 1.o Compilers should never be required to detect erroneous-ness or exceptions at compile time (although it's very nice if they do). This implies that we should not require code-generation for a nonstatic expression of type *T* too early, even if we can prove that that expression will be erroneous, or will raise an exception.
- 1.p Here's an example (modified from AI83-00039, Example 3):
- 1.q
- ```

type T is
 record
 ...
 end record;
function F return T;
function G(X : T) return Boolean;
Y : Boolean := G(F); -- doesn't force T in Ada 83
for T use
 record
 ...
 end record;

```
- 1.r AI83-00039 says this is legal. Of course, it raises `Program_Error` because the function bodies aren't elaborated yet. A one-pass compiler has to generate code for an expression of type *T* before it knows the representation of *T*. Here's a similar example, which AI83-00039 also says is legal:
- 1.s
- ```

package P is
  type T is private;
  function F return T;
  function G(X : T) return Boolean;
  Y : Boolean := G(F); -- doesn't force T in Ada 83
private
  type T is
    record
      ...
    end record;
end P;

```
- 1.t If *T*'s size were dynamic, that size would be stored in some compiler-generated dope; this dope would be initialized at the place of the full type declaration. However, the generated code for the function calls would most likely allocate a temp of the size specified by the dope *before* checking for `Program_Error`. That dope would contain uninitialized junk, resulting in disaster. To avoid doing that, the compiler would have to determine, at compile time, that the expression will raise `Program_Error`.
- 1.u This is silly. If we're going to require compilers to detect the exception at compile time, we might as well formulate the rule as a legality rule.
- 1.v Compilers should not be required to generate code to load the value of a variable before the address of the variable has been determined.
- 1.w After an entity has been frozen, no further requirements may be placed on its representation (such as by a representation item or a `full_type_declaration`).
- 2 The *freezing* of an entity occurs at one or more places (*freezing points*) in the program text where the representation for the entity has to be fully determined. Each entity is frozen from its first freezing point to the end of the program text (given the ordering of compilation units defined in 10.1.4).
- 2.a **Ramification:** The “representation” for a subprogram includes its calling convention and means for referencing the subprogram body, either a “link-name” or specified address. It does not include the code for the subprogram body itself, nor its address if a link-name is used to reference the body.
- 2.1/3 *{AI05-0019-1}* *{AI05-0299-1}* This subclause also defines a place in the program text where the profile of each declared callable entity becomes *frozen*. A use of a callable entity causes freezing of its profile in

some contexts, as described below. At the place where the profile of a callable entity becomes frozen, the entity itself becomes frozen.

{8652/0014} {AI05-0017-1} {AI05-0019-1} The end of a `declarative_part`, `protected_body`, or a declaration of a library package or generic library package, causes *freezing* of each entity and profile declared within it, except for incomplete types. A noninstance body other than a `renames-as-body` causes freezing of each entity and profile declared before it within the same `declarative_part` that is not an incomplete type; it only causes freezing of an incomplete type if the body is within the immediate scope of the incomplete type. 3/3

Discussion: This is worded carefully to handle nested packages and private types. Entities declared in a nested `package_specification` will be frozen by some containing construct. 3.a

{AI05-0017-1} An incomplete type declared in the private part of a library `package_specification` can be completed in the body. For other incomplete types (and in the bodies of library packages), the completion of the type will be frozen at the end of the package or `declarative_part`, and that will freeze the incomplete view as well. 3.b/3

{AI05-0017-1} The reason we have to worry about freezing of incomplete types is to prevent premature uses of the types in dispatching calls. Such uses may need access to the tag of the type, and the type has to be frozen to know where the tag is stored. 3.b.1/3

Ramification: {AI05-0229-1} The part about bodies does not say *immediately* within. A renaming-as-body does not have this property. Nor does an imported body 3.c/3

Reason: The reason bodies cause freezing is because we want `proper_bodies` and `body_stubs` to be interchangeable — one should be able to move a `proper_body` to a subunit, and vice-versa, without changing the semantics. Clearly, anything that should cause freezing should do so even if it's inside a `proper_body`. However, if we make it a `body_stub`, then the compiler can't see that thing that should cause freezing. So we make `body_stubs` cause freezing, just in case they contain something that should cause freezing. But that means we need to do the same for `proper_bodies`. 3.d

Another reason for bodies to cause freezing, there could be an added implementation burden if an entity declared in an enclosing `declarative_part` is frozen within a nested body, since some compilers look at bodies after looking at the containing `declarative_part`. 3.e

{AI05-0177-1} Note that “body” includes `null_procedure_declarations` and `expression_function_declarations` when those are used as completions, as well as `entry_bodys` (see 3.11.1). These all cause freezing, along with `proper_bodys` and `body_stubs`. 3.f/3

{8652/0046} {AI95-00106-01} A construct that (explicitly or implicitly) references an entity can cause the *freezing* of the entity, as defined by subsequent paragraphs. At the place where a construct causes freezing, each name, expression, `implicit_dereference`[, or `range`] within the construct causes freezing: 4/1

Ramification: Note that in the sense of this paragraph, a `subtype_mark` “references” the denoted subtype, but not the type. 4.a

- {AI05-0213-1} The occurrence of a `generic_instantiation` causes freezing, except that a `name` which is a generic actual parameter whose corresponding generic formal parameter is a formal incomplete type (see 12.5.1) does not cause freezing. In addition, if a parameter of the instantiation is defaulted, the `default_expression` or `default_name` for that parameter causes freezing. 5/3

Ramification: {AI05-0213-1} Thus, an actual parameter corresponding to a formal incomplete type parameter may denote an incomplete or private type which is not completely defined at the point of the `generic_instantiation`. 5.a/3

- The occurrence of an `object_declaration` that has no corresponding completion causes freezing. 6

Ramification: Note that this does not include a `formal_object_declaration`. 6.a

- The declaration of a record extension causes freezing of the parent subtype. 7

Ramification: This combined with another rule specifying that primitive subprogram declarations shall precede freezing ensures that all descendants of a tagged type implement all of its dispatching operations. 7.a

{AI95-00251-01} The declaration of a private extension does not cause freezing. The freezing is deferred until the full type declaration, which will necessarily be for a record extension, task, or protected type (the latter only for a limited private extension derived from an interface). 7.b/2

- 7.1/2 • *{AI95-00251-01}* The declaration of a record extension, interface type, task unit, or protected unit causes freezing of any progenitor types specified in the declaration.
- 7.b.1/2 **Reason:** This rule has the same purpose as the one above: ensuring that all descendants of an interface tagged type implement all of its dispatching operations. As with the previous rule, a private extension does not freeze its progenitors; the full type declaration (which must have the same progenitors) will do that.
- 7.b.2/2 **Ramification:** An interface type can be a parent as well as a progenitor; these rules are similar so that the location of an interface in a record extension does not have an effect on the freezing of the interface type.
- 7.2/3 • *{AI05-0183-1}* At the freezing point of the entity associated with an `aspect_specification`, any expressions or names within the `aspect_specification` cause freezing. Any static expressions within an `aspect_specification` also cause freezing at the end of the immediately enclosing declaration list.
- 8/3 *{8652/0046}* *{AI95-00106-01}* *{AI05-0177-1}* *{AI05-0183-1}* A static expression (other than within an `aspect_specification`) causes freezing where it occurs. An object name or nonstatic expression causes freezing where it occurs, unless the name or expression is part of a `default_expression`, a `default_name`, the expression of an expression function, an `aspect_specification`, or a per-object expression of a component's constraint, in which case, the freezing occurs later as part of another construct or at the freezing point of an associated entity.
- 8.1/3 *{8652/0046}* *{AI95-00106-01}* *{AI05-0019-1}* An implicit call freezes the same entities and profiles that would be frozen by an explicit call. This is true even if the implicit call is removed via implementation permissions.
- 8.2/1 *{8652/0046}* *{AI95-00106-01}* If an expression is implicitly converted to a type or subtype *T*, then at the place where the expression causes freezing, *T* is frozen.
- 9 The following rules define which entities are frozen at the place where a construct causes freezing:
- 10 • At the place where an expression causes freezing, the type of the expression is frozen, unless the expression is an enumeration literal used as a `discrete_choice` of the `array_aggregate` of an `enumeration_representation_clause`.
- 10.a **Reason:** We considered making enumeration literals never cause freezing, which would be more upward compatible, but examples like the variant record aggregate (`Discrim => Red, ...`) caused us to change our mind. Furthermore, an enumeration literal is a static expression, so the implementation should be allowed to represent it using its representation.
- 10.b **Ramification:** The following pathological example was legal in Ada 83, but is illegal in Ada 95:
- 10.c
- ```

package P1 is
 type T is private;
 package P2 is
 type Composite(D : Boolean) is
 record
 case D is
 when False => Cf : Integer;
 when True => Ct : T;
 end case;
 end record;
 end P2;
 X : Boolean := P2."="((False,1), (False,1));
 private
 type T is array(1..Func_Call) of Integer;
 end;

```
- 10.d In Ada 95, the declaration of `X` freezes `Composite` (because it contains an expression of that type), which in turn freezes `T` (even though `Ct` does not exist in this particular case). But type `T` is not completely defined at that point, violating the rule that a type shall be completely defined before it is frozen. In Ada 83, on the other hand, there is no occurrence of the name `T`, hence no forcing occurrence of `T`.
- 10.1/3 • *{AI05-0019-1}* *{AI05-0177-1}* At the place where a function call causes freezing, the profile of the function is frozen. Furthermore, if a parameter of the call is defaulted, the `default_expression` for that parameter causes freezing. If the function call is to an expression function, the expression of the expression function causes freezing.

- Reason:** {AI05-0019-1} This is the important rule for profile freezing: a call freezes the profile. That's because generating the call will need to know how the parameters are passed, and that will require knowing details of the types. Other uses of subprograms do not need to know about the parameters, and thus only freeze the subprogram, and not the profile. 10.e/3
- Note that we don't need to consider procedure or entry calls, since a body freezes everything that precedes it, and the end of a declarative part freezes everything in the declarative part. 10.f/3
- Ramification:** {AI05-0177-1} Freezing of the expression of an expression function only needs to be considered when the expression function is in the same compilation unit and there are no intervening bodies; the end of a declarative\_part or library package freezes everything in it, and a body freezes everything declared before it. 10.g/3
- {AI05-0019-1} {AI05-0177-1} {AI05-0296-1} At the place where a generic\_instantiation causes freezing of a callable entity, the profile of that entity is frozen unless the formal subprogram corresponding to the callable entity has a parameter or result of a formal untagged incomplete type; if the callable entity is an expression function, the expression of the expression function causes freezing. 10.2/3
 

**Reason:** Elaboration of the generic might call the actual for one of its formal subprograms, so we need to know the profile and (for an expression function) expression. 10.h/3
  - {AI05-0177-1} At the place where a use of the Access or Unchecked\_Access attribute whose prefix denotes an expression function causes freezing, the expression of the expression function causes freezing. 10.3/3
 

**Reason:** This is needed to avoid calls to unfrozen expressions. Consider: 10.i/3

```

package Pack is
 type Flub is range 0 .. 100;
 function Foo (A : in Natural) return Natural is
 (A + Flub'Size); -- The expression is not frozen here.
 type Bar is access function Foo (A : in Natural) return Natural;
 P : Bar := Foo'Access; -- (A)
 Val : Natural := P.all(5); -- (B)
end Pack;

```

If point (A) did not freeze the expression of Foo (which freezes Flub), then the call at point (B) would be depending on the aspects of the unfrozen type Flub. That would be bad. 10.j/3  
10.k/3  
10.l/3  
10.m/3  
10.n/3  
10.o/3  
10.p/3
  - At the place where a name causes freezing, the entity denoted by the name is frozen, unless the name is a prefix of an expanded name; at the place where an object name causes freezing, the nominal subtype associated with the name is frozen. 11
 

**Ramification:** {AI95-00114-01} This only matters in the presence of deferred constants or access types; an object\_declaration other than a deferred constant declaration causes freezing of the nominal subtype, plus all component junk. 11.a/2

*This paragraph was deleted. {8652/0046} {AI95-00106-01}* 11.b/1
  - {8652/0046} {AI95-00106-01} At the place where an implicit\_dereference causes freezing, the nominal subtype associated with the implicit\_dereference is frozen. 11.1/1
 

**Discussion:** This rule ensures that X.D freezes the same entities that X.all.D does. Note that an implicit\_dereference is neither a name nor expression by itself, so it isn't covered by other rules. 11.c/2
  - [ At the place where a range causes freezing, the type of the range is frozen.] 12
 

**Proof:** This is consequence of the facts that expressions freeze their type, and the Range attribute is defined to be equivalent to a pair of expressions separated by "...". 12.a
  - At the place where an allocator causes freezing, the designated subtype of its type is frozen. If the type of the allocator is a derived type, then all ancestor types are also frozen. 13
 

**Ramification:** Allocators also freeze the named subtype, as a consequence of other rules. 13.a

The ancestor types are frozen to prevent things like this: 13.b

```

type Pool_Ptr is access System.Storage_Pools.Root_Storage_Pool'Class;
function F return Pool_Ptr;

```

13.c

```

13.d package P is
 type A1 is access Boolean;
 type A2 is new A1;
 type A3 is new A2;
 X : A3 := new Boolean; -- Don't know what pool yet!
 for A1'Storage_Pool use F.all;
 end P;

```

13.e This is necessary because derived access types share their parent's pool.

- 14/3 • *{AI05-0019-1}* At the place where a profile is frozen, each subtype of the profile is frozen. If the corresponding callable entity is a member of an entry family, the index subtype of the family is frozen.

14.a/3 *This paragraph was deleted.*

- 15 • At the place where a subtype is frozen, its type is frozen. At the place where a type is frozen, any expressions or names within the full type definition cause freezing; the first subtype, and any component subtypes, index subtypes, and parent subtype of the type are frozen as well. For a specific tagged type, the corresponding class-wide type is frozen as well. For a class-wide type, the corresponding specific type is frozen as well.

15.a **Ramification:** Freezing a type needs to freeze its first subtype in order to preserve the property that the subtype-specific aspects of statically matching subtypes are the same.

15.b Freezing an access type does not freeze its designated subtype.

- 15.1/3 • *{AI95-00341-01}* *{AI05-0019-1}* At the place where a specific tagged type is frozen, the primitive subprograms of the type are frozen. At the place where a type is frozen, any subprogram named in an `attribute_definition_clause` for the type is frozen.

15.c/2 **Reason:** We have a language design principle that all of the details of a specific tagged type are known at its freezing point. But that is only true if the primitive subprograms are frozen at this point as well. Late changes of `Import` and `address clauses` violate the principle.

15.d/2 **Implementation Note:** This rule means that no implicit call to `Initialize` or `Adjust` can freeze a subprogram (the type and thus subprograms would have been frozen at worst at the same point).

15.e/3 **Discussion:** *{AI05-0019-1}* The second sentence is the rule that makes it possible to check that only subprograms with convention `Ada` are specified in `attribute_definition_clauses` without jumping through hoops.

#### *Legality Rules*

16 [The explicit declaration of a primitive subprogram of a tagged type shall occur before the type is frozen (see 3.9.2).]

16.a **Reason:** This rule is needed because (1) we don't want people dispatching to things that haven't been declared yet, and (2) we want to allow tagged type descriptors to be static (allocated statically, and initialized to link-time-known symbols). Suppose `T2` inherits primitive `P` from `T1`, and then overrides `P`. Suppose `P` is called *before* the declaration of the overriding `P`. What should it dispatch to? If the answer is the new `P`, we've violated the first principle above. If the answer is the old `P`, we've violated the second principle. (A call to the new one necessarily raises `Program_Error`, but that's beside the point.)

16.b Note that a call upon a dispatching operation of type `T` will freeze `T`.

16.c We considered applying this rule to all derived types, for uniformity. However, that would be upward incompatible, so we rejected the idea. As in Ada 83, for an untagged type, the above call upon `P` will call the old `P` (which is arguably confusing).

16.d/3 **To be honest:** *{AI05-0222-1}* This rule only applies to "original" declarations and not to the completion of a primitive subprogram, even though a completion is technically an explicit declaration, and it may declare a primitive subprogram.

17 [A type shall be completely defined before it is frozen (see 3.11.1 and 7.3).]

18 [The completion of a deferred constant declaration shall occur before the constant is frozen (see 7.4).]

18.a/3 **Proof:** *{AI95-00114-01}* *{AI05-0299-1}* The above Legality Rules are stated "officially" in the referenced subclauses.

19/1 *{8652/0009}* *{AI95-00137-01}* An operational or representation item that directly specifies an aspect of an entity shall appear before the entity is frozen (see 13.1).

- Discussion:** {8652/0009} {AI95-00137-01} From RM83-13.1(7). The wording here forbids freezing within the `aspect_clause` itself, which was not true of the Ada 83 wording. The wording of this rule is carefully written to work properly for type-related representation items. For example, an `enumeration_representation_clause` is illegal after the type is frozen, even though the `_clause` refers to the first subtype. 19.a/1
- {AI95-00114-01} The above Legality Rule is stated for types and subtypes in 13.1, but the rule here covers all other entities as well. 19.a.1/2
- This paragraph was deleted.* {AI95-00114-01} 19.b/2
- Discussion:** Here's an example that illustrates when freezing occurs in the presence of defaults: 19.c
- ```

type T is ...;
function F return T;
type R is
  record
    C : T := F;
    D : Boolean := F = F;
  end record;
X : R;

```
- 19.d
- Since the elaboration of R's declaration does not allocate component C, there is no need to freeze C's subtype at that place. Similarly, since the elaboration of R does not evaluate the `default_expression` "F = F", there is no need to freeze the types involved at that point. However, the declaration of X *does* need to freeze these things. Note that even if component C did not exist, the elaboration of the declaration of X would still need information about T — even though D is not of type T, its `default_expression` requires that information. 19.e
- Ramification:** {AI05-0299-1} Although we define freezing in terms of the program text as a whole (i.e. after applying the rules of Clause 10), the freezing rules actually have no effect beyond compilation unit boundaries. 19.f/3
- Reason:** {AI05-0299-1} That is important, because Clause 10 allows some implementation definedness in the order of things, and we don't want the freezing rules to be implementation defined. 19.g/3
- Ramification:** These rules also have no effect in `statements` — they only apply within a `single_declarative_part`, `package_specification`, `task_definition`, `protected_definition`, or `protected_body`. 19.h
- Implementation Note:** An implementation may choose to generate code for `default_expressions` and `default_names` in line at the place of use. Alternatively, an implementation may choose to generate thunks (subprograms implicitly generated by the compiler) for evaluation of defaults. Thunk generation cannot, in general, be done at the place of the declaration that includes the default. Instead, they can be generated at the first freezing point of the type(s) involved. (It is impossible to write a purely one-pass Ada compiler, for various reasons. This is one of them — the compiler needs to store a representation of defaults in its symbol table, and then walk that representation later, no earlier than the first freezing point.) 19.i
- In implementation terms, the linear elaboration model can be thought of as preventing uninitialized dope. For example, the implementation might generate dope to contain the size of a private type. This dope is initialized at the place where the type becomes completely defined. It cannot be initialized earlier, because of the order-of-elaboration rules. The freezing rules prevent elaboration of earlier declarations from accessing the size dope for a private type before it is initialized. 19.j
- 2.8 overrides the freezing rules in the case of unrecognized pragmas. 19.k
- {8652/0009} {AI95-00137-01} An `aspect_clause` for an entity should most certainly *not* be a freezing point for the entity. 19.l/1

Dynamic Semantics

- {AI95-00279-01} The tag (see 3.9) of a tagged type T is created at the point where T is frozen. 20/2

Incompatibilities With Ada 83

- RM83 defines a forcing occurrence of a type as follows: "A forcing occurrence is any occurrence [of the name of the type, subtypes of the type, or types or subtypes with subcomponents of the type] other than in a type or subtype declaration, a subprogram specification, an entry declaration, a deferred constant declaration, a `pragma`, or a `representation_clause` for the type itself. In any case, an occurrence within an expression is always forcing." 20.a
- It seems like the wording allows things like this: 20.b
- ```

type A is array(Integer range 1..10) of Boolean;
subtype S is Integer range A'Range;
-- not forcing for A

```
- 20.c
- Occurrences within `pragmas` can cause freezing in Ada 95. (Since such `pragmas` are ignored in Ada 83, this will probably fix more bugs than it causes.) 20.d

*Extensions to Ada 83*

20.e In Ada 95, `generic_formal_parameter_declarations` do not normally freeze the entities from which they are defined. For example:

```
20.f package Outer is
 type T is tagged limited private;
 generic
 type T2 is
 new T with private; -- Does not freeze T
 -- in Ada 95.
 package Inner is
 ...
 end Inner;
 private
 type T is ...;
 end Outer;
```

20.g This is important for the usability of generics. The above example uses the Ada 95 feature of formal derived types. Examples using the kinds of formal parameters already allowed in Ada 83 are well known. See, for example, comments 83-00627 and 83-00688. The extensive use expected for formal derived types makes this issue even more compelling than described by those comments. Unfortunately, we are unable to solve the problem that `explicit_generic_actual_parameters` cause freezing, even though a package equivalent to the instance would not cause freezing. This is primarily because such an equivalent package would have its body in the body of the containing program unit, whereas an instance has its body right there.

*Wording Changes from Ada 83*

20.h The concept of freezing is based on Ada 83's concept of “forcing occurrences.” The first freezing point of an entity corresponds roughly to the place of the first forcing occurrence, in Ada 83 terms. The reason for changing the terminology is that the new rules do not refer to any particular “occurrence” of a name of an entity. Instead, we refer to “uses” of an entity, which are sometimes implicit.

20.i In Ada 83, forcing occurrences were used only in rules about `representation_clauses`. We have expanded the concept to cover private types, because the rules stated in RM83-7.4.1(4) are almost identical to the forcing occurrence rules.

20.j The Ada 83 rules are changed in Ada 95 for the following reasons:

- 20.k • The Ada 83 rules do not work right for subtype-specific aspects. In an earlier version of Ada 9X, we considered allowing representation items to apply to subtypes other than the first subtype. This was part of the reason for changing the Ada 83 rules. However, now that we have dropped that functionality, we still need the rules to be different from the Ada 83 rules.
- 20.l • The Ada 83 rules do not achieve the intended effect. In Ada 83, either with or without the AIs, it is possible to force the compiler to generate code that references uninitialized dope, or force it to detect erroneous access and exception raising at compile time.
- 20.m • It was a goal of Ada 83 to avoid uninitialized access values. However, in the case of deferred constants, this goal was not achieved.
- 20.n • The Ada 83 rules are not only too weak — they are also too strong. They allow loopholes (as described above), but they also prevent certain kinds of `default_expressions` that are harmless, and certain kinds of `generic_declarations` that are both harmless and very useful.
- 20.o/2 • *{AI95-00114-01}* Ada 83 had a case where an `aspect_clause` had a strong effect on the semantics of the program — 'Small. This caused certain semantic anomalies. There are more cases in Ada 95, because the `attribute_definition_clause` has been generalized.

*Incompatibilities With Ada 95*

20.p/2 *{8652/0046}* *{AI95-00106-01}* *{AI95-00341-01}* **Corrigendum:** Various freezing rules were added to fix holes in the rules. Most importantly, implicit calls are now freezing, which make some representation clauses illegal in Ada 2005 that were legal (but dubious) in Ada 95. **Amendment Correction:** Similarly, the primitive subprograms of a specific tagged type are frozen when the type is frozen, preventing dubious convention changes (and address clauses) after the freezing point. In both cases, the code is dubious and the workaround is easy.

*Wording Changes from Ada 95*

20.q/2 *{8652/0009}* *{AI95-00137-01}* **Corrigendum:** Added wording to specify that both operational and representation attributes must be specified before the type is frozen.

20.r/2 *{AI95-00251-01}* Added wording that declaring a specific descendant of an interface type freezes the interface type.

20.s/2 *{AI95-00279-01}* Added wording that defines when a tag is created for a type (at the freezing point of the type). This is used to specify checking for uncreated tags (see 3.9).

*Incompatibilities With Ada 2005*

{AI05-0019-1} **Correction:** Separated the freezing of the profile from the rest of a subprogram, in order to reduce the impact of the Ada 95 incompatibility noted above. (The effects were much more limiting than expected.) 20.t/3

*Wording Changes from Ada 2005*

{AI05-0017-1} **Correction:** Reworded so that incomplete types with a deferred completion aren't prematurely frozen. 20.u/3

{AI05-0177-1} Added freezing rules for expression functions; these are frozen at the point of call, not the point of declaration, like default expressions. 20.v/3

{AI05-0183-1} Added freezing rules for `aspect_specifications`; these are frozen at the freezing point of the associated entity, not the point of declaration. 20.w/3

{AI05-0213-1} Added freezing rules for formal incomplete types; the corresponding actual is not frozen. 20.x/3

# The Standard Libraries

# Annex A

## (normative)

### Predefined Language Environment

[ This Annex contains the specifications of library units that shall be provided by every implementation. 1  
There are three root library units: Ada, Interfaces, and System; other library units are children of these:]

{8652/0047} {AI95-00081-01} {AI95-00424-01} {AI05-0001-1} {AI05-0049-1} {AI05-0069-1} {AI05- 2/3  
0111-3} {AI05-0136-1} {AI05-0137-1} {AI05-0166-1} {AI05-0168-1}

- 2.a **Discussion:** In running text, we generally leave out the “Ada.” when referring to a child of Ada.
- 2.b **Reason:** We had no strict rule for which of Ada, Interfaces, or System should be the parent of a given library unit. However, we have tried to place as many things as possible under Ada, except that interfacing is a separate category, and we have tried to place library units whose use is highly nonportable under System.

*Implementation Requirements*

- 3/2 *{AI95-00434-01}* The implementation shall ensure that each language-defined subprogram is reentrant in the sense that concurrent calls on the same subprogram perform as specified, so long as all parameters that could be passed by reference denote nonoverlapping objects.
- 3.a **Ramification:** For example, simultaneous calls to Text\_IO.Put will work properly, so long as they are going to two different files. On the other hand, simultaneous output to the same file constitutes erroneous use of shared variables.
- 3.b **To be honest:** Here, “language defined subprogram” means a language defined library subprogram, a subprogram declared in the visible part of a language defined library package, an instance of a language defined generic library subprogram, or a subprogram declared in the visible part of an instance of a language defined generic library package.
- 3.c **Ramification:** The rule implies that any data local to the private part or body of the package has to be somehow protected against simultaneous access.
- 3.1/3 *{AI05-0048-1}* If a descendant of a language-defined tagged type is declared, the implementation shall ensure that each inherited language-defined subprogram behaves as described in this International Standard. In particular, overriding a language-defined subprogram shall not alter the effect of any inherited language-defined subprogram.

- Reason:** This means that internally the implementation must not do redispaching unless it is required by the Standard. So when we say that some subprogram *Bar* is equivalent to *Foo*, overriding *Foo* for a derived type doesn't change the semantics of *Bar*, and in particular it means that *Bar* may no longer be equivalent to *Foo*. The word “equivalent” is always a bit of a lie anyway. 3.d/3
- Implementation Permissions*
- The implementation may restrict the replacement of language-defined compilation units. The implementation may restrict children of language-defined library units (other than *Standard*). 4
- Ramification:** For example, the implementation may say, “you cannot compile a library unit called *System*” or “you cannot compile a child of package *System*” or “if you compile a library unit called *System*, it has to be a package, and it has to contain at least the following declarations: ...”. 4.a
- Wording Changes from Ada 83*
- Many of Ada 83's language-defined library units are now children of *Ada* or *System*. For upward compatibility, these are renamed as root library units (see J.1). 4.b
- The order and lettering of the annexes has been changed. 4.c
- Wording Changes from Ada 95*
- {8652/0047} {AI95-00081-01} **Corrigendum:** Units missing from the list of predefined units were added. 4.d/2
- {AI95-00424-01} Added new units to the list of predefined units. 4.e/2
- Wording Changes from Ada 2005*
- {AI05-0048-1} **Correction:** Added wording to ban redispaching unless it is explicitly required, in order to safeguard portability when overriding language-defined routines. 4.f/3
- {AI05-0060-1} {AI05-0206-1} **Correction:** Added a permission to omit pragma *Remote\_Types* from language-defined units if Annex E is not supported. This was later removed, as a better method of supporting the reason is now available. Note that this requires all implementations to provide minimal support for the *Remote\_Types* categorization even if Annex E is not supported; being unable to compile language-defined units is not allowed. 4.g/3
- {AI05-0001-1} {AI05-0049-1} {AI05-0069-1} {AI05-0111-3} {AI05-0136-1} {AI05-0137-1} {AI05-0166-1} {AI05-0168-1} Added various new units to the list of predefined units. 4.h/3

## A.1 The Package Standard

- {AI05-0299-1} This subclause outlines the specification of the package *Standard* containing all predefined identifiers in the language. The corresponding package body is not specified by the language. 1/3
- The operators that are predefined for the types declared in the package *Standard* are given in comments since they are implicitly declared. Italics are used for pseudo-names of anonymous types (such as *root\_real*) and for undefined information (such as *implementation-defined*). 2
- Ramification:** All of the predefined operators are of convention *Intrinsic*. 2.a
- Static Semantics*
- The library package *Standard* has the following declaration: 3
- Implementation defined:** The names and characteristics of the numeric subtypes declared in the visible part of package *Standard*. 3.a
- ```
package Standard is
  pragma Pure(Standard);
  type Boolean is (False, True);
```
- 4 5

```

6      -- The predefined relational operators for this type are as follows:
7/1    {8652/0028} {AI95-00145-01}    -- function "="    (Left, Right : Boolean'Base)
return Boolean;
      -- function "/=" (Left, Right : Boolean'Base) return Boolean;
      -- function "<" (Left, Right : Boolean'Base) return Boolean;
      -- function "<=" (Left, Right : Boolean'Base) return Boolean;
      -- function ">" (Left, Right : Boolean'Base) return Boolean;
      -- function ">=" (Left, Right : Boolean'Base) return Boolean;

<p>Standard has no private part.</p> <p>Reason: This is important for portability. All library packages are children of Standard, and if Standard had a private part then it would be visible to all of them.</p> <p>{AI95-00285-01} In each of the types Character, Wide_Character, and Wide_Wide_Character, the character literals for the space character (position 32) and the non-breaking space character (position 160) correspond to different values. Unless indicated otherwise, each occurrence of the character literal ' ' in this International Standard refers to the space character. Similarly, the character literals for hyphen (position 45) and soft hyphen (position 173) correspond to different values. Unless indicated otherwise, each occurrence of the character literal '-' in this International Standard refers to the hyphen character.</p>	<p>48</p> <p>48.a</p> <p>49/2</p>
<p style="text-align: center;"><i>Dynamic Semantics</i></p> <p>Elaboration of the body of Standard has no effect.</p>	<p>50</p>

50.a **Discussion:** Note that the language does not define where this body appears in the environment `declarative_part` — see 10, “Program Structure and Compilation Issues”.

Implementation Permissions

51 An implementation may provide additional predefined integer types and additional predefined floating point types. Not all of these types need have names.

51.a **To be honest:** An implementation may add representation items to package `Standard`, for example to specify the internal codes of type `Boolean`, or the Small of type `Duration`.

Implementation Advice

52 If an implementation provides additional named predefined integer types, then the names should end with “Integer” as in “`Long_Integer`”. If an implementation provides additional named predefined floating point types, then the names should end with “Float” as in “`Long_Float`”.

52.a/2 **Implementation Advice:** If an implementation provides additional named predefined integer types, then the names should end with “Integer”. If an implementation provides additional named predefined floating point types, then the names should end with “Float”.

NOTES

53 1 Certain aspects of the predefined entities cannot be completely described in the language itself. For example, although the enumeration type `Boolean` can be written showing the two enumeration literals `False` and `True`, the short-circuit control forms cannot be expressed in the language.

54 2 As explained in 8.1, “Declarative Region” and 10.1.4, “The Compilation Process”, the declarative region of the package `Standard` encloses every library unit and consequently the main subprogram; the declaration of every library unit is assumed to occur within this declarative region. `Library_items` are assumed to be ordered in such a way that there are no forward semantic dependences. However, as explained in 8.3, “Visibility”, the only library units that are visible within a given compilation unit are the library units named by all `with_clauses` that apply to the given unit, and moreover, within the declarative region of a given library unit, that library unit itself.

55 3 If all `block_statements` of a program are named, then the name of each program unit can always be written as an expanded name starting with `Standard` (unless `Standard` is itself hidden). The name of a library unit cannot be a homograph of a name (such as `Integer`) that is already declared in `Standard`.

56 4 The exception `Standard.Numeric_Error` is defined in J.6.

56.a **Discussion:** The declaration of `Natural` needs to appear between the declaration of `Integer` and the (implicit) declaration of the “`***`” operator for `Integer`, because a formal parameter of “`***`” is of subtype `Natural`. This would be impossible in normal code, because the implicit declarations for a type occur immediately after the type declaration, with no possibility of intervening explicit declarations. But we’re in `Standard`, and `Standard` is somewhat magic anyway.

56.b Using `Natural` as the subtype of the formal of “`***`” seems natural; it would be silly to have a textual rule about `Constraint_Error` being raised when there is a perfectly good subtype that means just that. Furthermore, by not using `Integer` for that formal, it helps remind the reader that the exponent remains `Natural` even when the left operand is replaced with the derivative of `Integer`. It doesn’t logically imply that, but it’s still useful as a reminder.

56.c In any case, declaring these general-purpose subtypes of `Integer` close to `Integer` seems more readable than declaring them much later.

Extensions to Ada 83

56.d Package `Standard` is declared to be pure.

56.e **Discussion:** The introduction of the types `Wide_Character` and `Wide_String` is not an Ada 95 extension to Ada 83, since ISO WG9 has approved these as an authorized extension of the original Ada 83 standard that is part of that standard.

Wording Changes from Ada 83

56.f `Numeric_Error` is made obsolescent.

56.g The declarations of `Natural` and `Positive` are moved to just after the declaration of `Integer`, so that “`***`” can refer to `Natural` without a forward reference. There’s no real need to move `Positive`, too — it just came along for the ride.

Extensions to Ada 95

- {AI95-00285-01} Types `Wide_Wide_Character` and `Wide_Wide_String` are new. 56.h/2
- Discussion:** The inconsistencies associated with these types are documented in 3.5.2 and 3.6.3. 56.i/2
- {AI95-00230-01} Type `universal_access` and the equality operations for it are new. 56.j/2

Wording Changes from Ada 95

- {8652/0028} {AI95-00145-01} **Corrigendum:** Corrected the parameter type for the Boolean operators declared in Standard.. 56.k/2

Wording Changes from Ada 2005

- {AI05-0181-1} **Correction:** Since `soft_hyphen` (position 173) is defined to be nongraphic, gave it a name. 56.l/3
- Discussion:** The inconsistencies associated with this change are documented in 3.5. 56.m/3

A.2 The Package Ada

Static Semantics

The following language-defined library package exists: 1

```
package Ada is 2
  pragma Pure (Ada);
end Ada;
```

Ada serves as the parent of most of the other language-defined library units; its declaration is empty (except for the `pragma Pure`). 3

Legality Rules

In the standard mode, it is illegal to compile a child of package Ada. 4

Reason: The intention is that mentioning, say, `Ada.Text_IO` in a `with_clause` is guaranteed (at least in the standard mode) to refer to the standard version of `Ada.Text_IO`. The user can compile a root library unit `Text_IO` that has no relation to the standard version of `Text_IO`. 4.a

Ramification: Note that Ada can have non-language-defined grandchildren, assuming the implementation allows it. Also, packages `System` and `Interfaces` can have children, assuming the implementation allows it. 4.b

Implementation Note: An implementation will typically support a nonstandard mode in which compiling the language defined library units is allowed. Whether or not this mode is made available to users is up to the implementer. 4.c

An implementation could theoretically have private children of Ada, since that would be semantically neutral. However, a programmer cannot compile such a library unit. 4.d

Extensions to Ada 83

- {AI05-0299-1} This subclause is new to Ada 95. 4.e/3

A.3 Character Handling

{AI95-00285-01} {AI05-0243-1} {AI05-0299-1} This subclause presents the packages related to character processing: an empty declared pure package `Characters` and child packages `Characters.Handling` and `Characters.Latin_1`. The package `Characters.Handling` provides classification and conversion functions for `Character` data, and some simple functions for dealing with `Wide_Character` and `Wide_Wide_Character` data. The child package `Characters.Latin_1` declares a set of constants initialized to values of type `Character`. 1/3

Extensions to Ada 83

- {AI05-0299-1} This subclause is new to Ada 95. 1.a/3

Wording Changes from Ada 95

- 1.b/2 {AI95-00285-01} Included Wide_Wide_Character in this description; the individual changes are documented as extensions as needed.

A.3.1 The Packages Characters, Wide_Characters, and Wide_Wide_Characters

Static Semantics

- 1 The library package Characters has the following declaration:

```
2 package Ada.Characters is
  pragma Pure (Characters);
  end Ada.Characters;
```

- 3/2 {AI95-00395-01} The library package Wide_Characters has the following declaration:

```
4/2 package Ada.Wide_Characters is
  pragma Pure (Wide_Characters);
  end Ada.Wide_Characters;
```

- 5/2 {AI95-00395-01} The library package Wide_Wide_Characters has the following declaration:

```
6/2 package Ada.Wide_Wide_Characters is
  pragma Pure (Wide_Wide_Characters);
  end Ada.Wide_Wide_Characters;
```

Implementation Advice

- 7/3 {AI95-00395-01} {AI05-0185-1} If an implementation chooses to provide implementation-defined operations on Wide_Character or Wide_String (such as collating and sorting, etc.) it should do so by providing child units of Wide_Characters. Similarly if it chooses to provide implementation-defined operations on Wide_Wide_Character or Wide_Wide_String it should do so by providing child units of Wide_Wide_Characters.

- 7.a/2 **Implementation Advice:** Implementation-defined operations on Wide_Character, Wide_String, Wide_Wide_Character, and Wide_Wide_String should be child units of Wide_Characters or Wide_Wide_Characters.

Extensions to Ada 95

- 7.b/2 {AI95-00395-01} The packages Wide_Characters and Wide_Wide_Characters are new.

A.3.2 The Package Characters.Handling

Static Semantics

- 1 The library package Characters.Handling has the following declaration:

```
2/2 {AI95-00362-01} {AI95-00395-01} with Ada.Characters.Conversions;
  package Ada.Characters.Handling is
    pragma Pure (Handling);
```

```

--Character classification functions

return ISO_646;
function To_ISO_646 (Item : in String; 12
Substitute : in ISO_646 := ' ')
return String;
{AI95-00285-01} {AI95-00395-01} -- The functions Is_Character, Is_String, To_Character, To_String, 13/2
To_Wide_Character,
-- and To_Wide_String are obsolescent; see J.14.
Paragraphs 14 through 18 were deleted.
end Ada.Characters.Handling; 19
Discussion: {AI95-00395-01} The with_clause for Ada.Characters.Conversions is needed for the definition of the 19.a/2
obsolescent functions (see J.14). It would be odd to put this clause into J.14 as it was not present in Ada 95, and
with_clauses are semantically neutral to clients anyway.

```

In the description below for each function that returns a Boolean result, the effect is described in terms of the conditions under which the value True is returned. If these conditions are not met, then the function returns False. 20

Each of the following classification functions has a formal Character parameter, Item, and returns a Boolean result. 21

Is_Control 22
True if Item is a control character. A *control character* is a character whose position is in one of the ranges 0..31 or 127..159.

Is_Graphic 23
True if Item is a graphic character. A *graphic character* is a character whose position is in one of the ranges 32..126 or 160..255.

- 24 `Is_Letter` True if Item is a letter. A *letter* is a character that is in one of the ranges 'A'..'Z' or 'a'..'z', or whose position is in one of the ranges 192..214, 216..246, or 248..255.
- 25 `Is_Lower` True if Item is a lower-case letter. A *lower-case letter* is a character that is in the range 'a'..'z', or whose position is in one of the ranges 223..246 or 248..255.
- 26 `Is_Upper` True if Item is an upper-case letter. An *upper-case letter* is a character that is in the range 'A'..'Z' or whose position is in one of the ranges 192..214 or 216.. 222.
- 27 `Is_Basic` True if Item is a basic letter. A *basic letter* is a character that is in one of the ranges 'A'..'Z' and 'a'..'z', or that is one of the following: 'Æ', 'æ', 'Ð', 'ð', 'Þ', 'þ', or 'ß'.
- 28 `Is_Digit` True if Item is a decimal digit. A *decimal digit* is a character in the range '0'..'9'.
- 29 `Is_Decimal_Digit`
A renaming of `Is_Digit`.
- 30 `Is_Hexadecimal_Digit`
True if Item is a hexadecimal digit. A *hexadecimal digit* is a character that is either a decimal digit or that is in one of the ranges 'A' .. 'F' or 'a' .. 'f'.
- 31 `Is_Alphanumeric`
True if Item is an alphanumeric character. An *alphanumeric character* is a character that is either a letter or a decimal digit.
- 32 `Is_Special`
True if Item is a special graphic character. A *special graphic character* is a graphic character that is not alphanumeric.
- 32.1/3 `{AI05-0185-1} Is_Line_Terminator`
True if Item is a character with position 10 .. 13 (Line_Feed, Line_Tabulation, Form_Feed, Carriage_Return) or 133 (Next_Line).
- 32.2/3 `{AI05-0185-1} Is_Mark`
Never True (no value of type Character has categories Mark, Non-Spacing or Mark, Spacing Combining).
- 32.3/3 `{AI05-0185-1} Is_Other_Format`
True if Item is a character with position 173 (Soft_Hyphen).
- 32.4/3 `{AI05-0185-1} Is_Punctuation_Connector`
True if Item is a character with position 95 ('_', known as Low_Line or Underscore).
- 32.5/3 `{AI05-0185-1} Is_Space`
True if Item is a character with position 32 (' ') or 160 (No_Break_Space).
- 33 Each of the names `To_Lower`, `To_Upper`, and `To_Basic` refers to two functions: one that converts from Character to Character, and the other that converts from String to String. The result of each Character-to-Character function is described below, in terms of the conversion applied to Item, its formal Character parameter. The result of each String-to-String conversion is obtained by applying to each element of the function's String parameter the corresponding Character-to-Character conversion; the result is the null String if the value of the formal parameter is the null String. The lower bound of the result String is 1.
- 34 `To_Lower` Returns the corresponding lower-case value for Item if `Is_Upper(Item)`, and returns Item otherwise.
- 35 `To_Upper` Returns the corresponding upper-case value for Item if `Is_Lower(Item)` and Item has an upper-case form, and returns Item otherwise. The lower case letters 'ß' and 'ÿ' do not have upper case forms.
- 36 `To_Basic` Returns the letter corresponding to Item but with no diacritical mark, if Item is a letter but not a basic letter; returns Item otherwise.

The following set of functions test for membership in the ISO 646 character range, or convert between ISO 646 and Character.	37
<code>Is_ISO_646</code>	38
The function whose formal parameter, <code>Item</code> , is of type <code>Character</code> returns <code>True</code> if <code>Item</code> is in the subtype <code>ISO_646</code> .	
<code>Is_ISO_646</code>	39
The function whose formal parameter, <code>Item</code> , is of type <code>String</code> returns <code>True</code> if <code>Is_ISO_646(Item(I))</code> is <code>True</code> for each <code>I</code> in <code>Item'Range</code> .	
<code>To_ISO_646</code>	40
The function whose first formal parameter, <code>Item</code> , is of type <code>Character</code> returns <code>Item</code> if <code>Is_ISO_646(Item)</code> , and returns the Substitute ISO_646 character otherwise.	
<code>To_ISO_646</code>	41
The function whose first formal parameter, <code>Item</code> , is of type <code>String</code> returns the <code>String</code> whose <code>Range</code> is <code>1..Item'Length</code> and each of whose elements is given by <code>To_ISO_646</code> of the corresponding element in <code>Item</code> .	
<i>Paragraphs 42 through 49 were deleted.</i>	
NOTES	
5 A basic letter is a letter without a diacritical mark.	50
6 Except for the hexadecimal digits, basic letters, and ISO_646 characters, the categories identified in the classification functions form a strict hierarchy:	51
— Control characters	52
— Graphic characters	53
— Alphanumeric characters	54
— Letters	55
— Upper-case letters	56
— Lower-case letters	57
— Decimal digits	58
— Special graphic characters	59
Ramification: Thus each <code>Character</code> value is either a control character or a graphic character but not both; each graphic character is either an alphanumeric or special graphic but not both; each alphanumeric is either a letter or decimal digit but not both; each letter is either upper case or lower case but not both.	59.a
7 { <i>AI05-0114-1</i> } There are certain characters which are defined to be lower case letters by ISO 10646 and are therefore allowed in identifiers, but are not considered lower case letters by <code>Ada.Characters.Handling</code> .	60/3
Reason: This is to maintain runtime compatibility with the Ada 95 definitions of these functions. We don't list the exact characters involved because they're likely to change in future character set standards; the list for ISO 10646:2011 can be found in <i>AI05-0114-1</i> .	60.a/3
Ramification: No version of <code>Characters.Handling</code> is intended to do portable (Ada-version independent) manipulation of Ada identifiers. The classification given by <code>Wide_Characters.Handling</code> will be correct for the current implementation for Ada 2012 identifiers, but it might not be correct for a different implementation or version of Ada.	60.b/3
<i>Extensions to Ada 95</i>	
{ <i>AI95-00362-01</i> } <code>Characters.Handling</code> is now <code>Pure</code> , so it can be used in pure units.	60.c/2
<i>Incompatibilities With Ada 2005</i>	
{ <i>AI05-0185-1</i> } Added additional classification routines so that <code>Characters.Handling</code> has all of the routines available in <code>Wide_Characters.Handling</code> . If <code>Characters.Handling</code> is referenced in a <code>use_clause</code> , and an entity <i>E</i> with a <code>defining_identifier</code> that is the same as one of the new functions is defined in a package that is also referenced in a <code>use_clause</code> , the entity <i>E</i> may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur.	60.d/3

Wording Changes from Ada 95

- 60.e/2 {AI95-00285-01} {AI95-00395-01} The conversion functions are made obsolescent; a more complete set is available in Characters.Conversions — see A.3.4.
- 60.f/3 {AI95-00285-01} {AI05-0248-1} We no longer talk about localized character sets; these are a nonstandard mode, which is none of our business.

Wording Changes from Ada 2005

- 60.g/3 {AI05-0114-1} **Correction:** Added a note to clarify that these functions don't have any relationship to the characters allowed in identifiers.

A.3.3 The Package Characters.Latin_1

1 The package Characters.Latin_1 declares constants for characters in ISO 8859-1.

- 1.a **Reason:** The constants for the ISO 646 characters could have been declared as renamings of objects declared in package ASCII, as opposed to explicit constants. The main reason for explicit constants was for consistency of style with the upper-half constants, and to avoid emphasizing the package ASCII.

Static Semantics

2 The library package Characters.Latin_1 has the following declaration:

```

3  package Ada.Characters.Latin_1 is
4      pragma Pure(Latin_1);
5
6  -- Control characters:

end Ada.Characters.Latin_1;

```

Implementation Permissions

27 An implementation may provide additional packages as children of Ada.Characters, to declare names for the symbols of the local character set or other character sets.

Wording Changes from Ada 2005

27.a/3 {AI05-0181-1} **Correction:** Soft_Hyphen is not a graphic character, and thus a character literal for it is illegal. So we have to use the position value. This makes no semantic change to users of the constant.

A.3.4 The Package Characters.Conversions

Static Semantics

1/2 {AI95-00395-01} The library package Characters.Conversions has the following declaration:

```

2/2  package Ada.Characters.Conversions is
    pragma Pure(Conversions);

3/2  function Is_Character (Item : in Wide_Character)      return Boolean;
    function Is_String   (Item : in Wide_String)         return Boolean;
    function Is_Character (Item : in Wide_Wide_Character) return Boolean;
    function Is_String   (Item : in Wide_Wide_String)    return Boolean;
    function Is_Wide_Character (Item : in Wide_Wide_Character)
        return Boolean;
    function Is_Wide_String   (Item : in Wide_Wide_String)
        return Boolean;

```

```

function To_Wide_Character (Item : in Character) return Wide_Character;           4/2
function To_Wide_String   (Item : in String)   return Wide_String;
function To_Wide_Wide_Character (Item : in Character)
  return Wide_Wide_Character;
function To_Wide_Wide_String (Item : in String)
  return Wide_Wide_String;
function To_Wide_Wide_Character (Item : in Wide_Character)
  return Wide_Wide_Character;
function To_Wide_Wide_String   (Item : in Wide_String)
  return Wide_Wide_String;

function To_Character (Item      : in Wide_Character;
  Substitute : in Character := ' ')           5/2
  return Character;
function To_String   (Item      : in Wide_String;
  Substitute : in Character := ' ')
  return String;
function To_Character (Item :      in Wide_Wide_Character;
  Substitute : in Character := ' ')
  return Character;
function To_String   (Item :      in Wide_Wide_String;
  Substitute : in Character := ' ')
  return String;
function To_Wide_Character (Item :      in Wide_Wide_Character;
  Substitute : in Wide_Character := ' ')
  return Wide_Character;
function To_Wide_String   (Item :      in Wide_Wide_String;
  Substitute : in Wide_Character := ' ')
  return Wide_String;

end Ada.Characters.Conversions;           6/2
{AI95-00395-01} The functions in package Characters.Conversions test Wide_Wide_Character or 7/2
Wide_Character values for membership in Wide_Character or Character, or convert between
corresponding characters of Wide_Wide_Character, Wide_Character, and Character.

function Is_Character (Item : in Wide_Character) return Boolean;           8/2
  {AI95-00395-01} Returns True if Wide_Character'Pos(Item) <= Character'Pos(Character'Last). 9/2

function Is_Character (Item : in Wide_Wide_Character) return Boolean;       10/2
  {AI95-00395-01} Returns True if Wide_Wide_Character'Pos(Item) <= 11/2
  Character'Pos(Character'Last).

function Is_Wide_Character (Item : in Wide_Wide_Character) return Boolean;   12/2
  {AI95-00395-01} Returns True if Wide_Wide_Character'Pos(Item) <= 13/2
  Wide_Character'Pos(Wide_Character'Last).

function Is_String (Item : in Wide_String) return Boolean;                 14/2
function Is_String (Item : in Wide_Wide_String) return Boolean;
  {AI95-00395-01} Returns True if Is_Character(Item(I)) is True for each I in Item'Range. 15/2

function Is_Wide_String (Item : in Wide_Wide_String) return Boolean;       16/2
  {AI95-00395-01} Returns True if Is_Wide_Character(Item(I)) is True for each I in Item'Range. 17/2

function To_Character (Item :      in Wide_Character;
  Substitute : in Character := ' ') return Character;                       18/2
function To_Character (Item :      in Wide_Wide_Character;
  Substitute : in Character := ' ') return Character;
  {AI95-00395-01} Returns the Character corresponding to Item if Is_Character(Item), and returns 19/2
  the Substitute Character otherwise.

function To_Wide_Character (Item : in Character) return Wide_Character;     20/2

```

<i>{AI05-0185-1}</i> Returns <code>True</code> if the <code>Wide_Character</code> designated by <code>Item</code> is categorized as <code>letter_uppercase</code> ; otherwise returns <code>False</code> .	33/3

- 34/3 **function** Is_Digit (Item : Wide_Character) **return** Boolean;
- 35/3 {AI05-0185-1} Returns True if the Wide_Character designated by Item is categorized as number_decimal; otherwise returns False.
- 36/3 **function** Is_Hexadecimal_Digit (Item : Wide_Character) **return** Boolean;
- 37/3 {AI05-0185-1} Returns True if the Wide_Character designated by Item is categorized as number_decimal, or is in the range 'A' .. 'F' or 'a' .. 'f'; otherwise returns False.
- 38/3 **function** Is_Alphanumeric (Item : Wide_Character) **return** Boolean;
- 39/3 {AI05-0185-1} Returns True if the Wide_Character designated by Item is categorized as letter_uppercase, letter_lowercase, letter_titlecase, letter_modifier, letter_other, number_letter, or number_decimal; otherwise returns False.
- 40/3 **function** Is_Special (Item : Wide_Character) **return** Boolean;
- 41/3 {AI05-0185-1} Returns True if the Wide_Character designated by Item is categorized as graphic_character, but not categorized as letter_uppercase, letter_lowercase, letter_titlecase, letter_modifier, letter_other, number_letter, or number_decimal; otherwise returns False.
- 42/3 **function** Is_Line_Terminator (Item : Wide_Character) **return** Boolean;
- 43/3 {AI05-0185-1} Returns True if the Wide_Character designated by Item is categorized as separator_line or separator_paragraph, or if Item is a conventional line terminator character (Line_Feed, Line_Tabulation, Form_Feed, Carriage_Return, Next_Line); otherwise returns False.
- 44/3 **function** Is_Mark (Item : Wide_Character) **return** Boolean;
- 45/3 {AI05-0185-1} Returns True if the Wide_Character designated by Item is categorized as mark_non_spacing or mark_spacing_combining; otherwise returns False.
- 46/3 **function** Is_Other_Format (Item : Wide_Character) **return** Boolean;
- 47/3 {AI05-0185-1} Returns True if the Wide_Character designated by Item is categorized as other_format; otherwise returns False.
- 48/3 **function** Is_Punctuation_Connector (Item : Wide_Character) **return** Boolean;
- 49/3 {AI05-0185-1} Returns True if the Wide_Character designated by Item is categorized as punctuation_connector; otherwise returns False.
- 50/3 **function** Is_Space (Item : Wide_Character) **return** Boolean;
- 51/3 {AI05-0185-1} Returns True if the Wide_Character designated by Item is categorized as separator_space; otherwise returns False.
- 52/3 **function** Is_Graphic (Item : Wide_Character) **return** Boolean;
- 53/3 {AI05-0185-1} Returns True if the Wide_Character designated by Item is categorized as graphic_character; otherwise returns False.
- 54/3 **function** To_Lower (Item : Wide_Character) **return** Wide_Character;
- 55/3 {AI05-0185-1} {AI05-0266-1} {AI05-0299-1} Returns the Simple Lowercase Mapping as defined by documents referenced in the note in Clause 1 of ISO/IEC 10646:2011 of the Wide_Character designated by Item. If the Simple Lowercase Mapping does not exist for the Wide_Character designated by Item, then the value of Item is returned.
- 55.a/3 **Discussion:** The case mappings come from Unicode as ISO/IEC 10646:2011 does not include case mappings (but rather references the Unicode ones as above).

function To_Lower (Item : Wide_String) **return** Wide_String; 56/3

{AI05-0185-1} Returns the result of applying the To_Lower conversion to each Wide_Character element of the Wide_String designated by Item. The result is the null Wide_String if the value of the formal parameter is the null Wide_String. The lower bound of the result Wide_String is 1. 57/3

function To_Upper (Item : Wide_Character) **return** Wide_Character; 58/3

{AI05-0185-1} {AI05-0266-1} {AI05-0299-1} Returns the Simple Uppercase Mapping as defined by documents referenced in the note in Clause 1 of ISO/IEC 10646:2011 of the Wide_Character designated by Item. If the Simple Uppercase Mapping does not exist for the Wide_Character designated by Item, then the value of Item is returned. 59/3

function To_Upper (Item : Wide_String) **return** Wide_String; 60/3

{AI05-0185-1} Returns the result of applying the To_Upper conversion to each Wide_Character element of the Wide_String designated by Item. The result is the null Wide_String if the value of the formal parameter is the null Wide_String. The lower bound of the result Wide_String is 1. 61/3

Implementation Advice

{AI05-0266-1} The string returned by Character_Set_Version should include either “10646:” or “Unicode”. 62/3

Implementation Advice: The string returned by Wide_Characters.Handling.Character_Set_Version should include either “10646:” or “Unicode”. 62.a.1/3

Discussion: The intent is that the returned string include the year for 10646 (as in "10646:2011"), and the version number for Unicode (as in "Unicode 6.0"). We don't try to specify that further so we don't need to decide how to represent Corrigenda for 10646, nor which of these is preferred. (Giving a Unicode version is more accurate, as the case folding and mapping rules always come from a Unicode version [10646 just tells one to look at Unicode to get those], and the character classifications ought to be the same for equivalent versions, but we don't want to talk about non-ISO standards in an ISO standard.) 62.a/3

NOTES

8 {AI05-0266-1} The results returned by these functions may depend on which particular version of the 10646 standard is supported by the implementation (see 2.1). 63/3

9 {AI05-0286-1} The case insensitive equality comparison routines provided in A.4.10, “String Comparison” are also available for wide strings (see A.4.7). 64/3

Extensions to Ada 2005

{AI05-0185-1} {AI05-0266-1} The package Wide_Characters.Handling is new. 64.a/3

A.3.6 The Package Wide_Wide_Characters.Handling

{AI05-0185-1} The package Wide_Wide_Characters.Handling has the same contents as Wide_Characters.Handling except that each occurrence of Wide_Character is replaced by Wide_Wide_Character, and each occurrence of Wide_String is replaced by Wide_Wide_String. 1/3

Extensions to Ada 2005

{AI05-0185-1} The package Wide_Wide_Characters.Handling is new. 1.a/3

A.4 String Handling

{AI95-00285-01} {AI05-0299-1} This subclause presents the specifications of the package Strings and several child packages, which provide facilities for dealing with string data. Fixed-length, bounded-length, and unbounded-length strings are supported, for String, Wide_String, and Wide_Wide_String. The string-handling subprograms include searches for pattern strings and for characters in program- 1/3

specified sets, translation (via a character-to-character mapping), and transformation (replacing, inserting, overwriting, and deleting of substrings).

Extensions to Ada 83

1.a/3 {AI05-0299-1} This subclause is new to Ada 95.

Wording Changes from Ada 95

1.b/2 {AI95-00285-01} Included `Wide_Wide_String` in this description; the individual changes are documented as extensions as needed.

A.4.1 The Package Strings

1 The package Strings provides declarations common to the string handling packages.

Static Semantics

2 The library package Strings has the following declaration:

```

3  package Ada.Strings is
4    pragma Pure(Strings);
4/2  {AI95-00285-01}  Space      : constant Character      := ' ';
      Wide_Space : constant Wide_Character := ' ';
      Wide_Wide_Space : constant Wide_Wide_Character := ' ';
5    Length_Error, Pattern_Error, Index_Error, Translation_Error : exception;
6    type Alignment is (Left, Right, Center);
      type Truncation is (Left, Right, Error);
      type Membership is (Inside, Outside);
      type Direction is (Forward, Backward);
      type Trim_End is (Left, Right, Both);
end Ada.Strings;
```

Incompatibilities With Ada 95

6.a/3 {AI95-00285-01} {AI05-0005-1} Constant `Wide_Wide_Space` is added to `Ada.Strings`. If `Ada.Strings` is referenced in a `use_clause`, and an entity *E* with a `defining_identifier` of `Wide_Wide_Space` is defined in a package that is also referenced in a `use_clause`, the entity *E* may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur.

A.4.2 The Package Strings.Maps

1 The package Strings.Maps defines the types, operations, and other entities needed for character sets and character-to-character mappings.

Static Semantics

2 The library package Strings.Maps has the following declaration:

```

3/2  {AI95-00362-01} package Ada.Strings.Maps is
      pragma Pure(Maps);
4/2  {AI95-00161-01}  -- Representation for a set of character values:
      type Character_Set is private;
      pragma Preelaborable_Initialization(Character_Set);
5    Null_Set : constant Character_Set;
6    type Character_Range is
      record
          Low  : Character;
          High : Character;
      end record;
      -- Represents Character range Low..High
```

```

type Character_Ranges is array (Positive range <>) of Character_Range;           7
function To_Set      (Ranges : in Character_Ranges) return Character_Set;         8
function To_Set      (Span   : in Character_Range) return Character_Set;         9
function To_Ranges  (Set     : in Character_Set)   return Character_Ranges;      10
function "="        (Left, Right : in Character_Set) return Boolean;           11
function "not"      (Right : in Character_Set)      return Character_Set;       12
function "and"      (Left, Right : in Character_Set) return Character_Set;     12
function "or"       (Left, Right : in Character_Set) return Character_Set;     12
function "xor"      (Left, Right : in Character_Set) return Character_Set;     12
function "-"        (Left, Right : in Character_Set) return Character_Set;     12
function Is_In      (Element : in Character;
                     Set      : in Character_Set)
    return Boolean;
function Is_Subset  (Elements : in Character_Set;
                     Set      : in Character_Set)
    return Boolean;
function "<="      (Left  : in Character_Set;
                  Right : in Character_Set)
    return Boolean renames Is_Subset;
-- Alternative representation for a set of character values:
subtype Character_Sequence is String;
function To_Set      (Sequence : in Character_Sequence) return Character_Set;    17
function To_Set      (Singleton : in Character)         return Character_Set;    18
function To_Sequence (Set       : in Character_Set) return Character_Sequence;    19
{AI95-00161-01} -- Representation for a character to character mapping:
type Character_Mapping is private;
pragma Preelaborable_Initialization(Character_Mapping);
function Value (Map      : in Character_Mapping;
               Element : in Character)
    return Character;
Identity : constant Character_Mapping;
function To_Mapping (From, To : in Character_Sequence)
    return Character_Mapping;
function To_Domain (Map : in Character_Mapping)
    return Character_Sequence;
function To_Range (Map : in Character_Mapping)
    return Character_Sequence;
type Character_Mapping_Function is
    access function (From : in Character) return Character;
private
    ... -- not specified by the language
end Ada.Strings.Maps;

```

An object of type `Character_Set` represents a set of characters.

`Null_Set` represents the set containing no characters.

An object `Obj` of type `Character_Range` represents the set of characters in the range `Obj.Low .. Obj.High`.

An object `Obj` of type `Character_Ranges` represents the union of the sets corresponding to `Obj(I)` for `I` in `Obj'Range`.

```

function To_Set (Ranges : in Character_Ranges) return Character_Set;           31
    {AI05-0264-1} If Ranges'Length=0 then Null_Set is returned; otherwise, the returned value 32/3
    represents the set corresponding to Ranges.

```

33 **function** To_Set (Span : **in** Character_Range) **return** Character_Set;

34 The returned value represents the set containing each character in Span.

35 **function** To_Ranges (Set : **in** Character_Set) **return** Character_Ranges;

36/3 {AI05-0264-1} If Set = Null_Set, then an empty Character_Ranges array is returned; otherwise, the shortest array of contiguous ranges of Character values in Set, in increasing order of Low, is returned.

37 **function** "=" (Left, Right : **in** Character_Set) **return** Boolean;

38 The function "=" returns True if Left and Right represent identical sets, and False otherwise.

39 Each of the logical operators "**not**", "**and**", "**or**", and "**xor**" returns a Character_Set value that represents the set obtained by applying the corresponding operation to the set(s) represented by the parameter(s) of the operator. "-"(Left, Right) is equivalent to "and"(Left, "not"(Right)).

39.a **Reason:** The set minus operator is provided for efficiency.

40 **function** Is_In (Element : **in** Character;
Set : **in** Character_Set);
return Boolean;

41 Is_In returns True if Element is in Set, and False otherwise.

42 **function** Is_Subset (Elements : **in** Character_Set;
Set : **in** Character_Set)
return Boolean;

43 Is_Subset returns True if Elements is a subset of Set, and False otherwise.

44 **subtype** Character_Sequence **is** String;

45 The Character_Sequence subtype is used to portray a set of character values and also to identify the domain and range of a character mapping.

45.a **Reason:** Although a named subtype is redundant — the predefined type String could have been used for the parameter to To_Set and To_Mapping below — the use of a differently named subtype identifies the intended purpose of the parameter.

46 **function** To_Set (Sequence : **in** Character_Sequence) **return** Character_Set;

function To_Set (Singleton : **in** Character) **return** Character_Set;

47 Sequence portrays the set of character values that it explicitly contains (ignoring duplicates). Singleton portrays the set comprising a single Character. Each of the To_Set functions returns a Character_Set value that represents the set portrayed by Sequence or Singleton.

48 **function** To_Sequence (Set : **in** Character_Set) **return** Character_Sequence;

49 The function To_Sequence returns a Character_Sequence value containing each of the characters in the set represented by Set, in ascending order with no duplicates.

50 **type** Character_Mapping **is private**;

51 An object of type Character_Mapping represents a Character-to-Character mapping.

52 **function** Value (Map : **in** Character_Mapping;
Element : **in** Character)
return Character;

53 The function Value returns the Character value to which Element maps with respect to the mapping represented by Map.

A character *C* *matches* a pattern character *P* with respect to a given `Character_Mapping` value `Map` if `Value(Map, C) = P`. A string *S* *matches* a pattern string *P* with respect to a given `Character_Mapping` if their lengths are the same and if each character in *S* matches its corresponding character in the pattern string *P*. 54

Discussion: In an earlier version of the string handling packages, the definition of matching was symmetrical, namely *C* matches *P* if `Value(Map,C) = Value(Map,P)`. However, applying the mapping to the pattern was confusing according to some reviewers. Furthermore, if the symmetrical version is needed, it can be achieved by applying the mapping to the pattern (via translation) prior to passing it as a parameter. 54.a

String handling subprograms that deal with character mappings have parameters whose type is `Character_Mapping`. 55

`Identity` : **constant** `Character_Mapping`; 56

Identity maps each `Character` to itself. 57

function `To_Mapping` (`From, To` : **in** `Character_Sequence`)
return `Character_Mapping`; 58

`To_Mapping` produces a `Character_Mapping` such that each element of `From` maps to the corresponding element of `To`, and each other character maps to itself. If `From'Length /= To'Length`, or if some character is repeated in `From`, then `Translation_Error` is propagated. 59

function `To_Domain` (`Map` : **in** `Character_Mapping`) **return** `Character_Sequence`; 60

`To_Domain` returns the shortest `Character_Sequence` value `D` such that each character not in `D` maps to itself, and such that the characters in `D` are in ascending order. The lower bound of `D` is 1. 61

function `To_Range` (`Map` : **in** `Character_Mapping`) **return** `Character_Sequence`; 62

{8652/0048} {AI95-00151-01} `To_Range` returns the `Character_Sequence` value `R`, such that if `D = To_Domain(Map)`, then `R` has the same bounds as `D`, and `D(I)` maps to `R(I)` for each `I` in `D'Range`. 63/1

An object `F` of type `Character_Mapping_Function` maps a `Character` value `C` to the `Character` value `F.all(C)`, which is said to *match* `C` with respect to mapping function `F`. 64

NOTES

10 `Character_Mapping` and `Character_Mapping_Function` are used both for character equivalence mappings in the search subprograms (such as for case insensitivity) and as transformational mappings in the `Translate` subprograms. 65

11 `To_Domain(Identity)` and `To_Range(Identity)` each returns the null string. 66

Reason: Package `Strings.Maps` is not pure, since it declares an access-to-subprogram type. 66.a

Examples

`To_Mapping("ABCD", "ZZAB")` returns a `Character_Mapping` that maps 'A' and 'B' to 'Z', 'C' to 'A', 'D' to 'B', and each other `Character` to itself. 67

Extensions to Ada 95

{AI95-00161-01} **Amendment Correction:** Added `pragma Preelaborable_Initialization` to types `Character_Set` and `Character_Mapping`, so that they can be used to declare default-initialized objects in preelaborated units. 67.a/2

{AI95-00362-01} `Strings.Maps` is now Pure, so it can be used in pure units. 67.b/2

Wording Changes from Ada 95

{8652/0048} {AI95-00151-01} **Corrigendum:** Corrected the definition of the range of the result of `To_Range`, since the Ada 95 definition makes no sense. 67.c/2

A.4.3 Fixed-Length String Handling

1 The language-defined package `Strings.Fixed` provides string-handling subprograms for fixed-length strings; that is, for values of type `Standard.String`. Several of these subprograms are procedures that modify the contents of a `String` that is passed as an **out** or an **in out** parameter; each has additional parameters to control the effect when the logical length of the result differs from the parameter's length.

2 For each function that returns a `String`, the lower bound of the returned value is 1.

2.a/2 **Discussion:** *{AI95-00114-01}* Most operations that yield a `String` are provided both as a function and as a procedure. The functional form is possibly a more aesthetic style but may introduce overhead due to extra copying or dynamic memory usage in some implementations. Thus a procedural form, with an **in out** parameter so that all copying is done 'in place', is also supplied.

3 The basic model embodied in the package is that a fixed-length string comprises significant characters and possibly padding (with space characters) on either or both ends. When a shorter string is copied to a longer string, padding is inserted, and when a longer string is copied to a shorter one, padding is stripped. The `Move` procedure in `Strings.Fixed`, which takes a `String` as an **out** parameter, allows the programmer to control these effects. Similar control is provided by the string transformation procedures.

Static Semantics

4 The library package `Strings.Fixed` has the following declaration:

```

5  with Ada.Strings.Maps;
6  package Ada.Strings.Fixed is
7      pragma Preelaborate(Fixed);
8      -- "Copy" procedure for strings of possibly different lengths
9      procedure Move (Source : in String;
10                     Target : out String;
11                     Drop : in Truncation := Error;
12                     Justify : in Alignment := Left;
13                     Pad : in Character := Space);
14
15      -- Search subprograms
16      {AI95-00301-01} function Index (Source : in String;
17                                     Pattern : in String;
18                                     From : in Positive;
19                                     Going : in Direction := Forward;
20                                     Mapping : in Maps.Character_Mapping := Maps.Identity)
21          return Natural;
22      {AI95-00301-01} function Index (Source : in String;
23                                     Pattern : in String;
24                                     From : in Positive;
25                                     Going : in Direction := Forward;
26                                     Mapping : in Maps.Character_Mapping_Function)

                    Left    : in Maps.Character_Set;
                    Right   : in Maps.Character_Set;
                    Justify : in Alignment := Strings.Left;
                    Pad     : in Character := Space);

35     function Head (Source : in String;
                   Count   : in Natural;
                   Pad     : in Character := Space)
            return String;

36     procedure Head (Source : in out String;
                   Count   : in Natural;
                   Justify : in Alignment := Left;
                   Pad     : in Character := Space);

37     function Tail (Source : in String;
                   Count   : in Natural;
                   Pad     : in Character := Space)
            return String;

```

<code>procedure Tail (Source : in out String;</code>	38
<code> Count : in Natural;</code>	
<code> Justify : in Alignment := Left;</code>	
<code> Pad : in Character := Space);</code>	
<code>--String constructor functions</code>	39
<code>function "*" (Left : in Natural;</code>	40
<code> Right : in Character) return String;</code>	
<code>function "*" (Left : in Natural;</code>	41
<code> Right : in String) return String;</code>	
<code>end Ada.Strings.Fixed;</code>	42
The effects of the above subprograms are as follows.	43
<code>procedure Move (Source : in String;</code>	44
<code> Target : out String;</code>	
<code> Drop : in Truncation := Error;</code>	
<code> Justify : in Alignment := Left;</code>	
<code> Pad : in Character := Space);</code>	
<i>{AI05-0264-1}</i> The Move procedure copies characters from Source to Target. If Source has the same length as Target, then the effect is to assign Source to Target. If Source is shorter than Target, then:	45/3
• If Justify=Left, then Source is copied into the first Source'Length characters of Target.	46
• If Justify=Right, then Source is copied into the last Source'Length characters of Target.	47
• If Justify=Center, then Source is copied into the middle Source'Length characters of Target. In this case, if the difference in length between Target and Source is odd, then the extra Pad character is on the right.	48
• Pad is copied to each Target character not otherwise assigned.	49
If Source is longer than Target, then the effect is based on Drop.	50
• If Drop=Left, then the rightmost Target'Length characters of Source are copied into Target.	51
• If Drop=Right, then the leftmost Target'Length characters of Source are copied into Target.	52
• If Drop=Error, then the effect depends on the value of the Justify parameter and also on whether any characters in Source other than Pad would fail to be copied:	53
• If Justify=Left, and if each of the rightmost Source'Length-Target'Length characters in Source is Pad, then the leftmost Target'Length characters of Source are copied to Target.	54
• If Justify=Right, and if each of the leftmost Source'Length-Target'Length characters in Source is Pad, then the rightmost Target'Length characters of Source are copied to Target.	55
• Otherwise, Length_Error is propagated.	56
Ramification: The Move procedure will work even if Source and Target overlap.	56.a
Reason: The order of parameters (Source before Target) corresponds to the order in COBOL's MOVE verb.	56.b

- 56.1/2
- ```

function Index (Source : in String;
 Pattern : in String;
 From : in Positive;
 Going : in Direction := Forward;
 Mapping : in Maps.Character_Mapping := Maps.Identity)
return Natural;

function Index (Source : in String;
 Pattern : in String;
 From : in Positive;
 Going : in Direction := Forward;
 Mapping : in Maps.Character_Mapping_Function)
return Natural;

```
- 56.2/3 *{AI95-00301-01}* *{AI05-0056-1}* Each Index function searches, starting from From, for a slice of Source, with length Pattern'Length, that matches Pattern with respect to Mapping; the parameter Going indicates the direction of the lookup. If Source is the null string, Index returns 0; otherwise, if From is not in Source'Range, then Index\_Error is propagated. If Going = Forward, then Index returns the smallest index I which is greater than or equal to From such that the slice of Source starting at I matches Pattern. If Going = Backward, then Index returns the largest index I such that the slice of Source starting at I matches Pattern and has an upper bound less than or equal to From. If there is no such slice, then 0 is returned. If Pattern is the null string, then Pattern\_Error is propagated.
- 56.c/2 **Discussion:** There is no default parameter for From; the default value would need to depend on other parameters (the bounds of Source and the direction Going). It is better to use overloaded functions rather than a special value to represent the default.
- 56.d/2 There is no default value for the Mapping parameter that is a Character\_Mapping\_Function; if there were, a call would be ambiguous since there is also a default for the Mapping parameter that is a Character\_Mapping.
- 56.e/3 *{AI05-0056-1}* The language does not define when the Pattern\_Error check is made. (That's because many common searching implementations require a nonempty pattern) That means that the result for a call like Index ("", "") could be 0 or could raise Pattern\_Error. Similarly, in the call Index ("", "", From => 2), the language does not define whether Pattern\_Error or Index\_Error is raised.

| <p><b>Reason:</b> We say 'maximum number' because it is possible to slice a source string in different ways yielding different numbers of matches. For example if Source is "ABABABA" and Pattern is "ABA", then Count yields 2, although there is a partitioning of Source that yields just 1 match, for the middle slice. Saying 'maximum number' is equivalent to saying that the pattern match starts either at the low index or the high index position.</p>                                                                                                                                              | 64.a   |

- 94       Returns the string obtained by removing from Source all leading characters in Left and all trailing characters in Right.
- 95       **procedure** Trim (Source   : **in out** String;  
                   Left    : **in** Maps.Character\_Set;  
                   Right   : **in** Maps.Character\_Set;  
                   Justify : **in** Alignment := Strings.Left;  
                   Pad     : **in** Character := Space);
- 96       Equivalent to Move(Trim(Source, Left, Right), Source, Justify => Justify, Pad=>Pad).
- 97       **function** Head (Source : **in** String;  
                   Count : **in** Natural;  
                   Pad    : **in** Character := Space)  
           **return** String;
- 98/3       {AI05-0264-1} Returns a string of length Count. If Count <= Source'Length, the string comprises the first Count characters of Source. Otherwise, its contents are Source concatenated with Count-Source'Length Pad characters.
- 99       **procedure** Head (Source : **in out** String;  
                   Count : **in** Natural;  
                   Justify : **in** Alignment := Left;  
                   Pad     : **in** Character := Space);
- 100       Equivalent to Move(Head(Source, Count, Pad), Source, Drop=>Error, Justify=>Justify, Pad=>Pad).
- 101       **function** Tail (Source : **in** String;  
                   Count : **in** Natural;  
                   Pad    : **in** Character := Space)  
           **return** String;
- 102/3       {AI05-0264-1} Returns a string of length Count. If Count <= Source'Length, the string comprises the last Count characters of Source. Otherwise, its contents are Count-Source'Length Pad characters concatenated with Source.
- 103       **procedure** Tail (Source : **in out** String;  
                   Count : **in** Natural;  
                   Justify : **in** Alignment := Left;  
                   Pad     : **in** Character := Space);
- 104       Equivalent to Move(Tail(Source, Count, Pad), Source, Drop=>Error, Justify=>Justify, Pad=>Pad).
- 105       **function** "\*" (Left : **in** Natural;  
                   Right : **in** Character) **return** String;
- function** "\*" (Left : **in** Natural;  
                   Right : **in** String) **return** String;
- 106/1       {8652/0049} {AI95-00128-01} These functions replicate a character or string a specified number of times. The first function returns a string whose length is Left and each of whose elements is Right. The second function returns a string whose length is Left\*Right'Length and whose value is the null string if Left = 0 and otherwise is (Left-1)\*Right & Right with lower bound 1.
- NOTES
- 107/3       12 {AI05-0264-1} In the Index and Count functions taking Pattern and Mapping parameters, the actual String parameter passed to Pattern should comprise characters occurring as target characters of the mapping. Otherwise, the pattern will not match.

- 13 In the Insert subprograms, inserting at the end of a string is obtained by passing Source'Last+1 as the Before parameter. 108
- 14 If a null Character\_Mapping\_Function is passed to any of the string handling subprograms, Constraint\_Error is propagated. 109

*Incompatibilities With Ada 95*

- {AI95-00301-01} {AI05-0005-1} Overloaded versions of Index and Index\_Non\_Blank are added to Strings.Fixed. If Strings.Fixed is referenced in a use\_clause, and an entity *E* with a defining\_identifier of Index or Index\_Non\_Blank is defined in a package that is also referenced in a use\_clause, the entity *E* may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur. 109.a/3

*Wording Changes from Ada 95*

- {8652/0049} {AI95-00128-01} **Corrigendum:** Clarified that Find-Token may raise Constraint\_Error if Source'First is not in Positive (which is only possible for a null string). 109.b/2

- {8652/0049} {AI95-00128-01} **Corrigendum:** Clarified that Replace\_Slice, Delete, and "\*" always return a string with lower bound 1. 109.c/2

*Incompatibilities With Ada 2005*

- {AI05-0031-1} An overloaded version of Find-Token is added to Strings.Fixed. If Strings.Fixed is referenced in a use\_clause, and an entity *E* with a defining\_identifier of Find-Token is defined in a package that is also referenced in a use\_clause, the entity *E* may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur. 109.d/3

*Wording Changes from Ada 2005*

- {AI05-0056-1} **Correction:** Clarified that Index never raises Index\_Error if the source string is null. 109.e/3

## A.4.4 Bounded-Length String Handling

The language-defined package Strings.Bounded provides a generic package each of whose instances yields a private type Bounded\_String and a set of operations. An object of a particular Bounded\_String type represents a String whose low bound is 1 and whose length can vary conceptually between 0 and a maximum size established at the generic instantiation. The subprograms for fixed-length string handling are either overloaded directly for Bounded\_String, or are modified as needed to reflect the variability in length. Additionally, since the Bounded\_String type is private, appropriate constructor and selector operations are provided. 1

**Reason:** Strings.Bounded declares an inner generic package, versus itself being directly a generic child of Strings, in order to retain compatibility with a version of the string-handling packages that is generic with respect to the character and string types. 1.a

**Reason:** The bound of a bounded-length string is specified as a parameter to a generic, versus as the value for a discriminant, because of the inappropriateness of assignment and equality of discriminated types for the copying and comparison of bounded strings. 1.b

*Static Semantics*

The library package Strings.Bounded has the following declaration: 2

```
with Ada.Strings.Maps;
package Ada.Strings.Bounded is
 pragma Preelaborate(Bounded);
 generic
 Max : Positive; -- Maximum length of a Bounded_String
 package Generic_Bounded_Length is
 Max_Length : constant Positive := Max;
 type Bounded_String is private;
 Null_Bounded_String : constant Bounded_String;
 subtype Length_Range is Natural range 0 .. Max_Length;
 end package;
end package;
```

3  
4  
5  
6  
7  
8

```

82.a.1/2 *This paragraph was deleted. {8652/0097} {AI95-00115-01} {AI95-00344-01}*

Null\_Bounded\_String represents the null string. If an object of type Bounded\_String is not otherwise initialized, it will be initialized to the same value as Null\_Bounded\_String.

```

84 function Length (Source : in Bounded_String) return Length_Range;

```

85 The Length function returns the length of the string represented by Source.

```

86 function To_Bounded_String (Source : in String;
 Drop : in Truncation := Error)
 return Bounded_String;

```

87/3 *{AI05-0264-1}* If Source'Length <= Max\_Length, then this function returns a Bounded\_String that represents Source. Otherwise, the effect depends on the value of Drop:

- 88 • If Drop=Left, then the result is a Bounded\_String that represents the string comprising the rightmost Max\_Length characters of Source.
- 89 • If Drop=Right, then the result is a Bounded\_String that represents the string comprising the leftmost Max\_Length characters of Source.
- 90 • If Drop=Error, then Strings.Length\_Error is propagated.

- 102 Each of the functions "=", "<", ">", "<=", and ">=" returns the same result as the corresponding String operation applied to the String values given or represented by the two parameters.
- 103 Each of the search subprograms (Index, Index\_Non\_Blank, Count, Find-Token) has the same effect as the corresponding subprogram in Strings.Fixed applied to the string represented by the Bounded\_String parameter.
- 104 Each of the Translate subprograms, when applied to a Bounded\_String, has an analogous effect to the corresponding subprogram in Strings.Fixed. For the Translate function, the translation is applied to the string represented by the Bounded\_String parameter, and the result is converted (via To\_Bounded\_String) to a Bounded\_String. For the Translate procedure, the string represented by the Bounded\_String parameter after the translation is given by the Translate function for fixed-length strings applied to the string represented by the original value of the parameter.
- 105/1 {8652/0049} {AI95-00128-01} Each of the transformation subprograms (Replace\_Slice, Insert, Overwrite, Delete), selector subprograms (Trim, Head, Tail), and constructor functions ("\*") has an effect based on its corresponding subprogram in Strings.Fixed, and Replicate is based on Fixed.\*. In the case of a function, the corresponding fixed-length string subprogram is applied to the string represented by the Bounded\_String parameter. To\_Bounded\_String is applied the result string, with Drop (or Error in the case of Generic\_Bounded\_Length.\*) determining the effect when the string length exceeds Max\_Length. In the case of a procedure, the corresponding function in Strings.Bounded.Generic\_Bounded\_Length is applied, with the result assigned into the Source parameter.
- 105.a/2 **Ramification:** {AI95-00114-01} The "/=" operations between Bounded\_String and String, and between String and Bounded\_String, are automatically defined based on the corresponding "=" operations.

*Implementation Advice*

- 106 Bounded string objects should not be implemented by implicit pointers and dynamic allocation.
- 106.a.1/2 **Implementation Advice:** Bounded string objects should not be implemented by implicit pointers and dynamic allocation.
- 106.a **Implementation Note:** The following is a possible implementation of the private part of the package:
- 106.b 

```
type Bounded_String_Internals (Length : Length_Range := 0) is
 record
 Data : String(1..Length);
 end record;
```
- 106.c 

```
type Bounded_String is
 record
 Data : Bounded_String_Internals; -- Unconstrained
 end record;
```
- 106.d 

```
Null_Bounded_String : constant Bounded_String :=
 (Data => (Length => 0,
 Data => (1..0 => ' ')));
```

*Inconsistencies With Ada 95*

- 106.e/2 {AI95-00238-01} **Amendment Correction:** The bounds of the string returned from Slice are now defined. This is technically an inconsistency; if a program depended on some other lower bound for the string returned from Slice, it could fail when compiled with Ada 2005. Such code is not portable even between Ada 95 implementations, so it should be very rare.

*Incompatibilities With Ada 95*

- 106.f/3 {AI95-00301-01} {AI05-0005-1} Procedure Set\_Bounded\_String, two Bounded\_Slice subprograms, and overloaded versions of Index and Index\_Non\_Blank are added to Strings.Bounded.Generic\_Bounded\_Length. If an instance of Generic\_Bounded\_Length is referenced in a use\_clause, and an entity E with the defining\_identifier as a new entity in Generic\_Bounded\_Length is defined in a package that is also referenced in a use\_clause, the entity E may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur.

*Wording Changes from Ada 95*

- {8652/0049} {AI95-00128-01} **Corrigendum:** Corrected the conditions for which Slice raises Index\_Error. 106.g/2
- {8652/0049} {AI95-00128-01} **Corrigendum:** Clarified the meaning of transformation, selector, and constructor subprograms by describing the effects of procedures and functions separately. 106.h/2

*Incompatibilities With Ada 2005*

- {AI05-0031-1} An overloaded version of Find-Token is added to Strings.Bounded.Generic\_Bounded\_Length. If an instance of Generic\_Bounded\_Length is referenced in a use\_clause, and an entity *E* with a defining\_identifier of Find-Token is defined in a package that is also referenced in a use\_clause, the entity *E* may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur. 106.i/3

## A.4.5 Unbounded-Length String Handling

The language-defined package Strings.Unbounded provides a private type Unbounded\_String and a set of operations. An object of type Unbounded\_String represents a String whose low bound is 1 and whose length can vary conceptually between 0 and Natural'Last. The subprograms for fixed-length string handling are either overloaded directly for Unbounded\_String, or are modified as needed to reflect the flexibility in length. Since the Unbounded\_String type is private, relevant constructor and selector operations are provided. 1

**Reason:** The transformation operations for fixed- and bounded-length strings that are not necessarily length preserving are supplied for Unbounded\_String as procedures as well as functions. This allows an implementation to do an initial allocation for an unbounded string and to avoid further allocations as long as the length does not exceed the allocated length. 1.a

*Static Semantics*

The library package Strings.Unbounded has the following declaration: 2

```

with Ada.Strings.Maps;
package Ada.Strings.Unbounded is

| <code>{AI95-00360-01}</code> The type <code>Unbounded_String</code> needs finalization (see 7.6).                                                                                                                                                                                                                                                       | 72.1/2   |
| <code>Null_Unbounded_String</code> represents the null <code>String</code> . If an object of type <code>Unbounded_String</code> is not otherwise initialized, it will be initialized to the same value as <code>Null_Unbounded_String</code> .                                                                                                          | 73       |
| The function <code>Length</code> returns the length of the <code>String</code> represented by <code>Source</code> .                                                                                                                                                                                                                                     | 74       |
| The type <code>String_Access</code> provides a (nonprivate) access type for explicit processing of unbounded-length strings. The procedure <code>Free</code> performs an unchecked deallocation of an object of type <code>String_Access</code> .                                                                                                       | 75       |
| The function <code>To_Unbounded_String(Source : in String)</code> returns an <code>Unbounded_String</code> that represents <code>Source</code> . The function <code>To_Unbounded_String(Length : in Natural)</code> returns an <code>Unbounded_String</code> that represents an uninitialized <code>String</code> whose length is <code>Length</code> . | 76       |
| The function <code>To_String</code> returns the <code>String</code> with lower bound 1 represented by <code>Source</code> . <code>To_String</code> and <code>To_Unbounded_String</code> are related as follows:                                                                                                                                         | 77       |
| <ul style="list-style-type: none"> <li>• If <code>S</code> is a <code>String</code>, then <code>To_String(To_Unbounded_String(S)) = S</code>.</li> <li>• If <code>U</code> is an <code>Unbounded_String</code>, then <code>To_Unbounded_String(To_String(U)) = U</code>.</li> </ul>                                                                     | 78<br>79 |
| <code>{AI95-00301-01}</code> The procedure <code>Set_Unbounded_String</code> sets <code>Target</code> to an <code>Unbounded_String</code> that represents <code>Source</code> .                                                                                                                                                                         | 79.1/2   |
| For each of the <code>Append</code> procedures, the resulting string represented by the <code>Source</code> parameter is given by the concatenation of the original value of <code>Source</code> and the value of <code>New_Item</code> .                                                                                                               | 80       |
| Each of the <code>"&amp;"</code> functions returns an <code>Unbounded_String</code> obtained by concatenating the string or character given or represented by one of the parameters, with the string or character given or represented by the other parameter, and applying <code>To_Unbounded_String</code> to the concatenation result string.        | 81       |

- 82 The Element, Replace\_Element, and Slice subprograms have the same effect as the corresponding bounded-length string subprograms.
- 82.1/3 {AI95-00301-01} {AI05-0262-1} The function Unbounded\_Slice returns the slice at positions Low through High in the string represented by Source as an Unbounded\_String. The procedure Unbounded\_Slice sets Target to the Unbounded\_String representing the slice at positions Low through High in the string represented by Source. Both subprograms propagate Index\_Error if Low > Length(Source)+1 or High > Length(Source).
- 83 Each of the functions "=", "<", ">", "<=", and ">=" returns the same result as the corresponding String operation applied to the String values given or represented by Left and Right.
- 84 Each of the search subprograms (Index, Index\_Non\_Blank, Count, Find-Token) has the same effect as the corresponding subprogram in Strings.Fixed applied to the string represented by the Unbounded\_String parameter.
- 85 The Translate function has an analogous effect to the corresponding subprogram in Strings.Fixed. The translation is applied to the string represented by the Unbounded\_String parameter, and the result is converted (via To\_Unbounded\_String) to an Unbounded\_String.
- 86 Each of the transformation functions (Replace\_Slice, Insert, Overwrite, Delete), selector functions (Trim, Head, Tail), and constructor functions ("\*") is likewise analogous to its corresponding subprogram in Strings.Fixed. For each of the subprograms, the corresponding fixed-length string subprogram is applied to the string represented by the Unbounded\_String parameter, and To\_Unbounded\_String is applied the result string.
- 87 For each of the procedures Translate, Replace\_Slice, Insert, Overwrite, Delete, Trim, Head, and Tail, the resulting string represented by the Source parameter is given by the corresponding function for fixed-length strings applied to the string represented by Source's original value.

*Implementation Requirements*

- 88 No storage associated with an Unbounded\_String object shall be lost upon assignment or scope exit.
- 88.a/2 **Implementation Note:** {AI95-00301-01} A sample implementation of the private part of the package and several of the subprograms appears in the Ada 95 Rationale.

*Incompatibilities With Ada 95*

- 88.b/2 {AI95-00360-01} **Amendment Correction:** Type Unbounded\_String is defined to need finalization. If the restriction No\_Nested\_Finalization (see D.7) applies to the partition, and Unbounded\_String does not have a controlled part, it will not be allowed in local objects in Ada 2005 whereas it would be allowed in original Ada 95. Such code is not portable, as most Ada compilers have a controlled part in Unbounded\_String, and thus would be illegal.
- 88.c/3 {AI95-00301-01} {AI05-0005-1} Procedure Set\_Unbounded\_String, two Unbounded\_Slice subprograms, and overloaded versions of Index and Index\_Non\_Blank are added to Strings.Unbounded. If Strings.Unbounded is referenced in a use\_clause, and an entity  $\bar{E}$  with the same defining\_identifier as a new entity in Strings.Unbounded is defined in a package that is also referenced in a use\_clause, the entity  $E$  may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur.

*Extensions to Ada 95*

- 88.d/2 {AI95-00161-01} **Amendment Correction:** Added a pragma Preelaborable\_Initialization to type Unbounded\_String, so that it can be used to declare default-initialized objects in preelaborated units.

*Incompatibilities With Ada 2005*

- 88.e/3 {AI05-0031-1} An overloaded version of Find-Token is added to Strings.Unbounded. If Strings.Unbounded is referenced in a use\_clause, and an entity  $E$  with a defining\_identifier of Find-Token is defined in a package that is also referenced in a use\_clause, the entity  $E$  may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur.

## A.4.6 String-Handling Sets and Mappings

The language-defined package `Strings.Maps.Constants` declares `Character_Set` and `Character_Mapping` constants corresponding to classification and conversion functions in package `Characters.Handling`. 1

**Discussion:** The `Constants` package is a child of `Strings.Maps` since it needs visibility of the private part of `Strings.Maps` in order to initialize the constants in a prelaborable way (i.e. via aggregates versus function calls). 1.a

### Static Semantics

The library package `Strings.Maps.Constants` has the following declaration: 2

```
{AI95-00362-01} package Ada.Strings.Maps.Constants is 3/2
 pragma Pure(Constants);
 Control_Set : constant Character_Set; 4
 Graphic_Set : constant Character_Set;
 Letter_Set : constant Character_Set;
 Lower_Set : constant Character_Set;
 Upper_Set : constant Character_Set;
 Basic_Set : constant Character_Set;
 Decimal_Digit_Set : constant Character_Set;
 Hexadecimal_Digit_Set : constant Character_Set;
 Alphanumeric_Set : constant Character_Set;
 Special_Set : constant Character_Set;
 ISO_646_Set : constant Character_Set;
 Lower_Case_Map : constant Character_Mapping; 5
 -- Maps to lower case for letters, else identity
 Upper_Case_Map : constant Character_Mapping;
 -- Maps to upper case for letters, else identity
 Basic_Map : constant Character_Mapping;
 -- Maps to basic letter for letters, else identity

 private 6
 ... -- not specified by the language
end Ada.Strings.Maps.Constants;
```

Each of these constants represents a correspondingly named set of characters or character mapping in `Characters.Handling` (see A.3.2). 7

### NOTES

15 {AI05-0114-1} There are certain characters which are defined to be lower case letters by ISO 10646 and are therefore allowed in identifiers, but are not considered lower case letters by `Ada.Strings.Maps.Constants`. 8/3

**Reason:** This is to maintain runtime compatibility with the Ada 95 definitions of these constants; existing correct programs could break if the definitions were changed in a way the programs did not anticipate. 8.a/3

### Extensions to Ada 95

{AI95-00362-01} `Strings.Maps.Constants` is now `Pure`, so it can be used in pure units. 8.b/2

### Wording Changes from Ada 2005

{AI05-0114-1} **Correction:** Added a note to clarify that these constants don't have any relationship to the characters allowed in identifiers. 8.c/3

## A.4.7 Wide\_String Handling

{AI95-00302-03} {AI05-0286-1} Facilities for handling strings of `Wide_Character` elements are found in the packages `Strings.Wide_Maps`, `Strings.Wide_Fixed`, `Strings.Wide_Bounded`, `Strings.Wide_Unbounded`, and `Strings.Wide_Maps.Wide_Constants`, and in the library functions `Strings.Wide_Hash`, `Strings.Wide_Fixed.Wide_Hash`, `Strings.Wide_Bounded.Wide_Hash`, `Strings.Wide_Unbounded.Wide_Hash`, `Strings.Wide_Hash_Case_Insensitive`, `Strings.Wide_Fixed.Wide_Hash_Case_Insensitive`, `Strings.Wide_Bounded.Wide_Hash_Case_Insensitive`, `Strings.Wide_Unbounded.Wide_Hash_Case_` 1/3

Insensitive, Strings.Wide\_Equal\_Case\_Insensitive, Strings.Wide\_Fixed.Wide\_Equal\_Case\_Insensitive, Strings.Wide\_Bounded.Wide\_Equal\_Case\_Insensitive, and Strings.Wide\_Unbounded.Wide\_Equal\_Case\_Insensitive. They provide the same string-handling operations as the corresponding packages and functions for strings of Character elements.

*Static Semantics*

2 The package Strings.Wide\_Maps has the following declaration.

```

3 package Ada.Strings.Wide_Maps is
4 pragma Preelaborate(Wide_Maps);
4/2 {AI95-00161-01} -- Representation for a set of Wide_Character values:
 type Wide_Character_Set is private;
 pragma Preelaborable_Initialization(Wide_Character_Set);
5 Null_Set : constant Wide_Character_Set;
6 type Wide_Character_Range is
 record
 Low : Wide_Character;
 High : Wide_Character;
 end record;
 -- Represents Wide_Character range Low..High
7 type Wide_Character_Ranges is array (Positive range <>)
 of Wide_Character_Range;
8 function To_Set (Ranges : in Wide_Character_Ranges)
 return Wide_Character_Set;
9 function To_Set (Span : in Wide_Character_Range)
 return Wide_Character_Set;
10 function To_Ranges (Set : in Wide_Character_Set)
 return Wide_Character_Ranges;
11 function "=" (Left, Right : in Wide_Character_Set) return Boolean;
12 function "not" (Right : in Wide_Character_Set)
 return Wide_Character_Set;
 function "and" (Left, Right : in Wide_Character_Set)
 return Wide_Character_Set;
 function "or" (Left, Right : in Wide_Character_Set)
 return Wide_Character_Set;
 function "xor" (Left, Right : in Wide_Character_Set)
 return Wide_Character_Set;
 function "-" (Left, Right : in Wide_Character_Set)
 return Wide_Character_Set;
13 function Is_In (Element : in Wide_Character;
 Set : in Wide_Character_Set)
 return Boolean;
14 function Is_Subset (Elements : in Wide_Character_Set;
 Set : in Wide_Character_Set)
 return Boolean;
15 function "<=" (Left : in Wide_Character_Set;
 Right : in Wide_Character_Set)
 return Boolean renames Is_Subset;
16 -- Alternative representation for a set of Wide_Character values:
 subtype Wide_Character_Sequence is Wide_String;
17 function To_Set (Sequence : in Wide_Character_Sequence)
 return Wide_Character_Set;
18 function To_Set (Singleton : in Wide_Character)
 return Wide_Character_Set;
19 function To_Sequence (Set : in Wide_Character_Set)
 return Wide_Character_Sequence;

```

```

{AI95-00161-01} -- Representation for a Wide_Character to Wide_Character mapping: 20/2
 type Wide_Character_Mapping is private;
 pragma Preelaborable_Initialization(Wide_Character_Mapping);
 function Value (Map : in Wide_Character_Mapping;
 Element : in Wide_Character) 21
 return Wide_Character;
 Identity : constant Wide_Character_Mapping; 22
 function To_Mapping (From, To : in Wide_Character_Sequence) 23
 return Wide_Character_Mapping;
 function To_Domain (Map : in Wide_Character_Mapping) 24
 return Wide_Character_Sequence;
 function To_Range (Map : in Wide_Character_Mapping) 25
 return Wide_Character_Sequence;
 type Wide_Character_Mapping_Function is 26
 access function (From : in Wide_Character) return Wide_Character;
 private 27
 ... -- not specified by the language
 end Ada.Strings.Wide_Maps;

```

The context clause for each of the packages `Strings.Wide_Fixed`, `Strings.Wide_Bounded`, and `Strings.Wide_Unbounded` identifies `Strings.Wide_Maps` instead of `Strings.Maps`. 28

{AI05-0223-1} Types `Wide_Character_Set` and `Wide_Character_Mapping` need finalization. 28.1/3

{AI95-00302-03} {AI05-0286-1} For each of the packages `Strings.Fixed`, `Strings.Bounded`, `Strings.Unbounded`, and `Strings.Maps.Constants`, and for library functions `Strings.Hash`, `Strings.Fixed.Hash`, `Strings.Bounded.Hash`, `Strings.Unbounded.Hash`, `Strings.Hash_Case_Insensitive`, `Strings.Fixed.Hash_Case_Insensitive`, `Strings.Bounded.Hash_Case_Insensitive`, `Strings.Unbounded.Hash_Case_Insensitive`, `Strings.Equal_Case_Insensitive`, `Strings.Fixed.Equal_Case_Insensitive`, `Strings.Bounded.Equal_Case_Insensitive`, and `Strings.Unbounded.Equal_Case_Insensitive`, the corresponding wide string package or function has the same contents except that 29/3

- `Wide_Space` replaces `Space` 30
- `Wide_Character` replaces `Character` 31
- `Wide_String` replaces `String` 32
- `Wide_Character_Set` replaces `Character_Set` 33
- `Wide_Character_Mapping` replaces `Character_Mapping` 34
- `Wide_Character_Mapping_Function` replaces `Character_Mapping_Function` 35
- `Wide_Maps` replaces `Maps` 36
- `Bounded_Wide_String` replaces `Bounded_String` 37
- `Null_Bounded_Wide_String` replaces `Null_Bounded_String` 38
- `To_Bounded_Wide_String` replaces `To_Bounded_String` 39
- `To_Wide_String` replaces `To_String` 40
- {AI95-00301-01} `Set_Bounded_Wide_String` replaces `Set_Bounded_String` 40.1/2
- `Unbounded_Wide_String` replaces `Unbounded_String` 41
- `Null_Unbounded_Wide_String` replaces `Null_Unbounded_String` 42
- `Wide_String_Access` replaces `String_Access` 43
- `To_Unbounded_Wide_String` replaces `To_Unbounded_String` 44

- 44.1/2 • *{AI95-00301-01}* Set\_Unbounded\_Wide\_String replaces Set\_Unbounded\_String

45 The following additional declaration is present in Strings.Wide\_Maps.Wide\_Constants:

```
46/2 {AI95-00285-01} {AI95-00395-01} Character_Set : constant
Wide_Maps.Wide_Character_Set;
--Contains each Wide_Character value WC such that
--Characters.Conversions.Is_Character(WC) is True
```

- 46.1/2 *{AI95-00395-01}* Each Wide\_Character\_Set constant in the package Strings.Wide\_Maps.Wide\_Constants contains no values outside the Character portion of Wide\_Character. Similarly, each Wide\_Character\_Mapping constant in this package is the identity mapping when applied to any element outside the Character portion of Wide\_Character.

- 46.2/2 *{AI95-00362-01}* Pragma Pure is replaced by pragma Preelaborate in Strings.Wide\_Maps.Wide\_Constants.

#### NOTES

- 47 16 If a null Wide\_Character\_Mapping\_Function is passed to any of the Wide\_String handling subprograms, Constraint\_Error is propagated.

#### *Incompatibilities With Ada 95*

- 48.a/2 *{AI95-00301-01}* Various new operations are added to Strings.Wide\_Fixed, Strings.Wide\_Bounded, and Strings.Wide\_Unbounded. If one of these packages is referenced in a use\_clause, and an entity *E* with the same defining\_identifier as a new entity is defined in a package that is also referenced in a use\_clause, the entity *E* may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur.

#### *Extensions to Ada 95*

- 48.b/2 *{AI95-00161-01}* **Amendment Correction:** Added pragma Preelaborable\_Initialization to types Wide\_Character\_Set and Wide\_Character\_Mapping, so that they can be used to declare default-initialized objects in preelaborated units.

#### *Wording Changes from Ada 95*

- 48.c/2 *{AI95-00285-01}* Corrected the description of Character\_Set.  
 48.d/2 *{AI95-00302-03}* Added wide versions of Strings.Hash and Strings.Unbounded.Hash.  
 48.e/2 *{AI95-00362-01}* Added wording so that Strings.Wide\_Maps.Wide\_Constants does not change to Pure.  
 48.f/2 *{AI95-00395-01}* The second Note is now normative text, since there is no way to derive it from the other rules. It's a little weird given the use of Unicode character classifications in Ada 2005; but changing it would be inconsistent with Ada 95 and a one-to-one mapping isn't necessarily correct anyway.

#### *Extensions to Ada 2005*

- 48.g/3 *{AI05-0286-1}* The case insensitive library functions (Strings.Wide\_Equal\_Case\_Insensitive, Strings.Wide\_Fixed.Wide\_Equal\_Case\_Insensitive, Strings.Wide\_Bounded.Wide\_Equal\_Case\_Insensitive, Strings.Wide\_Unbounded.Wide\_Equal\_Case\_Insensitive, Strings.Wide\_Hash\_Case\_Insensitive, Strings.Wide\_Fixed.Wide\_Hash\_Case\_Insensitive, Strings.Wide\_Bounded.Wide\_Hash\_Case\_Insensitive, and Strings.Wide\_Unbounded.Wide\_Hash\_Case\_Insensitive) are new.

#### *Wording Changes from Ada 2005*

- 48.h/3 *{AI05-0223-1}* **Correction:** Identified Wide\_Character\_Set and Wide\_Character\_Mapping as needing finalization. It is likely that they are implemented with a controlled type, so this change is unlikely to make any difference in practice.

## A.4.8 Wide\_Wide\_String Handling

- 1/3 *{AI95-00285-01}* *{AI95-00395-01}* *{AI05-0286-1}* Facilities for handling strings of Wide\_Wide\_Character elements are found in the packages Strings.Wide\_Wide\_Maps, Strings.Wide\_Wide\_Fixed, Strings.Wide\_Wide\_Bounded, Strings.Wide\_Wide\_Unbounded, and Strings.Wide\_Wide\_Maps.Wide\_Wide\_Constants, and in the library functions Strings.Wide\_Wide\_Hash, Strings.Wide\_Wide\_Fixed.Wide\_Wide\_Hash, Strings.Wide\_Wide\_Bounded.Wide\_Wide\_Hash, Strings.Wide\_Wide\_Unbounded.Wide\_Wide\_Hash, Strings.Wide\_Wide\_Hash\_Case\_Insensitive, Strings.Wide\_Wide\_Hash\_Case\_Insensitive, Strings.Wide\_Wide\_Hash\_Case\_Insensitive, and Strings.Wide\_Wide\_Hash\_Case\_Insensitive.

Wide\_Wide\_Fixed.Wide\_Wide\_Hash\_Case\_Insensitive, Strings.Wide\_Wide\_Bounded.Wide\_Wide\_Hash\_Case\_Insensitive, Strings.Wide\_Wide\_Unbounded.Wide\_Wide\_Hash\_Case\_Insensitive, Strings.Wide\_Wide\_Equal\_Case\_Insensitive, Strings.Wide\_Wide\_Fixed.Wide\_Wide\_Equal\_Case\_Insensitive, Strings.Wide\_Wide\_Bounded.Wide\_Wide\_Equal\_Case\_Insensitive, and Strings.Wide\_Wide\_Unbounded.Wide\_Wide\_Equal\_Case\_Insensitive. They provide the same string-handling operations as the corresponding packages and functions for strings of Character elements.

*Static Semantics*

```
{AI95-00285-01} The library package Strings.Wide_Wide_Maps has the following declaration. 2/2
package Ada.Strings.Wide_Wide_Maps is 3/2
 pragma Preelaborate(Wide_Wide_Maps);
 -- Representation for a set of Wide_Wide_Character values: 4/2
 type Wide_Wide_Character_Set is private;
 pragma Preelaborable_Initialization(Wide_Wide_Character_Set);
 Null_Set : constant Wide_Wide_Character_Set; 5/2
 type Wide_Wide_Character_Range is 6/2
 record
 Low : Wide_Wide_Character;
 High : Wide_Wide_Character;
 end record;
 -- Represents Wide_Wide_Character range Low..High
 type Wide_Wide_Character_Ranges is array (Positive range <>) 7/2
 of Wide_Wide_Character_Range;

 return Wide_Wide_Character;
22/2 Identity : constant Wide_Wide_Character_Mapping;
23/2 function To_Mapping (From, To : in Wide_Wide_Character_Sequence)
 return Wide_Wide_Character_Mapping;
24/2 function To_Domain (Map : in Wide_Wide_Character_Mapping)
 return Wide_Wide_Character_Sequence;
25/2 function To_Range (Map : in Wide_Wide_Character_Mapping)
 return Wide_Wide_Character_Sequence;
26/2 type Wide_Wide_Character_Mapping_Function is
 access function (From : in Wide_Wide_Character)
 return Wide_Wide_Character;
27/2 private
 ... -- not specified by the language
 end Ada.Strings.Wide_Wide_Maps;
28/2 {AI95-00285-01} The context clause for each of the packages Strings.Wide_Wide_Fixed,
Strings.Wide_Wide_Bounded, and Strings.Wide_Wide_Unbounded identifies Strings.Wide_Wide_Maps
instead of Strings.Maps.
28.1/3 {AI05-0223-1} Types Wide_Wide_Character_Set and Wide_Wide_Character_Mapping need finalization.
29/3 {AI95-00285-01} {AI05-0286-1} For each of the packages Strings.Fixed, Strings.Bounded, Strings.-
Unbounded, and Strings.Maps.Constants, and for library functions Strings.Hash, Strings.Fixed.Hash,
Strings.Bounded.Hash, Strings.Unbounded.Hash, Strings.Hash_Case_Insensitive, Strings.Fixed.Hash_-
Case_Insensitive, Strings.Bounded.Hash_Case_Insensitive, Strings.Unbounded.Hash_Case_Insensitive,
Strings.Equal_Case_Insensitive, Strings.Fixed.Equal_Case_Insensitive, Strings.Bounded.Equal_Case_-
Insensitive, and Strings.Unbounded.Equal_Case_Insensitive, the corresponding wide wide string package
or function has the same contents except that
30/2 • Wide_Wide_Space replaces Space
31/2 • Wide_Wide_Character replaces Character
32/2 • Wide_Wide_String replaces String
33/2 • Wide_Wide_Character_Set replaces Character_Set
34/2 • Wide_Wide_Character_Mapping replaces Character_Mapping
35/2 • Wide_Wide_Character_Mapping_Function replaces Character_Mapping_Function
36/2 • Wide_Wide_Maps replaces Maps
37/2 • Bounded_Wide_Wide_String replaces Bounded_String
38/2 • Null_Bounded_Wide_Wide_String replaces Null_Bounded_String
39/2 • To_Bounded_Wide_Wide_String replaces To_Bounded_String
40/2 • To_Wide_Wide_String replaces To_String
41/2 • {AI95-00301-01} Set_Bounded_Wide_Wide_String replaces Set_Bounded_String
42/2 • Unbounded_Wide_Wide_String replaces Unbounded_String

```

- Null\_Unbounded\_Wide\_Wide\_String replaces Null\_Unbounded\_String 43/2
  - Wide\_Wide\_String\_Access replaces String\_Access 44/2
  - To\_Unbounded\_Wide\_Wide\_String replaces To\_Unbounded\_String 45/2
  - {AI95-00301-01} Set\_Unbounded\_Wide\_Wide\_String replaces Set\_Unbounded\_String 46/2
- {AI95-00285-01} {AI95-00395-01} The following additional declarations are present in Strings.Wide\_Wide\_Maps.Wide\_Wide\_Constants: 47/2
- ```
Character_Set : constant Wide_Wide_Maps.Wide_Wide_Character_Set;
-- Contains each Wide_Wide_Character value WWC such that
-- Characters.Conversions.Is_Character(WWC) is True
Wide_Character_Set : constant Wide_Wide_Maps.Wide_Wide_Character_Set;
-- Contains each Wide_Wide_Character value WWC such that
-- Characters.Conversions.Is_Wide_Character(WWC) is True
```
- {AI95-00395-01} Each Wide_Wide_Character_Set constant in the package Strings.Wide_Wide_Maps.Wide_Wide_Constants contains no values outside the Character portion of Wide_Wide_Character. Similarly, each Wide_Wide_Character_Mapping constant in this package is the identity mapping when applied to any element outside the Character portion of Wide_Wide_Character. 49/2
- {AI95-00395-01} Pragma Pure is replaced by pragma Preelaborate in Strings.Wide_Wide_Maps.Wide_Wide_Constants. 50/2
- NOTES
- 17 {AI95-00285-01} If a null Wide_Wide_Character_Mapping_Function is passed to any of the Wide_Wide_String handling subprograms, Constraint_Error is propagated. 51/2

Extensions to Ada 95

- {AI95-00285-01} {AI95-00395-01} The double-wide string-handling packages (Strings.Wide_Wide_Maps, Strings.Wide_Wide_Fixed, Strings.Wide_Wide_Bounded, Strings.Wide_Wide_Unbounded, and Strings.Wide_Wide_Maps.Wide_Wide_Constants), and functions Strings.Wide_Wide_Hash and Strings.Wide_Wide_Unbounded.Wide_Wide_Hash are new. 51.a/2

Extensions to Ada 2005

- {AI05-0286-1} The case insensitive library functions (Strings.Wide_Wide_Equal_Case_Insensitive, Strings.Wide_Wide_Fixed.Wide_Wide_Equal_Case_Insensitive, Strings.Wide_Wide_Bounded.Wide_Wide_Equal_Case_Insensitive, Strings.Wide_Wide_Unbounded.Wide_Wide_Equal_Case_Insensitive, Strings.Wide_Wide_Hash_Case_Insensitive, Strings.Wide_Wide_Fixed.Wide_Wide_Hash_Case_Insensitive, Strings.Wide_Wide_Bounded.Wide_Wide_Hash_Case_Insensitive, and Strings.Wide_Wide_Unbounded.Wide_Wide_Hash_Case_Insensitive) are new. 51.b/3

Wording Changes from Ada 2005

- {AI05-0223-1} **Correction:** Identified Wide_Wide_Character_Set and Wide_Wide_Character_Mapping as needing finalization. It is likely that they are implemented with a controlled type, so this change is unlikely to make any difference in practice. 51.c/3

A.4.9 String Hashing

Static Semantics

- {AI95-00302-03} The library function Strings.Hash has the following declaration: 1/2
- ```
{AI05-0298-1} with Ada.Containers;
function Ada.Strings.Hash (Key : String) return Containers.Hash_Type;
pragma Pure (Ada.Strings.Hash);
```
- Returns an implementation-defined value which is a function of the value of Key. If *A* and *B* are strings such that *A* equals *B*, Hash(*A*) equals Hash(*B*). 3/2
- Implementation defined:** The values returned by Strings.Hash. 3.a/2

- 4/2 {AI95-00302-03} The library function Strings.Fixed.Hash has the following declaration:
- 5/3 {AI05-0298-1} with Ada.Containers, Ada.Strings.Hash;  
**function** Ada.Strings.Fixed.Hash (Key : String) **return** Containers.Hash\_Type  
**renames** Ada.Strings.Hash;
- 6/2 {AI95-00302-03} The generic library function Strings.Bounded.Hash has the following declaration:
- 7/3 {AI05-0298-1} with Ada.Containers;  
**generic**  
**with package** Bounded **is**  
**new** Ada.Strings.Bounded.Generic\_Bounded\_Length (<>);  
**function** Ada.Strings.Bounded.Hash (Key : Bounded.Bounded\_String)  
**return** Containers.Hash\_Type;  
**pragma** Preelaborate(Ada.Strings.Bounded.Hash);
- 8/3 {AI05-0001-1} Equivalent to Strings.Hash (Bounded.To\_String (Key));
- 9/2 {AI95-00302-03} The library function Strings.Unbounded.Hash has the following declaration:
- 10/3 {AI05-0298-1} with Ada.Containers;  
**function** Ada.Strings.Unbounded.Hash (Key : Unbounded\_String)  
**return** Containers.Hash\_Type;  
**pragma** Preelaborate(Ada.Strings.Unbounded.Hash);
- 11/3 {AI05-0001-1} Equivalent to Strings.Hash (To\_String (Key));
- 11.1/3 {AI05-0001-1} {AI05-0298-1} The library function Strings.Hash\_Case\_Insensitive has the following declaration:
- 11.2/3 **with** Ada.Containers;  
**function** Ada.Strings.Hash\_Case\_Insensitive (Key : String)  
**return** Containers.Hash\_Type;  
**pragma** Pure(Ada.Strings.Hash\_Case\_Insensitive);
- 11.3/3 Returns an implementation-defined value which is a function of the value of Key, converted to lower case. If A and B are strings such that Strings.Equal\_Case\_Insensitive (A, B) (see A.4.10) is True, then Hash\_Case\_Insensitive(A) equals Hash\_Case\_Insensitive(B).
- 11.4/3 {AI05-0001-1} {AI05-0298-1} The library function Strings.Fixed.Hash\_Case\_Insensitive has the following declaration:
- 11.5/3 **with** Ada.Containers, Ada.Strings.Hash\_Case\_Insensitive;  
**function** Ada.Strings.Fixed.Hash\_Case\_Insensitive (Key : String)  
**return** Containers.Hash\_Type **renames** Ada.Strings.Hash\_Case\_Insensitive;
- 11.6/3 {AI05-0001-1} {AI05-0298-1} The generic library function Strings.Bounded.Hash\_Case\_Insensitive has the following declaration:
- 11.7/3 **with** Ada.Containers;  
**generic**  
**with package** Bounded **is**  
**new** Ada.Strings.Bounded.Generic\_Bounded\_Length (<>);  
**function** Ada.Strings.Bounded.Hash\_Case\_Insensitive  
(Key : Bounded.Bounded\_String) **return** Containers.Hash\_Type;  
**pragma** Preelaborate(Ada.Strings.Bounded.Hash\_Case\_Insensitive);
- 11.8/3 Equivalent to Strings.Hash\_Case\_Insensitive (Bounded.To\_String (Key));
- 11.9/3 {AI05-0001-1} {AI05-0298-1} The library function Strings.Unbounded.Hash\_Case\_Insensitive has the following declaration:
- 11.10/3 **with** Ada.Containers;  
**function** Ada.Strings.Unbounded.Hash\_Case\_Insensitive  
(Key : Unbounded\_String) **return** Containers.Hash\_Type;  
**pragma** Preelaborate(Ada.Strings.Unbounded.Hash\_Case\_Insensitive);
- 11.11/3 Equivalent to Strings.Hash\_Case\_Insensitive (To\_String (Key));

*Implementation Advice*

{AI95-00302-03} The Hash functions should be good hash functions, returning a wide spread of values for different string values. It should be unlikely for similar strings to return the same value. 12/2

**Implementation Advice:** Strings.Hash should be good a hash function, returning a wide spread of values for different string values, and similar strings should rarely return the same value. 12.a/2

**Ramification:** The other functions are defined in terms of Strings.Hash, so they don't need separate advice in the Annex. 12.b/2

*Extensions to Ada 95*

{AI95-00302-03} The Strings.Hash, Strings.Fixed.Hash, Strings.Bounded.Hash, and Strings.Unbounded.Hash functions are new. 12.c/2

*Extensions to Ada 2005*

{AI05-0001-1} The Strings.Hash\_Case\_Insensitive, Strings.Fixed.Hash\_Case\_Insensitive, Strings.Bounded.Hash\_Case\_Insensitive, and Strings.Unbounded.Hash\_Case\_Insensitive functions are new. 12.d/3

## A.4.10 String Comparison

*Static Semantics*

{AI05-0001-1} {AI05-0286-1} {AI05-0298-1} The library function Strings.Equal\_Case\_Insensitive has the following declaration: 1/3

```
function Ada.Strings.Equal_Case_Insensitive (Left, Right : String)
return Boolean;
pragma Pure(Ada.Strings.Equal_Case_Insensitive);
```

 2/3

Returns True if the strings consist of the same sequence of characters after applying locale-independent simple case folding, as defined by documents referenced in the note in Clause 1 of ISO/IEC 10646:2011. Otherwise, returns False. This function uses the same method as is used to determine whether two identifiers are the same. 3/3

**Discussion:** {AI05-0286-1} For String, this is equivalent to converting to lower case and comparing. Not so for other string types. For Wide\_Strings and Wide\_Wide\_Strings, note that this result is a more accurate comparison than converting the strings to lower case and comparing the results; it is possible that the lower case conversions are the same but this routine will report the strings as different. Additionally, Unicode says that the result of this function will never change for strings made up solely of defined code points; there is no such guarantee for case conversion to lower case. 3.a/3

{AI05-0001-1} {AI05-0248-1} {AI05-0298-1} The library function Strings.Fixed.Equal\_Case\_Insensitive has the following declaration: 4/3

```
with Ada.Strings.Equal_Case_Insensitive;
function Ada.Strings.Fixed.Equal_Case_Insensitive
 (Left, Right : String) return Boolean
 renames Ada.Strings.Equal_Case_Insensitive;
```

 5/3

{AI05-0001-1} {AI05-0248-1} {AI05-0298-1} The generic library function Strings.Bounded.Equal\_Case\_Insensitive has the following declaration: 6/3

```
generic
with package Bounded is
 new Ada.Strings.Bounded.Generic_Bounded_Length (<>);
function Ada.Strings.Bounded.Equal_Case_Insensitive
 (Left, Right : Bounded.Bounded_String) return Boolean;
pragma Preelaborate(Ada.Strings.Bounded.Equal_Case_Insensitive);
```

 7/3

Equivalent to Strings.Equal\_Case\_Insensitive (Bounded.To\_String (Left), Bounded.To\_String (Right)); 8/3

9/3 {AI05-0001-1} {AI05-0248-1} {AI05-0298-1} The library function Strings.Unbounded.Equal\_Case\_Insensitive has the following declaration:

```
10/3 function Ada.Strings.Unbounded.Equal_Case_Insensitive
 (Left, Right : Unbounded_String) return Boolean;
pragma Preelaborate (Ada.Strings.Unbounded.Equal_Case_Insensitive);
```

11/3 Equivalent to Strings.Equal\_Case\_Insensitive (To\_String (Left), To\_String (Right));

12/3 {AI05-0001-1} {AI05-0298-1} The library function Strings.Less\_Case\_Insensitive has the following declaration:

```
13/3 function Ada.Strings.Less_Case_Insensitive (Left, Right : String)
 return Boolean;
pragma Pure (Ada.Strings.Less_Case_Insensitive);
```

14/3 Performs a lexicographic comparison of strings Left and Right, converted to lower case.

15/3 {AI05-0001-1} {AI05-0248-1} {AI05-0298-1} The library function Strings.Fixed.Less\_Case\_Insensitive has the following declaration:

```
16/3 with Ada.Strings.Less_Case_Insensitive;
function Ada.Strings.Fixed.Less_Case_Insensitive
 (Left, Right : String) return Boolean
 renames Ada.Strings.Less_Case_Insensitive;
```

17/3 {AI05-0001-1} {AI05-0248-1} {AI05-0298-1} The generic library function Strings.Bounded.Less\_Case\_Insensitive has the following declaration:

```
18/3 generic
 with package Bounded is
 new Ada.Strings.Bounded.Generic_Bounded_Length (<>);
function Ada.Strings.Bounded.Less_Case_Insensitive
 (Left, Right : Bounded.Bounded_String) return Boolean;
pragma Preelaborate (Ada.Strings.Bounded.Less_Case_Insensitive);
```

19/3 Equivalent to Strings.Less\_Case\_Insensitive (Bounded.To\_String (Left), Bounded.To\_String (Right));

20/3 {AI05-0001-1} {AI05-0248-1} {AI05-0298-1} The library function Strings.Unbounded.Less\_Case\_Insensitive has the following declaration:

```
21/3 function Ada.Strings.Unbounded.Less_Case_Insensitive
 (Left, Right : Unbounded_String) return Boolean;
pragma Preelaborate (Ada.Strings.Unbounded.Less_Case_Insensitive);
```

22/3 Equivalent to Strings.Less\_Case\_Insensitive (To\_String (Left), To\_String (Right));

#### *Extensions to Ada 2005*

22.a/3 {AI05-0001-1} {AI05-0286-1} The Strings.Equal\_Case\_Insensitive, Strings.Fixed.Equal\_Case\_Insensitive, Strings.Bounded.Equal\_Case\_Insensitive, Strings.Unbounded.Equal\_Case\_Insensitive, Strings.Less\_Case\_Insensitive, Strings.Fixed.Less\_Case\_Insensitive, Strings.Bounded.Less\_Case\_Insensitive, Strings.Unbounded.Less\_Case\_Insensitive functions are new.

## A.4.11 String Encoding

1/3 {AI05-0137-2} Facilities for encoding, decoding, and converting strings in various character encoding schemes are provided by packages Strings.UTF\_Encoding, Strings.UTF\_Encoding.Conversions, Strings.UTF\_Encoding.Strings, Strings.UTF\_Encoding.Wide\_Strings, and Strings.UTF\_Encoding.Wide\_Wide\_Strings.

#### *Static Semantics*

2/3 {AI05-0137-2} The encoding library packages have the following declarations:

```

{AI05-0137-2} package Ada.Strings.UTF_Encoding is 3/3
 pragma Pure (UTF_Encoding);
 -- Declarations common to the string encoding packages 4/3
 type Encoding_Scheme is (UTF_8, UTF_16BE, UTF_16LE);
 subtype UTF_String is String; 5/3
 subtype UTF_8_String is String; 6/3
 subtype UTF_16_Wide_String is Wide_String; 7/3
 Encoding_Error : exception; 8/3
 BOM_8 : constant UTF_8_String := 9/3
 Character'Val(16#EF#) &
 Character'Val(16#BB#) &
 Character'Val(16#BF#);
 BOM_16BE : constant UTF_String := 10/3
 Character'Val(16#FE#) &
 Character'Val(16#FF#);
 BOM_16LE : constant UTF_String := 11/3
 Character'Val(16#FF#) &
 Character'Val(16#FE#);
 BOM_16 : constant UTF_16_Wide_String := 12/3
 (1 => Wide_Character'Val(16#FEFF#));
 function Encoding (Item : UTF_String; 13/3
 Default : Encoding_Scheme := UTF_8)
 return Encoding_Scheme;
end Ada.Strings.UTF_Encoding; 14/3
{AI05-0137-2} package Ada.Strings.UTF_Encoding.Conversions is 15/3
 pragma Pure (Conversions);
 -- Conversions between various encoding schemes 16/3
 function Convert (Item : UTF_String;
 Input_Scheme : Encoding_Scheme;
 Output_Scheme : Encoding_Scheme;
 Output_BOM : Boolean := False) return UTF_String;
 function Convert (Item : UTF_String; 17/3
 Input_Scheme : Encoding_Scheme;
 Output_BOM : Boolean := False)
 return UTF_16_Wide_String;
 function Convert (Item : UTF_8_String; 18/3
 Output_BOM : Boolean := False)
 return UTF_16_Wide_String;
 function Convert (Item : UTF_16_Wide_String; 19/3
 Output_Scheme : Encoding_Scheme;
 Output_BOM : Boolean := False) return UTF_String;
 function Convert (Item : UTF_16_Wide_String; 20/3
 Output_BOM : Boolean := False) return UTF_8_String;
end Ada.Strings.UTF_Encoding.Conversions; 21/3
{AI05-0137-2} package Ada.Strings.UTF_Encoding.Strings is 22/3
 pragma Pure (Strings);
 -- Encoding / decoding between String and various encoding schemes 23/3
 function Encode (Item : String;
 Output_Scheme : Encoding_Scheme;
 Output_BOM : Boolean := False) return UTF_String;
 function Encode (Item : String; 24/3
 Output_BOM : Boolean := False) return UTF_8_String;
 function Encode (Item : String; 25/3
 Output_BOM : Boolean := False)
 return UTF_16_Wide_String;

```

```

26/3 function Decode (Item : UTF_String;
 Input_Scheme : Encoding_Scheme) return String;
27/3 function Decode (Item : UTF_8_String) return String;
28/3 function Decode (Item : UTF_16_Wide_String) return String;
29/3 end Ada.Strings.UTF_Encoding.Strings;
30/3 {AI05-0137-2} package Ada.Strings.UTF_Encoding.Wide_Strings is
 pragma Pure (Wide_Strings);
31/3 -- Encoding / decoding between Wide_String and various encoding schemes
 function Encode (Item : Wide_String;
 Output_Scheme : Encoding_Scheme;
 Output_BOM : Boolean := False) return UTF_String;

 return UTF_16_Wide_String;
34/3 function Decode (Item : UTF_String;
 Input_Scheme : Encoding_Scheme) return Wide_String;
35/3 function Decode (Item : UTF_8_String) return Wide_String;
36/3 function Decode (Item : UTF_16_Wide_String) return Wide_String;
37/3 end Ada.Strings.UTF_Encoding.Wide_Strings;
38/3 {AI05-0137-2} package Ada.Strings.UTF_Encoding.Wide_Wide_Strings is
 pragma Pure (Wide_Wide_Strings);
39/3 -- Encoding / decoding between Wide_Wide_String and various encoding schemes
 function Encode (Item : Wide_Wide_String;
 Output_Scheme : Encoding_Scheme;
 Output_BOM : Boolean := False) return UTF_String;
40/3 function Encode (Item : Wide_Wide_String;
 Output_BOM : Boolean := False) return UTF_8_String;
41/3 function Encode (Item : Wide_Wide_String;
 Output_BOM : Boolean := False)
 return UTF_16_Wide_String;
42/3 function Decode (Item : UTF_String;
 Input_Scheme : Encoding_Scheme) return Wide_Wide_String;
43/3 function Decode (Item : UTF_8_String) return Wide_Wide_String;
44/3 function Decode (Item : UTF_16_Wide_String) return Wide_Wide_String;
45/3 end Ada.Strings.UTF_Encoding.Wide_Wide_Strings;
46/3 {AI05-0137-2} {AI05-0262-1} The type Encoding_Scheme defines encoding schemes. UTF_8
corresponds to the UTF-8 encoding scheme defined by Annex D of ISO/IEC 10646. UTF_16BE
corresponds to the UTF-16 encoding scheme defined by Annex C of ISO/IEC 10646 in 8 bit, big-endian
order; and UTF_16LE corresponds to the UTF-16 encoding scheme in 8 bit, little-endian order.
47/3 {AI05-0137-2} The subtype UTF_String is used to represent a String of 8-bit values containing a
sequence of values encoded in one of three ways (UTF-8, UTF-16BE, or UTF-16LE). The subtype
UTF_8_String is used to represent a String of 8-bit values containing a sequence of values encoded in
UTF-8. The subtype UTF_16_Wide_String is used to represent a Wide_String of 16-bit values containing
a sequence of values encoded in UTF-16.
48/3 {AI05-0137-2} {AI05-0262-1} The BOM_8, BOM_16BE, BOM_16LE, and BOM_16 constants
correspond to values used at the start of a string to indicate the encoding.
49/3 {AI05-0262-1} {AI05-0269-1} Each of the Encode functions takes a String, Wide_String, or
Wide_Wide_String Item parameter that is assumed to be an array of unencoded characters. Each of the

```

Convert functions takes a UTF\_String, UTF\_8\_String, or UTF\_16\_String Item parameter that is assumed to contain characters whose position values correspond to a valid encoding sequence according to the encoding scheme required by the function or specified by its Input\_Scheme parameter.

{AI05-0137-2} {AI05-0262-1} {AI05-0269-1} Each of the Convert and Encode functions returns a UTF\_String, UTF\_8\_String, or UTF\_16\_String value whose characters have position values that correspond to the encoding of the Item parameter according to the encoding scheme required by the function or specified by its Output\_Scheme parameter. For UTF\_8, no overlong encoding is returned. A BOM is included at the start of the returned string if the Output\_BOM parameter is set to True. The lower bound of the returned string is 1. 50/3

{AI05-0137-2} {AI05-0262-1} Each of the Decode functions takes a UTF\_String, UTF\_8\_String, or UTF\_16\_String Item parameter which is assumed to contain characters whose position values correspond to a valid encoding sequence according to the encoding scheme required by the function or specified by its Input\_Scheme parameter, and returns the corresponding String, Wide\_String, or Wide\_Wide\_String value. The lower bound of the returned string is 1. 51/3

{AI05-0137-2} {AI05-0262-1} For each of the Convert and Decode functions, an initial BOM in the input that matches the expected encoding scheme is ignored, and a different initial BOM causes Encoding\_Error to be propagated. 52/3

{AI05-0137-2} The exception Encoding\_Error is also propagated in the following situations: 53/3

- By a Decode function when a UTF encoded string contains an invalid encoding sequence. 54/3
- By a Decode function when the expected encoding is UTF-16BE or UTF-16LE and the input string has an odd length. 55/3
- {AI05-0262-1} By a Decode function yielding a String when the decoding of a sequence results in a code point whose value exceeds 16#FF#. 56/3
- By a Decode function yielding a Wide\_String when the decoding of a sequence results in a code point whose value exceeds 16#FFFF#. 57/3
- {AI05-0262-1} By an Encode function taking a Wide\_String as input when an invalid character appears in the input. In particular, the characters whose position is in the range 16#D800# .. 16#DFFF# are invalid because they conflict with UTF-16 surrogate encodings, and the characters whose position is 16#FFFE# or 16#FFFF# are also invalid because they conflict with BOM codes. 58/3

```
{AI05-0137-2} function Encoding (Item : UTF_String;
 Default : Encoding_Scheme := UTF_8)
return Encoding_Scheme; 59/3
```

{AI05-0137-2} {AI05-0269-1} Inspects a UTF\_String value to determine whether it starts with a BOM for UTF-8, UTF-16BE, or UTF\_16LE. If so, returns the scheme corresponding to the BOM; otherwise, returns the value of Default. 60/3

```
{AI05-0137-2} function Convert (Item : UTF_String;
 Input_Scheme : Encoding_Scheme;
 Output_Scheme : Encoding_Scheme;
 Output_BOM : Boolean := False) return UTF_String; 61/3
```

Returns the value of Item (originally encoded in UTF-8, UTF-16LE, or UTF-16BE as specified by Input\_Scheme) encoded in one of these three schemes as specified by Output\_Scheme. 62/3

- 63/3     {AI05-0137-2} **function** Convert (Item                 : UTF\_String;

*Implementation Advice*

{AI05-0137-2} If an implementation supports other encoding schemes, another similar child of Ada.Strings should be defined. 107/3

**Implementation Advice:** If an implementation supports other string encoding schemes, a child of Ada.Strings similar to UTF\_Encoding should be defined. 107.a.1/3

## NOTES

18 {AI05-0137-2} A BOM (Byte-Order Mark, code position 16#FEFF#) can be included in a file or other entity to indicate the encoding; it is skipped when decoding. Typically, only the first line of a file or other entity contains a BOM. When decoding, the Encoding function can be called on the first line to determine the encoding; this encoding will then be used in subsequent calls to Decode to convert all of the lines to an internal format. 108/3

108.a/3 {AI05-0137-2} The packages Strings.UTF\_Encoding, Strings.UTF\_Encoding.Conversions, Strings.UTF\_Encoding.Strings, Strings.UTF\_Encoding.Wide\_Strings, and Strings.UTF\_Encoding.Wide\_Wide\_Strings are new.

## A.5 The Numerics Packages

1 The library package Numerics is the parent of several child units that provide facilities for mathematical computation. One child, the generic package Generic\_Elementary\_Functions, is defined in A.5.1, together with nongeneric equivalents; two others, the package Float\_Random and the generic package Discrete\_Random, are defined in A.5.2. Additional (optional) children are defined in Annex G, “Numerics”.

### Static Semantics

2/1 *This paragraph was deleted.*

```
3/2 {AI95-00388-01} package Ada.Numerics is
 pragma Pure(Numerics);
 Argument_Error : exception;
 Pi : constant :=
 3.14159_26535_89793_23846_26433_83279_50288_41971_69399_37511;
 π : constant := Pi;
 e : constant :=
 2.71828_18284_59045_23536_02874_71352_66249_77572_47093_69996;
end Ada.Numerics;
```

4 The Argument\_Error exception is raised by a subprogram in a child unit of Numerics to signal that one or more of the actual subprogram parameters are outside the domain of the corresponding mathematical function.

### Implementation Permissions

5 The implementation may specify the values of Pi and e to a larger number of significant digits.

5.a **Reason:** 51 digits seem more than adequate for all present computers; converted to binary, the values given above are accurate to more than 160 bits. Nevertheless, the permission allows implementations to accommodate unforeseen hardware advances.

### Extensions to Ada 83

5.b Numerics and its children were not predefined in Ada 83.

### Extensions to Ada 95

5.c/2 {AI95-00388-01} The alternative declaration of  $\pi$  is new.

## A.5.1 Elementary Functions

1 Implementation-defined approximations to the mathematical functions known as the “elementary functions” are provided by the subprograms in Numerics.Generic\_Elementary\_Functions. Nongeneric equivalents of this generic package for each of the predefined floating point types are also provided as children of Numerics.

1.a **Implementation defined:** The accuracy actually achieved by the elementary functions.

### Static Semantics

2 The generic library package Numerics.Generic\_Elementary\_Functions has the following declaration:

```

generic
 type Float_Type is digits <>;
3

package Ada.Numerics.Generic_Elementary_Functions is
 pragma Pure(Generic_Elementary_Functions);

 function Sqrt (X : Float_Type'Base) return Float_Type'Base;
 function Log (X : Float_Type'Base) return Float_Type'Base;
 function Log (X, Base : Float_Type'Base) return Float_Type'Base;
 function Exp (X : Float_Type'Base) return Float_Type'Base;
 function "*" (Left, Right : Float_Type'Base) return Float_Type'Base;
4

 function Sin (X : Float_Type'Base) return Float_Type'Base;
 function Sin (X, Cycle : Float_Type'Base) return Float_Type'Base;
 function Cos (X : Float_Type'Base) return Float_Type'Base;
 function Cos (X, Cycle : Float_Type'Base) return Float_Type'Base;
 function Tan (X : Float_Type'Base) return Float_Type'Base;
 function Tan (X, Cycle : Float_Type'Base) return Float_Type'Base;
 function Cot (X : Float_Type'Base) return Float_Type'Base;
 function Cot (X, Cycle : Float_Type'Base) return Float_Type'Base;
5

 function Arcsin (X : Float_Type'Base) return Float_Type'Base;
 function Arcsin (X, Cycle : Float_Type'Base) return Float_Type'Base;
 function Arccos (X : Float_Type'Base) return Float_Type'Base;
 function Arccos (X, Cycle : Float_Type'Base) return Float_Type'Base;
 function Arctan (Y : Float_Type'Base;
 X : Float_Type'Base := 1.0)
 return Float_Type'Base;
 function Arctan (Y : Float_Type'Base;
 X : Float_Type'Base := 1.0;
 Cycle : Float_Type'Base) return Float_Type'Base;
 function Arccot (X : Float_Type'Base;
 Y : Float_Type'Base := 1.0)
 return Float_Type'Base;
 function Arccot (X : Float_Type'Base;
 Y : Float_Type'Base := 1.0;
 Cycle : Float_Type'Base) return Float_Type'Base;
6

 function Sinh (X : Float_Type'Base) return Float_Type'Base;
 function Cosh (X : Float_Type'Base) return Float_Type'Base;
 function Tanh (X : Float_Type'Base) return Float_Type'Base;
 function Coth (X : Float_Type'Base) return Float_Type'Base;
 function Arcsinh (X : Float_Type'Base) return Float_Type'Base;
 function Arccosh (X : Float_Type'Base) return Float_Type'Base;
 function Arctanh (X : Float_Type'Base) return Float_Type'Base;
 function Arccoth (X : Float_Type'Base) return Float_Type'Base;
7

end Ada.Numerics.Generic_Elementary_Functions;
8

```

{8652/0020} {AI95-00126-01} The library package Numerics.Elementary\_Functions is declared pure and defines the same subprograms as Numerics.Generic\_Elementary\_Functions, except that the predefined type Float is systematically substituted for Float\_Type'Base throughout. Nongeneric equivalents of Numerics.Generic\_Elementary\_Functions for each of the other predefined floating point types are defined similarly, with the names Numerics.Short\_Elementary\_Functions, Numerics.Long\_Elementary\_Functions, etc.

**Reason:** The nongeneric equivalents are provided to allow the programmer to construct simple mathematical applications without being required to understand and use generics. 9.a

The functions have their usual mathematical meanings. When the Base parameter is specified, the Log function computes the logarithm to the given base; otherwise, it computes the natural logarithm. When the Cycle parameter is specified, the parameter X of the forward trigonometric functions (Sin, Cos, Tan, and Cot) and the results of the inverse trigonometric functions (Arcsin, Arccos, Arctan, and Arccot) are measured in units such that a full cycle of revolution has the given value; otherwise, they are measured in radians. 10

11 The computed results of the mathematically multivalued functions are rendered single-valued by the following conventions, which are meant to imply the principal branch:

- 12 • The results of the Sqrt and Arccosh functions and that of the exponentiation operator are nonnegative.
- 13 • The result of the Arcsin function is in the quadrant containing the point (1.0,  $x$ ), where  $x$  is the value of the parameter X. This quadrant is I or IV; thus, the range of the Arcsin function is approximately  $-\pi/2.0$  to  $\pi/2.0$  ( $-\text{Cycle}/4.0$  to  $\text{Cycle}/4.0$ , if the parameter Cycle is specified).
- 14 • The result of the Arccos function is in the quadrant containing the point ( $x$ , 1.0), where  $x$  is the value of the parameter X. This quadrant is I or II; thus, the Arccos function ranges from 0.0 to approximately  $\pi$  ( $\text{Cycle}/2.0$ , if the parameter Cycle is specified).
- 15 • The results of the Arctan and Arccot functions are in the quadrant containing the point ( $x$ ,  $y$ ), where  $x$  and  $y$  are the values of the parameters X and Y, respectively. This may be any quadrant (I through IV) when the parameter X (resp., Y) of Arctan (resp., Arccot) is specified, but it is restricted to quadrants I and IV (resp., I and II) when that parameter is omitted. Thus, the range when that parameter is specified is approximately  $-\pi$  to  $\pi$  ( $-\text{Cycle}/2.0$  to  $\text{Cycle}/2.0$ , if the parameter Cycle is specified); when omitted, the range of Arctan (resp., Arccot) is that of Arcsin (resp., Arccos), as given above. When the point ( $x$ ,  $y$ ) lies on the negative x-axis, the result approximates
  - 16 •  $\pi$  (resp.,  $-\pi$ ) when the sign of the parameter Y is positive (resp., negative), if Float\_Type'Signed\_Zeros is True;
  - 17 •  $\pi$ , if Float\_Type'Signed\_Zeros is False.

18 (In the case of the inverse trigonometric functions, in which a result lying on or near one of the axes may not be exactly representable, the approximation inherent in computing the result may place it in an adjacent quadrant, close to but on the wrong side of the axis.)

#### *Dynamic Semantics*

19 The exception Numerics.Argument\_Error is raised, signaling a parameter value outside the domain of the corresponding mathematical function, in the following cases:

- 20 • by any forward or inverse trigonometric function with specified cycle, when the value of the parameter Cycle is zero or negative;
- 21 • by the Log function with specified base, when the value of the parameter Base is zero, one, or negative;
- 22 • by the Sqrt and Log functions, when the value of the parameter X is negative;
- 23 • by the exponentiation operator, when the value of the left operand is negative or when both operands have the value zero;
- 24 • by the Arcsin, Arccos, and Arctanh functions, when the absolute value of the parameter X exceeds one;
- 25 • by the Arctan and Arccot functions, when the parameters X and Y both have the value zero;
- 26 • by the Arccosh function, when the value of the parameter X is less than one; and
- 27 • by the Arccoth function, when the absolute value of the parameter X is less than one.

28 The exception Constraint\_Error is raised, signaling a pole of the mathematical function (analogous to dividing by zero), in the following cases, provided that Float\_Type'Machine\_Overflows is True:

- 29 • by the Log, Cot, and Coth functions, when the value of the parameter X is zero;
- 30 • by the exponentiation operator, when the value of the left operand is zero and the value of the exponent is negative;

- by the Tan function with specified cycle, when the value of the parameter *X* is an odd multiple of the quarter cycle; 31
  - by the Cot function with specified cycle, when the value of the parameter *X* is zero or a multiple of the half cycle; and 32
  - by the Arctanh and Arccoth functions, when the absolute value of the parameter *X* is one. 33
- [Constraint\_Error can also be raised when a finite result overflows (see G.2.4); this may occur for parameter values sufficiently *near* poles, and, in the case of some of the functions, for parameter values with sufficiently large magnitudes.] When Float\_Type'Machine\_Overflows is False, the result at poles is unspecified. 34
- Reason:** The purpose of raising Constraint\_Error (rather than Numerics.Argument\_Error) at the poles of a function, when Float\_Type'Machine\_Overflows is True, is to provide continuous behavior as the actual parameters of the function approach the pole and finally reach it. 34.a
- Discussion:** It is anticipated that an Ada binding to IEC 559:1989 will be developed in the future. As part of such a binding, the Machine\_Overflows attribute of a conformant floating point type will be specified to yield False, which will permit both the predefined arithmetic operations and implementations of the elementary functions to deliver signed infinities (and set the overflow flag defined by the binding) instead of raising Constraint\_Error in overflow situations, when traps are disabled. Similarly, it is appropriate for the elementary functions to deliver signed infinities (and set the zero-divide flag defined by the binding) instead of raising Constraint\_Error at poles, when traps are disabled. Finally, such a binding should also specify the behavior of the elementary functions, when sensible, given parameters with infinite values. 34.b
- When one parameter of a function with multiple parameters represents a pole and another is outside the function's domain, the latter takes precedence (i.e., Numerics.Argument\_Error is raised). 35
- Implementation Requirements*
- In the implementation of Numerics.Generic\_Elementary\_Functions, the range of intermediate values allowed during the calculation of a final result shall not be affected by any range constraint of the subtype Float\_Type. 36
- Implementation Note:** Implementations of Numerics.Generic\_Elementary\_Functions written in Ada should therefore avoid declaring local variables of subtype Float\_Type; the subtype Float\_Type'Base should be used instead. 36.a
- In the following cases, evaluation of an elementary function shall yield the *prescribed result*, provided that the preceding rules do not call for an exception to be raised: 37
- When the parameter *X* has the value zero, the Sqrt, Sin, Arcsin, Tan, Sinh, Arcsinh, Tanh, and Arctanh functions yield a result of zero, and the Exp, Cos, and Cosh functions yield a result of one. 38
  - When the parameter *X* has the value one, the Sqrt function yields a result of one, and the Log, Arccos, and Arccosh functions yield a result of zero. 39
  - When the parameter *Y* has the value zero and the parameter *X* has a positive value, the Arctan and Arccot functions yield a result of zero. 40
  - The results of the Sin, Cos, Tan, and Cot functions with specified cycle are exact when the mathematical result is zero; those of the first two are also exact when the mathematical result is  $\pm 1.0$ . 41
  - Exponentiation by a zero exponent yields the value one. Exponentiation by a unit exponent yields the value of the left operand. Exponentiation of the value one yields the value one. Exponentiation of the value zero yields the value zero. 42
- Other accuracy requirements for the elementary functions, which apply only in implementations conforming to the Numerics Annex, and then only in the “strict” mode defined there (see G.2), are given in G.2.4. 43

- 44 When `Float_Type'Signed_Zeros` is `True`, the sign of a zero result shall be as follows:
- 45 • A prescribed zero result delivered *at the origin* by one of the odd functions (`Sin`, `Arcsin`, `Sinh`, `Arcsinh`, `Tan`, `Arctan` or `Arccot` as a function of `Y` when `X` is fixed and positive, `Tanh`, and `Arctanh`) has the sign of the parameter `X` (`Y`, in the case of `Arctan` or `Arccot`).
  - 46 • A prescribed zero result delivered by one of the odd functions *away from the origin*, or by some other elementary function, has an implementation-defined sign.
- 46.a **Implementation defined:** The sign of a zero result from some of the operators or functions in `Numerics.Generic_Elementary_Functions`, when `Float_Type'Signed_Zeros` is `True`.
- 47 • [A zero result that is not a prescribed result (i.e., one that results from rounding or underflow) has the correct mathematical sign.]
- 47.a **Reason:** This is a consequence of the rules specified in IEC 559:1989 as they apply to underflow situations with traps disabled.

*Implementation Permissions*

- 48 The nongeneric equivalent packages may, but need not, be actual instantiations of the generic package for the appropriate predefined type.

*Wording Changes from Ada 83*

- 48.a The semantics of `Numerics.Generic_Elementary_Functions` differs from `Generic_Elementary_Functions` as defined in ISO/IEC DIS 11430 (for Ada 83) in the following ways:
- 48.b • The generic package is a child unit of the package defining the `Argument_Error` exception.
  - 48.c • DIS 11430 specified names for the nongeneric equivalents, if provided. Here, those nongeneric equivalents are required.
  - 48.d • Implementations are not allowed to impose an optional restriction that the generic actual parameter associated with `Float_Type` be unconstrained. (In view of the ability to declare variables of subtype `Float_Type'Base` in implementations of `Numerics.Generic_Elementary_Functions`, this flexibility is no longer needed.)
  - 48.e • The sign of a prescribed zero result at the origin of the odd functions is specified, when `Float_Type'Signed_Zeros` is `True`. This conforms with recommendations of Kahan and other numerical analysts.
  - 48.f • The dependence of `Arctan` and `Arccot` on the sign of a parameter value of zero is tied to the value of `Float_Type'Signed_Zeros`.
  - 48.g • `Sqrt` is prescribed to yield a result of one when its parameter has the value one. This guarantee makes it easier to achieve certain prescribed results of the complex elementary functions (see G.1.2, “Complex Elementary Functions”).
  - 48.h • Conformance to accuracy requirements is conditional.

*Wording Changes from Ada 95*

- 48.i/2 `{8652/0020}` `{A195-00126-01}` **Corrigendum:** Explicitly stated that the nongeneric equivalents of `Generic_Elementary_Functions` are pure.

## A.5.2 Random Number Generation

- 1 [Facilities for the generation of pseudo-random floating point numbers are provided in the package `Numerics.Float_Random`; the generic package `Numerics.Discrete_Random` provides similar facilities for the generation of pseudo-random integers and pseudo-random values of enumeration types. For brevity, pseudo-random values of any of these types are called *random numbers*.
- 2 Some of the facilities provided are basic to all applications of random numbers. These include a limited private type each of whose objects serves as the generator of a (possibly distinct) sequence of random numbers; a function to obtain the “next” random number from a given sequence of random numbers (that

is, from its generator); and subprograms to initialize or reinitialize a given generator to a time-dependent state or a state denoted by a single integer.

Other facilities are provided specifically for advanced applications. These include subprograms to save and restore the state of a given generator; a private type whose objects can be used to hold the saved state of a generator; and subprograms to obtain a string representation of a given generator state, or, given such a string representation, the corresponding state.]

**Discussion:** These facilities support a variety of requirements ranging from repeatable sequences (for debugging) to unique sequences in each execution of a program.

#### Static Semantics

The library package `Numerics.Float_Random` has the following declaration:

```

package Ada.Numerics.Float_Random is
 -- Basic facilities
 type Generator is limited private;
 subtype Uniformly_Distributed is Float range 0.0 .. 1.0;
 function Random (Gen : Generator) return Uniformly_Distributed;
 procedure Reset (Gen : in Generator;
 Initiator : in Integer);
 procedure Reset (Gen : in Generator);
 -- Advanced facilities
 type State is private;
 procedure Save (Gen : in Generator;
 To_State : out State);
 procedure Reset (Gen : in Generator;
 From_State : in State);
 Max_Image_Width : constant := implementation-defined integer value;
 function Image (Of_State : State) return String;
 function Value (Coded_State : String) return State;
private
 ... -- not specified by the language
end Ada.Numerics.Float_Random;

```

{AI95-00360-01} The type `Generator` needs finalization (see 7.6).

The generic library package `Numerics.Discrete_Random` has the following declaration:

```

generic
 type Result_Subtype is (<>);
package Ada.Numerics.Discrete_Random is
 -- Basic facilities
 type Generator is limited private;
 function Random (Gen : Generator) return Result_Subtype;
 procedure Reset (Gen : in Generator;
 Initiator : in Integer);
 procedure Reset (Gen : in Generator);
 -- Advanced facilities
 type State is private;
 procedure Save (Gen : in Generator;
 To_State : out State);
 procedure Reset (Gen : in Generator;
 From_State : in State);
 Max_Image_Width : constant := implementation-defined integer value;

```

- 26           **function** Image (Of\_State     : State) **return** String;  
               **function** Value (Coded\_State : String) **return** State;
- 27       **private**  
           ... -- *not specified by the language*  
       **end** Ada.Numerics.Discrete\_Random;
- 27.a           **Implementation defined:** The value of Numerics.Float\_Random.Max\_Image\_Width.
- 27.b           **Implementation defined:** The value of Numerics.Discrete\_Random.Max\_Image\_Width.
- 27.c/1          **Implementation Note:** {8652/0097} {AI95-00115-01} The following is a possible implementation of the private part of Numerics.Float\_Random (assuming the presence of “**with** Ada.Finalization;” as a context clause):
- 27.d           **type** State **is** ...;  
               **type** Access\_State **is access** State;  
               **type** Generator **is new** Finalization.Limited\_Controlled **with**  
                   **record**  
                     S : Access\_State := **new** State'(...);  
                   **end record**;  
               **procedure** Finalize (G : **in out** Generator);
- 27.d.1/2        {8652/0097} {AI95-00115-01} {AI95-00344-01} Numerics.Discrete\_Random.Generator also can be implemented this way.
- 27.e           Clearly some level of indirection is required in the implementation of a Generator, since the parameter mode is **in** for all operations on a Generator. For this reason, Numerics.Float\_Random and Numerics.Discrete\_Random cannot be declared pure.
- 27.1/2        {AI95-00360-01} The type Generator needs finalization (see 7.6) in every instantiation of Numerics.Discrete\_Random.
- 28           An object of the limited private type Generator is associated with a sequence of random numbers. Each generator has a hidden (internal) state, which the operations on generators use to determine the position in the associated sequence. All generators are implicitly initialized to an unspecified state that does not vary from one program execution to another; they may also be explicitly initialized, or reinitialized, to a time-dependent state, to a previously saved state, or to a state uniquely denoted by an integer value.
- 28.a           **Discussion:** The repeatability provided by the implicit initialization may be exploited for testing or debugging purposes.
- 29/3        {AI05-0280-1} An object of the private type State can be used to hold the internal state of a generator. Such objects are only needed if the application is designed to save and restore generator states or to examine or manufacture them. The implicit initial value of type State corresponds to the implicit initial value of all generators.
- 29.a/3        **Discussion:** {AI05-0280-1} All generators are implicitly initialized to the same unchanging value, and using Reset on a default initialized object of type State will produce a generator with that same value.
- 30           The operations on generators affect the state and therefore the future values of the associated sequence. The semantics of the operations on generators and states are defined below.
- 31           **function** Random (Gen : Generator) **return** Uniformly\_Distributed;  
               **function** Random (Gen : Generator) **return** Result\_Subtype;
- 32           Obtains the “next” random number from the given generator, relative to its current state, according to an implementation-defined algorithm. The result of the function in Numerics.Float\_Random is delivered as a value of the subtype Uniformly\_Distributed, which is a subtype of the predefined type Float having a range of 0.0 .. 1.0. The result of the function in an instantiation of Numerics.Discrete\_Random is delivered as a value of the generic formal subtype Result\_Subtype.
- 32.a/2        *This paragraph was deleted.*
- 32.a.1/2       **Discussion:** The algorithm is the subject of a Documentation Requirement, so we don't separately summarize this implementation-defined item.
- 32.b           **Reason:** The requirement for a level of indirection in accessing the internal state of a generator arises from the desire to make Random a function, rather than a procedure.

```

procedure Reset (Gen : in Generator;
 Initiator : in Integer);
procedure Reset (Gen : in Generator);

```

Sets the state of the specified generator to one that is an unspecified function of the value of the parameter Initiator (or to a time-dependent state, if only a generator parameter is specified). The latter form of the procedure is known as the *time-dependent Reset procedure*.

**Implementation Note:** The time-dependent Reset procedure can be implemented by mapping the current time and date as determined by the system clock into a state, but other implementations are possible. For example, a white-noise generator or a radioactive source can be used to generate time-dependent states.

```

procedure Save (Gen : in Generator;
 To_State : out State);
procedure Reset (Gen : in Generator;
 From_State : in State);

```

Save obtains the current state of a generator. Reset gives a generator the specified state. A generator that is reset to a state previously obtained by invoking Save is restored to the state it had when Save was invoked.

```

function Image (Of_State : State) return String;
function Value (Coded_State : String) return State;

```

Image provides a representation of a state coded (in an implementation-defined way) as a string whose length is bounded by the value of Max\_Image\_Width. Value is the inverse of Image: Value(Image(S)) = S for each state S that can be obtained from a generator by invoking Save.

**Implementation defined:** The string representation of a random number generator's state.

#### *Dynamic Semantics*

Instantiation of Numerics.Discrete\_Random with a subtype having a null range raises Constraint\_Error. 39

*This paragraph was deleted. {8652/0050} {AI95-00089}* 40/1

#### *Bounded (Run-Time) Errors*

{8652/0050} {AI95-00089} It is a bounded error to invoke Value with a string that is not the image of any generator state. If the error is detected, Constraint\_Error or Program\_Error is raised. Otherwise, a call to Reset with the resulting state will produce a generator such that calls to Random with this generator will produce a sequence of values of the appropriate subtype, but which might not be random in character. That is, the sequence of values might not fulfill the implementation requirements of this subclause. 40.1/1

#### *Implementation Requirements*

A sufficiently long sequence of random numbers obtained by successive calls to Random is approximately uniformly distributed over the range of the result subtype. 41

The Random function in an instantiation of Numerics.Discrete\_Random is guaranteed to yield each value in its result subtype in a finite number of calls, provided that the number of such values does not exceed 2<sup>15</sup>. 42

Other performance requirements for the random number generator, which apply only in implementations conforming to the Numerics Annex, and then only in the “strict” mode defined there (see G.2), are given in G.2.5. 43

#### *Documentation Requirements*

No one algorithm for random number generation is best for all applications. To enable the user to determine the suitability of the random number generators for the intended application, the implementation shall describe the algorithm used and shall give its period, if known exactly, or a lower 44

bound on the period, if the exact period is unknown. Periods that are so long that the periodicity is unobservable in practice can be described in such terms, without giving a numerical bound.

44.a/2 **Documentation Requirement:** The algorithm used for random number generation, including a description of its period.

45 The implementation also shall document the minimum time interval between calls to the time-dependent Reset procedure that are guaranteed to initiate different sequences, and it shall document the nature of the strings that Value will accept without raising Constraint\_Error.

45.a/2 *This paragraph was deleted.*

45.b/2 **Documentation Requirement:** The minimum time interval between calls to the time-dependent Reset procedure that is guaranteed to initiate different random number sequences.

*Implementation Advice*

46 Any storage associated with an object of type Generator should be reclaimed on exit from the scope of the object.

46.a.1/2 **Implementation Advice:** Any storage associated with an object of type Generator of the random number packages should be reclaimed on exit from the scope of the object.

46.a **Ramification:** A level of indirection is implicit in the semantics of the operations, given that they all take parameters of mode **in**. This implies that the full type of Generator probably should be a controlled type, with appropriate finalization to reclaim any heap-allocated storage.

47 If the generator period is sufficiently long in relation to the number of distinct initiator values, then each possible value of Initiator passed to Reset should initiate a sequence of random numbers that does not, in a practical sense, overlap the sequence initiated by any other value. If this is not possible, then the mapping between initiator values and generator states should be a rapidly varying function of the initiator value.

47.a/2 **Implementation Advice:** Each value of Initiator passed to Reset for the random number packages should initiate a distinct sequence of random numbers, or, if that is not possible, be at least a rapidly varying function of the initiator value.

NOTES

48 19 If two or more tasks are to share the same generator, then the tasks have to synchronize their access to the generator as for any shared variable (see 9.10).

49 20 Within a given implementation, a repeatable random number sequence can be obtained by relying on the implicit initialization of generators or by explicitly initializing a generator with a repeatable initiator value. Different sequences of random numbers can be obtained from a given generator in different program executions by explicitly initializing the generator to a time-dependent state.

50 21 A given implementation of the Random function in Numerics.Float\_Random may or may not be capable of delivering the values 0.0 or 1.0. Portable applications should assume that these values, or values sufficiently close to them to behave indistinguishably from them, can occur. If a sequence of random integers from some fixed range is needed, the application should use the Random function in an appropriate instantiation of Numerics.Discrete\_Random, rather than transforming the result of the Random function in Numerics.Float\_Random. However, some applications with unusual requirements, such as for a sequence of random integers each drawn from a different range, will find it more convenient to transform the result of the floating point Random function. For  $M \geq 1$ , the expression

51 
$$\text{Integer}(\text{Float}(M) * \text{Random}(G)) \bmod M$$

52 transforms the result of Random(G) to an integer uniformly distributed over the range 0 .. M-1; it is valid even if Random delivers 0.0 or 1.0. Each value of the result range is possible, provided that M is not too large. Exponentially distributed (floating point) random numbers with mean and standard deviation 1.0 can be obtained by the transformation

53/2 
$$\{AI95-00434-01\} \quad -\text{Log}(\text{Random}(G) + \text{Float}'\text{Model\_Small})$$

54 where Log comes from Numerics.Elementary\_Functions (see A.5.1); in this expression, the addition of Float'Model\_Small avoids the exception that would be raised were Log to be given the value zero, without affecting the result (in most implementations) when Random returns a nonzero value.

## Examples

*Example of a program that plays a simulated dice game:*

55

```

with Ada.Numerics.Discrete_Random;
procedure Dice_Game is
 subtype Die is Integer range 1 .. 6;
 subtype Dice is Integer range 2*Die'First .. 2*Die'Last;
 package Random_Die is new Ada.Numerics.Discrete_Random (Die);
 use Random_Die;
 G : Generator;
 D : Dice;
begin
 Reset (G); -- Start the generator in a unique state in each run
 loop
 -- Roll a pair of dice; sum and process the results
 D := Random(G) + Random(G);
 ...
 end loop;
end Dice_Game;

```

56

*Example of a program that simulates coin tosses:*

57

```

with Ada.Numerics.Discrete_Random;
procedure Flip_A_Coin is
 type Coin is (Heads, Tails);
 package Random_Coin is new Ada.Numerics.Discrete_Random (Coin);
 use Random_Coin;
 G : Generator;
begin
 Reset (G); -- Start the generator in a unique state in each run
 loop
 -- Toss a coin and process the result
 case Random(G) is
 when Heads =>
 ...
 when Tails =>
 ...
 end case;
 ...
 end loop;
end Flip_A_Coin;

```

58

59 *Example of a parallel simulation of a physical system, with a separate generator of event probabilities in each task:*

```
60 with Ada.Numerics.Float_Random;
 procedure Parallel_Simulation is
 use Ada.Numerics.Float_Random;
 task type Worker is
 entry Initialize_Generator (Initiator : in Integer);
 ...
 end Worker;
 W : array (1 .. 10) of Worker;
 task body Worker is
 G : Generator;
 Probability_Of_Event : Uniformly_Distributed;
 begin
 accept Initialize_Generator (Initiator : in Integer) do
 Reset (G, Initiator);
 end Initialize_Generator;
 loop
 ...
 Probability_Of_Event := Random(G);
 ...
 end loop;
 end Worker;
begin
 -- Initialize the generators in the Worker tasks to different states
 for I in W'Range loop
 W(I).Initialize_Generator (I);
 end loop;
 ... -- Wait for the Worker tasks to terminate
end Parallel_Simulation;
```

#### NOTES

61 22 *Notes on the last example:* Although each Worker task initializes its generator to a different state, those states will be the same in every execution of the program. The generator states can be initialized uniquely in each program execution by instantiating `Ada.Numerics.Discrete_Random` for the type `Integer` in the main procedure, resetting the generator obtained from that instance to a time-dependent state, and then using random integers obtained from that generator to initialize the generators in each Worker task.

#### *Incompatibilities With Ada 95*

61.a/2 {A195-00360-01} **Amendment Correction:** Type `Generator` in `Numerics.Float_Random` and in an instance of `Numerics.Discrete_Random` is defined to need finalization. If the restriction `No_Nested_Finalization` (see D.7) applies to the partition, and `Generator` does not have a controlled part, it will not be allowed in local objects in Ada 2005 whereas it would be allowed in original Ada 95. Such code is not portable, as another Ada compiler may have a controlled part in `Generator`, and thus would be illegal.

#### *Wording Changes from Ada 95*

61.b/3 {8652/0050} {A195-00089-01} {A105-0005-1} **Corrigendum:** Made the passing of an incorrect `Image` of a generator a bounded error, as it might not be practical to check for problems (if a generator consists of several related values).

#### *Wording Changes from Ada 2005*

61.c/3 {A105-0280-1} **Correction:** Specified the implicit initial value for (sub)type `State`. This was unspecified in Ada 95 and Ada 2005, so a program depending on some other initial value is very unlikely and certainly was not portable. An implementation can use default expressions, `aspect Default_Value`, or `aspect Default_Component_Value` to keep the representation of the type unchanged while meeting this new requirement.

## A.5.3 Attributes of Floating Point Types

### *Static Semantics*

1 The following *representation-oriented attributes* are defined for every subtype `S` of a floating point type `T`.

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |    |      |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----|------|
| S'Machine_Radix                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 2  |      |
| Yields the radix of the hardware representation of the type $T$ . The value of this attribute is of the type <i>universal_integer</i> .                                                                                                                                                                                                                                                                                                                                                                         |    |      |
| The values of other representation-oriented attributes of a floating point subtype, and of the “primitive function” attributes of a floating point subtype described later, are defined in terms of a particular representation of nonzero values called the <i>canonical form</i> . The canonical form (for the type $T$ ) is the form                                                                                                                                                                         |    |      |
| $\pm \textit{mantissa} \cdot T\textit{Machine\_Radix}^{\textit{exponent}}$                                                                                                                                                                                                                                                                                                                                                                                                                                      |    |      |
| where                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |    |      |
| <ul style="list-style-type: none"> <li>• <i>mantissa</i> is a fraction in the number base <math>T\textit{Machine\_Radix}</math>, the first digit of which is nonzero, and</li> <li>• <i>exponent</i> is an integer.</li> </ul>                                                                                                                                                                                                                                                                                  | 4  |      |
| S'Machine_Mantissa                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | 6  |      |
| Yields the largest value of $p$ such that every value expressible in the canonical form (for the type $T$ ), having a $p$ -digit <i>mantissa</i> and an <i>exponent</i> between $T\textit{Machine\_Emin}$ and $T\textit{Machine\_Emax}$ , is a machine number (see 3.5.7) of the type $T$ . This attribute yields a value of the type <i>universal_integer</i> .                                                                                                                                                |    |      |
| <b>Ramification:</b> Values of a type held in an extended register are, in general, not machine numbers of the type, since they cannot be expressed in the canonical form with a sufficiently short <i>mantissa</i> .                                                                                                                                                                                                                                                                                           |    | 6.a  |
| S'Machine_Emin                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 7  |      |
| Yields the smallest (most negative) value of <i>exponent</i> such that every value expressible in the canonical form (for the type $T$ ), having a <i>mantissa</i> of $T\textit{Machine\_Mantissa}$ digits, is a machine number (see 3.5.7) of the type $T$ . This attribute yields a value of the type <i>universal_integer</i> .                                                                                                                                                                              |    |      |
| S'Machine_Emax                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 8  |      |
| Yields the largest (most positive) value of <i>exponent</i> such that every value expressible in the canonical form (for the type $T$ ), having a <i>mantissa</i> of $T\textit{Machine\_Mantissa}$ digits, is a machine number (see 3.5.7) of the type $T$ . This attribute yields a value of the type <i>universal_integer</i> .                                                                                                                                                                               |    |      |
| <b>Ramification:</b> Note that the above definitions do not determine unique values for the representation-oriented attributes of floating point types. The implementation may choose any set of values that collectively satisfies the definitions.                                                                                                                                                                                                                                                            |    | 8.a  |
| S'Denorm                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | 9  |      |
| Yields the value True if every value expressible in the form $\pm \textit{mantissa} \cdot T\textit{Machine\_Radix}^{T\textit{Machine\_Emin}}$ where <i>mantissa</i> is a nonzero $T\textit{Machine\_Mantissa}$ -digit fraction in the number base $T\textit{Machine\_Radix}$ , the first digit of which is zero, is a machine number (see 3.5.7) of the type $T$ ; yields the value False otherwise. The value of this attribute is of the predefined type Boolean.                                             |    |      |
| The values described by the formula in the definition of S'Denorm are called <i>denormalized numbers</i> . A nonzero machine number that is not a denormalized number is a <i>normalized number</i> . A normalized number $x$ of a given type $T$ is said to be <i>represented in canonical form</i> when it is expressed in the canonical form (for the type $T$ ) with a <i>mantissa</i> having $T\textit{Machine\_Mantissa}$ digits; the resulting form is the <i>canonical-form representation</i> of $x$ . |    | 10   |
| <b>Discussion:</b> The intent is that S'Denorm be True when such denormalized numbers exist and are generated in the circumstances defined by IEC 559:1989, though the latter requirement is not formalized here.                                                                                                                                                                                                                                                                                               |    | 10.a |
| S'Machine_Rounds                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 11 |      |
| Yields the value True if rounding is performed on inexact results of every predefined operation that yields a result of the type $T$ ; yields the value False otherwise. The value of this attribute is of the predefined type Boolean.                                                                                                                                                                                                                                                                         |    |      |

- 11.a **Discussion:** It is difficult to be more precise about what it means to round the result of a predefined operation. If the implementation does not use extended registers, so that every arithmetic result is necessarily a machine number, then rounding seems to imply two things:
- 11.b
- S'Model\_Mantissa = S'Machine\_Mantissa, so that operand preperurbation never occurs;
- 11.c
- when the exact mathematical result is not a machine number, the result of a predefined operation must be the nearer of the two adjacent machine numbers.
- 11.d Technically, this attribute should yield False when extended registers are used, since a few computed results will cross over the half-way point as a result of double rounding, if and when a value held in an extended register has to be reduced in precision to that of the machine numbers. It does not seem desirable to preclude the use of extended registers when S'Machine\_Rounds could otherwise be True.
- 12 S'Machine\_Overflows  
Yields the value True if overflow and divide-by-zero are detected and reported by raising Constraint\_Error for every predefined operation that yields a result of the type *T*; yields the value False otherwise. The value of this attribute is of the predefined type Boolean.
- 13 S'Signed\_Zeros  
Yields the value True if the hardware representation for the type *T* has the capability of representing both positively and negatively signed zeros, these being generated and used by the predefined operations of the type *T* as specified in IEC 559:1989; yields the value False otherwise. The value of this attribute is of the predefined type Boolean.
- 14 For every value *x* of a floating point type *T*, the *normalized exponent* of *x* is defined as follows:
- 15
- the normalized exponent of zero is (by convention) zero;
- 16
- for nonzero *x*, the normalized exponent of *x* is the unique integer *k* such that  $TMachine\_Radix^{k-1} \leq |x| < TMachine\_Radix^k$ .
- 16.a **Ramification:** The normalized exponent of a normalized number *x* is the value of *exponent* in the canonical-form representation of *x*.
- 16.b The normalized exponent of a denormalized number is less than the value of *TMachine\_Emin*.
- 17 The following *primitive function attributes* are defined for any subtype *S* of a floating point type *T*.
- 18 S'Exponent S'Exponent denotes a function with the following specification:
- 19
- ```
function S'Exponent (X : T)
return universal_integer
```
- 20 The function yields the normalized exponent of *X*.
- 21 S'Fraction S'Fraction denotes a function with the following specification:
- 22
- ```
function S'Fraction (X : T)
return T
```
- 23 The function yields the value  $X \cdot TMachine\_Radix^{-k}$ , where *k* is the normalized exponent of *X*. A zero result[, which can only occur when *X* is zero,] has the sign of *X*.
- 23.a **Discussion:** Informally, when *X* is a normalized number, the result is the value obtained by replacing the *exponent* by zero in the canonical-form representation of *X*.
- 23.b **Ramification:** Except when *X* is zero, the magnitude of the result is greater than or equal to the reciprocal of *TMachine\_Radix* and less than one; consequently, the result is always a normalized number, even when *X* is a denormalized number.
- 23.c **Implementation Note:** When *X* is a denormalized number, the result is the value obtained by replacing the *exponent* by zero in the canonical-form representation of the result of scaling *X* up sufficiently to normalize it.
- 24 S'Compose S'Compose denotes a function with the following specification:
- 25
- ```
function S'Compose (Fraction : T;
                  Exponent : universal_integer)
return T
```
- 26 Let *v* be the value $Fraction \cdot TMachine_Radix^{Exponent-k}$, where *k* is the normalized exponent of *Fraction*. If *v* is a machine number of the type *T*, or if $|v| \geq TModel_Small$, the function

yields v ; otherwise, it yields either one of the machine numbers of the type T adjacent to v . `Constraint_Error` is optionally raised if v is outside the base range of S . A zero result has the sign of `Fraction` when `S'Signed_Zeros` is `True`.

Discussion: Informally, when `Fraction` and v are both normalized numbers, the result is the value obtained by replacing the *exponent* by *Exponent* in the canonical-form representation of `Fraction`. 26.a

Ramification: If *Exponent* is less than `TMachine_Emin` and `Fraction` is nonzero, the result is either zero, `TModel_Small`, or (if `TDenorm` is `True`) a denormalized number. 26.b

`S'Scaling` `S'Scaling` denotes a function with the following specification: 27

```
function S'Scaling (X : T;
                   Adjustment : universal_integer)
return T
```

28

Let v be the value $X \cdot T\text{Machine_Radix}^{\text{Adjustment}}$. If v is a machine number of the type T , or if $|v| \geq T\text{Model_Small}$, the function yields v ; otherwise, it yields either one of the machine numbers of the type T adjacent to v . `Constraint_Error` is optionally raised if v is outside the base range of S . A zero result has the sign of X when `S'Signed_Zeros` is `True`. 29

Discussion: Informally, when X and v are both normalized numbers, the result is the value obtained by increasing the *exponent* by *Adjustment* in the canonical-form representation of X . 29.a

Ramification: If *Adjustment* is sufficiently small (i.e., sufficiently negative), the result is either zero, `TModel_Small`, or (if `TDenorm` is `True`) a denormalized number. 29.b

`S'Floor` `S'Floor` denotes a function with the following specification: 30

```
function S'Floor (X : T)
return T
```

31

The function yields the value $\lfloor X \rfloor$, i.e., the largest (most positive) integral value less than or equal to X . When X is zero, the result has the sign of X ; a zero result otherwise has a positive sign. 32

`S'Ceiling` `S'Ceiling` denotes a function with the following specification: 33

```
function S'Ceiling (X : T)
return T
```

34

The function yields the value $\lceil X \rceil$, i.e., the smallest (most negative) integral value greater than or equal to X . When X is zero, the result has the sign of X ; a zero result otherwise has a negative sign when `S'Signed_Zeros` is `True`. 35

`S'Rounding` `S'Rounding` denotes a function with the following specification: 36

```
function S'Rounding (X : T)
return T
```

37

The function yields the integral value nearest to X , rounding away from zero if X lies exactly halfway between two integers. A zero result has the sign of X when `S'Signed_Zeros` is `True`. 38

`S'Unbiased_Rounding` 39

`S'Unbiased_Rounding` denotes a function with the following specification:

```
function S'Unbiased_Rounding (X : T)
return T
```

40

The function yields the integral value nearest to X , rounding toward the even integer if X lies exactly halfway between two integers. A zero result has the sign of X when `S'Signed_Zeros` is `True`. 41

`S'Machine_Rounding` 41.1/2

{*AI95-00267-01*} `S'Machine_Rounding` denotes a function with the following specification:

```
function S'Machine_Rounding (X : T)
return T
```

41.2/2

The function yields the integral value nearest to X . If X lies exactly halfway between two integers, one of those integers is returned, but which of them is returned is unspecified. A 41.3/2

zero result has the sign of X when `S'Signed_Zeros` is `True`. This function provides access to the rounding behavior which is most efficient on the target processor.

41.a.1/2 **Discussion:** We leave the rounding unspecified, so that users cannot depend on a particular rounding. This attribute is intended for use in cases where the particular rounding chosen is irrelevant. If there is a need to know which way values halfway between two integers are rounded, one of the other rounding attributes should be used.

42 S'Truncation

S'Truncation denotes a function with the following specification:

```
43     function S'Truncation (X : T)
44         return T
```

44 The function yields the value $\lceil X \rceil$ when X is negative, and $\lfloor X \rfloor$ otherwise. A zero result has the sign of X when `S'Signed_Zeros` is `True`.

45 S'Remainder

S'Remainder denotes a function with the following specification:

```
46     function S'Remainder (X, Y : T)
47         return T
```

47 For nonzero Y , let v be the value $X - n \cdot Y$, where n is the integer nearest to the exact value of X/Y ; if $|n - X/Y| = 1/2$, then n is chosen to be even. If v is a machine number of the type T , the function yields v ; otherwise, it yields zero. `Constraint_Error` is raised if Y is zero. A zero result has the sign of X when `S'Signed_Zeros` is `True`.

47.a **Ramification:** The magnitude of the result is less than or equal to one-half the magnitude of Y .

47.b **Discussion:** Given machine numbers X and Y of the type T , v is necessarily a machine number of the type T , except when Y is in the neighborhood of zero, X is sufficiently close to a multiple of Y , and `T'Denorm` is `False`.

48 S'Adjacent S'Adjacent denotes a function with the following specification:

```
49     function S'Adjacent (X, Towards : T)
50         return T
```

50 If `Towards = X`, the function yields X ; otherwise, it yields the machine number of the type T adjacent to X in the direction of `Towards`, if that machine number exists. If the result would be outside the base range of `S`, `Constraint_Error` is raised. When `T'Signed_Zeros` is `True`, a zero result has the sign of X . When `Towards` is zero, its sign has no bearing on the result.

50.a **Ramification:** The value of `S'Adjacent(0.0, 1.0)` is the smallest normalized positive number of the type T when `T'Denorm` is `False` and the smallest denormalized positive number of the type T when `T'Denorm` is `True`.

51 S'Copy_Sign

S'Copy_Sign denotes a function with the following specification:

```
52     function S'Copy_Sign (Value, Sign : T)
53         return T
```

53 If the value of `Value` is nonzero, the function yields a result whose magnitude is that of `Value` and whose sign is that of `Sign`; otherwise, it yields the value zero. `Constraint_Error` is optionally raised if the result is outside the base range of `S`. A zero result has the sign of `Sign` when `S'Signed_Zeros` is `True`.

53.a **Discussion:** `S'Copy_Sign` is provided for convenience in restoring the sign to a quantity from which it has been temporarily removed, or to a related quantity. When `S'Signed_Zeros` is `True`, it is also instrumental in determining the sign of a zero quantity, when required. (Because negative and positive zeros compare equal in systems conforming to IEC 559:1989, a negative zero does *not* appear to be negative when compared to zero.) The sign determination is accomplished by transferring the sign of the zero quantity to a nonzero quantity and then testing for a negative result.

54 S'Leading_Part

S'Leading_Part denotes a function with the following specification:

```
55     function S'Leading_Part (X : T;
56                           Radix_Digits : universal_integer)
57         return T
```

Let v be the value $TMachine_Radix^{k-Radix_Digits}$, where k is the normalized exponent of X . The function yields the value 56

- $\lfloor X/v \rfloor \cdot v$, when X is nonnegative and $Radix_Digits$ is positive; 57
- $\lceil X/v \rceil \cdot v$, when X is negative and $Radix_Digits$ is positive. 58

Constraint_Error is raised when $Radix_Digits$ is zero or negative. A zero result[, which can only occur when X is zero,] has the sign of X . 59

Discussion: Informally, if X is nonzero, the result is the value obtained by retaining only the specified number of (leading) significant digits of X (in the machine radix), setting all other digits to zero. 59.a

Implementation Note: The result can be obtained by first scaling X up, if necessary to normalize it, then masking the mantissa so as to retain only the specified number of leading digits, then scaling the result back down if X was scaled up. 59.b

S'Machine S'Machine denotes a function with the following specification: 60

```
function S'Machine (X : T)
return T 61
```

If X is a machine number of the type T , the function yields X ; otherwise, it yields the value obtained by rounding or truncating X to either one of the adjacent machine numbers of the type T . Constraint_Error is raised if rounding or truncating X to the precision of the machine numbers results in a value outside the base range of S. A zero result has the sign of X when S'Signed_Zeros is True. 62

Discussion: {A105-0005-1} All of the primitive function attributes except Rounding and Machine correspond to subprograms in the Generic_Primitive_Functions generic package that was proposed as a separate ISO standard (ISO/IEC DIS 11729) for Ada 83. The Scaling, Unbiased_Rounding, and Truncation attributes correspond to the Scale, Round, and Truncate functions, respectively, in Generic_Primitive_Functions. The Rounding attribute rounds away from zero; this functionality was not provided in Generic_Primitive_Functions. The name Round was not available for either of the primitive function attributes that perform rounding, since an attribute of that name is used for a different purpose for decimal fixed point types. Likewise, the name Scale was not available, since an attribute of that name is also used for a different purpose for decimal fixed point types. The functionality of the Machine attribute was also not provided in Generic_Primitive_Functions. The functionality of the Decompose procedure of Generic_Primitive_Functions is only provided in the form of the separate attributes Exponent and Fraction. The functionality of the Successor and Predecessor functions of Generic_Primitive_Functions is provided by the extension of the existing Succ and Pred attributes. 62.a/3

Implementation Note: The primitive function attributes may be implemented either with appropriate floating point arithmetic operations or with integer and logical operations that act on parts of the representation directly. The latter is strongly encouraged when it is more efficient than the former; it is mandatory when the former cannot deliver the required accuracy due to limitations of the implementation's arithmetic operations. 62.b

The following *model-oriented attributes* are defined for any subtype S of a floating point type T. 63

S'Model_Mantissa 64

If the Numerics Annex is not supported, this attribute yields an implementation defined value that is greater than or equal to $\lfloor d \cdot \log(10) / \log(TMachine_Radix) \rfloor + 1$, where d is the requested decimal precision of T , and less than or equal to the value of T'Machine_Mantissa. See G.2.2 for further requirements that apply to implementations supporting the Numerics Annex. The value of this attribute is of the type *universal_integer*.

S'Model_Emin 65

If the Numerics Annex is not supported, this attribute yields an implementation defined value that is greater than or equal to the value of T'Machine_Emin. See G.2.2 for further requirements that apply to implementations supporting the Numerics Annex. The value of this attribute is of the type *universal_integer*.

S'Model_Epsilon 66

Yields the value $TMachine_Radix^{1 - T'Model_Mantissa}$. The value of this attribute is of the type *universal_real*.

66.a **Discussion:** In most implementations, this attribute yields the absolute value of the difference between one and the smallest machine number of the type T above one which, when added to one, yields a machine number different from one. Further discussion can be found in G.2.2.

67 **S'Model_Small**
 Yields the value $T\text{Machine_Radix}^{T\text{Model_Emin} - 1}$. The value of this attribute is of the type *universal_real*.

67.a **Discussion:** In most implementations, this attribute yields the smallest positive normalized number of the type T , i.e. the number corresponding to the positive underflow threshold. In some implementations employing a radix-complement representation for the type T , the positive underflow threshold is closer to zero than is the negative underflow threshold, with the consequence that the smallest positive normalized number does not coincide with the positive underflow threshold (i.e., it exceeds the latter). Further discussion can be found in G.2.2.

68 **S'Model** S'Model denotes a function with the following specification:

```
69      function S'Model (X : T)
      return T
```

70 If the Numerics Annex is not supported, the meaning of this attribute is implementation defined; see G.2.2 for the definition that applies to implementations supporting the Numerics Annex.

71 **S'Safe_First**
 Yields the lower bound of the safe range (see 3.5.7) of the type T . If the Numerics Annex is not supported, the value of this attribute is implementation defined; see G.2.2 for the definition that applies to implementations supporting the Numerics Annex. The value of this attribute is of the type *universal_real*.

72 **S'Safe_Last**
 Yields the upper bound of the safe range (see 3.5.7) of the type T . If the Numerics Annex is not supported, the value of this attribute is implementation defined; see G.2.2 for the definition that applies to implementations supporting the Numerics Annex. The value of this attribute is of the type *universal_real*.

72.a **Discussion:** A predefined floating point arithmetic operation that yields a value in the safe range of its result type is guaranteed not to overflow.

72.b **To be honest:** An exception is made for exponentiation by a negative exponent in 4.5.6.

72.c **Implementation defined:** The values of the Model_Mantissa, Model_Emin, Model_Epsilon, Model, Safe_First, and Safe_Last attributes, if the Numerics Annex is not supported.

Incompatibilities With Ada 83

72.d The Epsilon and Mantissa attributes of floating point types are removed from the language and replaced by Model_Epsilon and Model_Mantissa, which may have different values (as a result of changes in the definition of model numbers); the replacement of one set of attributes by another is intended to convert what would be an inconsistent change into an incompatible change.

72.e The Emax, Small, Large, Safe_Emax, Safe_Small, and Safe_Large attributes of floating point types are removed from the language. Small and Safe_Small are collectively replaced by Model_Small, which is functionally equivalent to Safe_Small, though it may have a slightly different value. The others are collectively replaced by Safe_First and Safe_Last. Safe_Last is functionally equivalent to Safe_Large, though it may have a different value; Safe_First is comparable to the negation of Safe_Large but may differ slightly from it as well as from the negation of Safe_Last. Emax and Safe_Emax had relatively few uses in Ada 83; T'Safe_Emax can be computed in the revised language as Integer'Min(T'Exponent(T'Safe_First), T'Exponent(T'Safe_Last)).

72.f Implementations are encouraged to eliminate the incompatibilities discussed here by retaining the old attributes, during a transition period, in the form of implementation-defined attributes with their former values.

Extensions to Ada 83

72.g The Model_Emin attribute is new. It is conceptually similar to the negation of Safe_Emax attribute of Ada 83, adjusted for the fact that the model numbers now have the hardware radix. It is a fundamental determinant, along with Model_Mantissa, of the set of model numbers of a type (see G.2.1).

72.h The Denorm and Signed_Zeros attributes are new, as are all of the primitive function attributes.

Extensions to Ada 95

{AI95-00388-01} The Machine_Rounding attribute is new.

72.ii/2

A.5.4 Attributes of Fixed Point Types

Static Semantics

The following *representation-oriented* attributes are defined for every subtype S of a fixed point type T. 1

S'Machine_Radix 2

Yields the radix of the hardware representation of the type T. The value of this attribute is of the type *universal_integer*.

S'Machine_Rounds 3

Yields the value True if rounding is performed on inexact results of every predefined operation that yields a result of the type T; yields the value False otherwise. The value of this attribute is of the predefined type Boolean.

S'Machine_Overflows 4

Yields the value True if overflow and divide-by-zero are detected and reported by raising Constraint_Error for every predefined operation that yields a result of the type T; yields the value False otherwise. The value of this attribute is of the predefined type Boolean.

Incompatibilities With Ada 83

The Mantissa, Large, Safe_Small, and Safe_Large attributes of fixed point types are removed from the language. 4.a

Implementations are encouraged to eliminate the resulting incompatibility by retaining these attributes, during a transition period, in the form of implementation-defined attributes with their former values. 4.b

Extensions to Ada 83

The Machine_Radix attribute is now allowed for fixed point types. It is also specifiable in an attribute definition clause (see F.1). 4.c

A.6 Input-Output

{AI95-00285-01} [Input-output is provided through language-defined packages, each of which is a child of the root package Ada. The generic packages Sequential_IO and Direct_IO define input-output operations applicable to files containing elements of a given type. The generic package Storage_IO supports reading from and writing to an in-memory buffer. Additional operations for text input-output are supplied in the packages Text_IO, Wide_Text_IO, and Wide_Wide_Text_IO. Heterogeneous input-output is provided through the child packages Streams.Stream_IO and Text_IO.Text_Streams (see also 13.13). The package IO_Exceptions defines the exceptions needed by the predefined input-output packages.] 1/2

Inconsistencies With Ada 83

The introduction of Append_File as a new element of the enumeration type File_Mode in Sequential_IO and Text_IO, and the introduction of several new declarations in Text_IO, may result in name clashes in the presence of **use** clauses. 1.a

Extensions to Ada 83

Text_IO enhancements (Get_Immediate, Look_Ahead, Standard_Error, Modular_IO, Decimal_IO), Wide_Text_IO, and the stream input-output facilities are new in Ada 95. 1.b

Wording Changes from Ada 83

RM83-14.6, "Low Level Input-Output," is removed. This has no semantic effect, since the package was entirely implementation defined, nobody actually implemented it, and if they did, they can always provide it as a vendor-supplied package. 1.c

1.d/2 {AI95-00285-01} Included package Wide_Wide_Text_IO in this description.

A.7 External Files and File Objects

Static Semantics

- 1 Values input from the external environment of the program, or output to the external environment, are considered to occupy *external files*. An external file can be anything external to the program that can produce a value to be read or receive a value to be written. An external file is identified by a string (the *name*). A second string (the *form*) gives further system-dependent characteristics that may be associated with the file, such as the physical organization or access rights. The conventions governing the interpretation of such strings shall be documented.
- 2/3 {AI05-0299-1} Input and output operations are expressed as operations on objects of some *file type*, rather than directly in terms of the external files. In the remainder of this clause, the term *file* is always used to refer to a file object; the term *external file* is used otherwise.
- 3 Input-output for sequential files of values of a single element type is defined by means of the generic package Sequential_IO. In order to define sequential input-output for a given element type, an instantiation of this generic unit, with the given type as actual parameter, has to be declared. The resulting package contains the declaration of a file type (called File_Type) for files of such elements, as well as the operations applicable to these files, such as the Open, Read, and Write procedures.
- 4/2 {AI95-00285-01} Input-output for direct access files is likewise defined by a generic package called Direct_IO. Input-output in human-readable form is defined by the (nongeneric) packages Text_IO for Character and String data, Wide_Text_IO for Wide_Character and Wide_String data, and Wide_Wide_Text_IO for Wide_Wide_Character and Wide_Wide_String data. Input-output for files containing streams of elements representing values of possibly different types is defined by means of the (nongeneric) package Streams.Stream_IO.
- 5 Before input or output operations can be performed on a file, the file first has to be associated with an external file. While such an association is in effect, the file is said to be *open*, and otherwise the file is said to be *closed*.
- 6 The language does not define what happens to external files after the completion of the main program and all the library tasks (in particular, if corresponding files have not been closed). The effect of input-output for access types is unspecified.
- 7 An open file has a *current mode*, which is a value of one of the following enumeration types:
- 8 `type File_Mode is (In_File, Inout_File, Out_File); -- for Direct_IO`
- 9 These values correspond respectively to the cases where only reading, both reading and writing, or only writing are to be performed.
- 10/2 {AI95-00285-01} `type File_Mode is (In_File, Out_File, Append_File);`
`-- for Sequential_IO, Text_IO, Wide_Text_IO, Wide_Wide_Text_IO, and Stream_IO`
- 11 These values correspond respectively to the cases where only reading, only writing, or only appending are to be performed.
- 12 The mode of a file can be changed.
- 13/2 {AI95-00285-01} Several file management operations are common to Sequential_IO, Direct_IO, Text_IO, Wide_Text_IO, and Wide_Wide_Text_IO. These operations are described in subclause A.8.2

for sequential and direct files. Any additional effects concerning text input-output are described in subclause A.10.2.

{AI05-0299-1} The exceptions that can be propagated by the execution of an input-output subprogram are defined in the package `IO_Exceptions`; the situations in which they can be propagated are described following the description of the subprogram (and in subclause A.13). The exceptions `Storage_Error` and `Program_Error` may be propagated. (`Program_Error` can only be propagated due to errors made by the caller of the subprogram.) Finally, exceptions can be propagated in certain implementation-defined situations. 14/3

This paragraph was deleted. 14.a/2

Discussion: The last sentence here is referring to the documentation requirements in A.13, “Exceptions in Input-Output”, and the documentation summary item is provided there. 14.b/2

NOTES

23 {AI95-00285-01} Each instantiation of the generic packages `Sequential_IO` and `Direct_IO` declares a different type `File_Type`. In the case of `Text_IO`, `Wide_Text_IO`, `Wide_Wide_Text_IO`, and `Streams.Stream_IO`, the corresponding type `File_Type` is unique. 15/2

24 A bidirectional device can often be modeled as two sequential files associated with the device, one of mode `In_File`, and one of mode `Out_File`. An implementation may restrict the number of files that may be associated with a given external file. 16

Wording Changes from Ada 95

{AI95-00285-01} Included package `Wide_Wide_Text_IO` in this description. 16.a/2

A.8 Sequential and Direct Files

Static Semantics

{AI95-00283-01} Two kinds of access to external files are defined in this subclause: *sequential access* and *direct access*. The corresponding file types and the associated operations are provided by the generic packages `Sequential_IO` and `Direct_IO`. A file object to be used for sequential access is called a *sequential file*, and one to be used for direct access is called a *direct file*. Access to *stream files* is described in A.12.1. 1/2

For sequential access, the file is viewed as a sequence of values that are transferred in the order of their appearance (as produced by the program or by the external environment). When the file is opened with mode `In_File` or `Out_File`, transfer starts respectively from or to the beginning of the file. When the file is opened with mode `Append_File`, transfer to the file starts after the last element of the file. 2

Discussion: Adding stream I/O necessitates a review of the terminology. In Ada 83, ‘sequential’ implies both the access method (purely sequential — that is, no indexing or positional access) and homogeneity. Direct access includes purely sequential access and indexed access, as well as homogeneity. In Ada 95, streams allow purely sequential access but also positional access to an individual element, and are heterogeneous. We considered generalizing the notion of ‘sequential file’ to include both `Sequential_IO` and `Stream_IO` files, but since streams allow positional access it seems misleading to call them sequential files. Or, looked at differently, if the criterion for calling something a sequential file is whether it permits (versus requires) purely sequential access, then one could just as soon regard a `Direct_IO` file as a sequential file. 2.a

It seems better to regard ‘sequential file’ as meaning ‘only permitting purely sequential access’; hence we have decided to supplement ‘sequential access’ and ‘direct access’ with a third category, informally called ‘access to streams’. (We decided against the term ‘stream access’ because of possible confusion with the `Stream_Access` type declared in one of the stream packages.) 2.b

For direct access, the file is viewed as a set of elements occupying consecutive positions in linear order; a value can be transferred to or from an element of the file at any selected position. The position of an element is specified by its *index*, which is a number, greater than zero, of the implementation-defined integer type `Count`. The first element, if any, has index one; the index of the last element, if any, is called 3

the *current size*; the current size is zero if there are no elements. The current size is a property of the external file.

- 4 An open direct file has a *current index*, which is the index that will be used by the next read or write operation. When a direct file is opened, the current index is set to one. The current index of a direct file is a property of a file object, not of an external file.

Wording Changes from Ada 95

4.a/2 {AI95-00283-01} Italicized “stream file” to clarify that this is another kind of file.

A.8.1 The Generic Package Sequential_IO

Static Semantics

1 The generic library package Sequential_IO has the following declaration:

```

2  with Ada.IO_Exceptions;
   generic
     type Element_Type(<>) is private;
   package Ada.Sequential_IO is
3     type File_Type is limited private;
4     type File_Mode is (In_File, Out_File, Append_File);
5     -- File management
6     procedure Create(File : in out File_Type;
                      Mode : in File_Mode := Out_File;
                      Name : in String := "";
                      Form : in String := "");
7     procedure Open (File : in out File_Type;
                    Mode : in File_Mode;
                    Name : in String;
                    Form : in String := "");
8     procedure Close (File : in out File_Type);
     procedure Delete(File : in out File_Type);
     procedure Reset (File : in out File_Type; Mode : in File_Mode);
     procedure Reset (File : in out File_Type);
9     function Mode (File : in File_Type) return File_Mode;
     function Name (File : in File_Type) return String;
     function Form (File : in File_Type) return String;
10    function Is_Open(File : in File_Type) return Boolean;
11    -- Input and output operations
12    procedure Read (File : in File_Type; Item : out Element_Type);
     procedure Write (File : in File_Type; Item : in Element_Type);
13    function End_Of_File(File : in File_Type) return Boolean;
14    -- Exceptions
15    Status_Error : exception renames IO_Exceptions.Status_Error;
     Mode_Error : exception renames IO_Exceptions.Mode_Error;
     Name_Error : exception renames IO_Exceptions.Name_Error;
     Use_Error : exception renames IO_Exceptions.Use_Error;
     Device_Error : exception renames IO_Exceptions.Device_Error;
     End_Error : exception renames IO_Exceptions.End_Error;
     Data_Error : exception renames IO_Exceptions.Data_Error;
16    private
     ... -- not specified by the language
   end Ada.Sequential_IO;
```

17/2 {AI95-00360-01} The type File_Type needs finalization (see 7.6) in every instantiation of Sequential_IO.

Incompatibilities With Ada 83

The new enumeration element `Append_File` may introduce upward incompatibilities. It is possible that a program based on the assumption that `File_Mode'Last = Out_File` will be illegal (e.g., case statement choice coverage) or execute with a different effect in Ada 95. 17.a

This paragraph was deleted. {8652/0097} {AI95-00115-01} {AI95-00344-01} 17.a.1/2

Incompatibilities With Ada 95

{AI95-00360-01} **Amendment Correction:** `File_Type` in an instance of `Sequential_IO` is defined to need finalization. If the restriction `No_Nested_Finalization` (see D.7) applies to the partition, and `File_Type` does not have a controlled part, it will not be allowed in local objects in Ada 2005 whereas it would be allowed in original Ada 95. Such code is not portable, as another Ada compiler may have a controlled part in `File_Type`, and thus would be illegal. 17.b/2

A.8.2 File Management

Static Semantics

The procedures and functions described in this subclause provide for the control of external files; their declarations are repeated in each of the packages for sequential, direct, text, and stream input-output. For text input-output, the procedures `Create`, `Open`, and `Reset` have additional effects described in subclause A.10.2. 1

```
procedure Create(File : in out File_Type;  
                Mode : in File_Mode := default_mode;  
                Name : in String := "";  
                Form : in String := ""); 2
```

{AI95-00283-01} Establishes a new external file, with the given name and form, and associates this external file with the given file. The given file is left open. The current mode of the given file is set to the given access mode. The default access mode is the mode `Out_File` for sequential, stream, and text input-output; it is the mode `Inout_File` for direct input-output. For direct access, the size of the created file is implementation defined. 3/2

A null string for `Name` specifies an external file that is not accessible after the completion of the main program (a temporary file). A null string for `Form` specifies the use of the default options of the implementation for the external file. 4

The exception `Status_Error` is propagated if the given file is already open. The exception `Name_Error` is propagated if the string given as `Name` does not allow the identification of an external file. The exception `Use_Error` is propagated if, for the specified mode, the external environment does not support creation of an external file with the given name (in the absence of `Name_Error`) and form. 5

```
procedure Open(File : in out File_Type;  
              Mode : in File_Mode;  
              Name : in String;  
              Form : in String := ""); 6
```

Associates the given file with an existing external file having the given name and form, and sets the current mode of the given file to the given mode. The given file is left open. 7

The exception `Status_Error` is propagated if the given file is already open. The exception `Name_Error` is propagated if the string given as `Name` does not allow the identification of an external file; in particular, this exception is propagated if no external file with the given name exists. The exception `Use_Error` is propagated if, for the specified mode, the external environment does not support opening for an external file with the given name (in the absence of `Name_Error`) and form. 8

9 **procedure** Close(File : in out File_Type);

10 Severs the association between the given file and its associated external file. The given file is left closed. In addition, for sequential files, if the file being closed has mode Out_File or Append_File, then the last element written since the most recent open or reset is the last element that can be read from the file. If no elements have been written and the file mode is Out_File, then the closed file is empty. If no elements have been written and the file mode is Append_File, then the closed file is unchanged.

11 The exception Status_Error is propagated if the given file is not open.

12 **procedure** Delete(File : in out File_Type);

13 Deletes the external file associated with the given file. The given file is closed, and the external file ceases to exist.

14 The exception Status_Error is propagated if the given file is not open. The exception Use_Error is propagated if deletion of the external file is not supported by the external environment.

15 **procedure** Reset(File : in out File_Type; Mode : in File_Mode);

procedure Reset(File : in out File_Type);

16/2 {AI95-00085-01} Resets the given file so that reading from its elements can be restarted from the beginning of the external file (for modes In_File and Inout_File), and so that writing to its elements can be restarted at the beginning of the external file (for modes Out_File and Inout_File) or after the last element of the external file (for mode Append_File). In particular, for direct access this means that the current index is set to one. If a Mode parameter is supplied, the current mode of the given file is set to the given mode. In addition, for sequential files, if the given file has mode Out_File or Append_File when Reset is called, the last element written since the most recent open or reset is the last element that can be read from the external file. If no elements have been written and the file mode is Out_File, the reset file is empty. If no elements have been written and the file mode is Append_File, then the reset file is unchanged.

17 The exception Status_Error is propagated if the file is not open. The exception Use_Error is propagated if the external environment does not support resetting for the external file and, also, if the external environment does not support resetting to the specified mode for the external file.

18 **function** Mode(File : in File_Type) **return** File_Mode;

19 Returns the current mode of the given file.

20 The exception Status_Error is propagated if the file is not open.

21 **function** Name(File : in File_Type) **return** String;

22/2 {AI95-00248-01} Returns a string which uniquely identifies the external file currently associated with the given file (and may thus be used in an Open operation).

22.a/2 **Discussion:** {AI95-00248-01} Retrieving the full path can be accomplished by passing the result of Name to Directories.Full_Name (see A.16). It is important to drop the requirement on Name, as the only way to accomplish this requirement given that the current directory can be changed with package Directories is to store the full path when the file is opened. That's expensive, and it's better for users that need the full path to explicitly request it.

23 The exception Status_Error is propagated if the given file is not open. The exception Use_Error is propagated if the associated external file is a temporary file that cannot be opened by any name.

24 **function** Form(File : in File_Type) **return** String;

25 Returns the form string for the external file currently associated with the given file. If an external environment allows alternative specifications of the form (for example, abbreviations using

default options), the string returned by the function should correspond to a full specification (that is, it should indicate explicitly all options selected, including default options).

The exception `Status_Error` is propagated if the given file is not open. 26

```
function Is_Open(File : in File_Type) return Boolean; 27
```

{AI05-0264-1} Returns True if the file is open (that is, if it is associated with an external file); 28/3
otherwise, returns False.

Implementation Permissions

An implementation may propagate `Name_Error` or `Use_Error` if an attempt is made to use an I/O feature that cannot be supported by the implementation due to limitations in the external environment. Any such restriction should be documented. 29

Wording Changes from Ada 95

{AI95-00085-01} Clarified that `Reset` affects and depends on the external file. 29.a/2

{AI95-00248-01} Removed the requirement for `Name` to return a full path; this is now accomplished by `Directories.Full_Name(Name(File))` (see A.16). This is not documented as an inconsistency, because there is no requirement for implementations to change — the Ada 95 behavior is still allowed, it just is no longer required. 29.b/2

{AI95-00283-01} Added text to specify the default mode for a stream file. 29.c/2

A.8.3 Sequential Input-Output Operations

Static Semantics

The operations available for sequential input and output are described in this subclause. The exception `Status_Error` is propagated if any of these operations is attempted for a file that is not open. 1

```
procedure Read(File : in File_Type; Item : out Element_Type); 2
```

Operates on a file of mode `In_File`. Reads an element from the given file, and returns the value of this element in the `Item` parameter. 3

Discussion: We considered basing `Sequential_IO.Read` on `Element_Type'Read` from an implicit stream associated with the sequential file. However, `Element_Type'Read` is a type-related attribute, whereas `Sequential_IO` should take advantage of the particular constraints of the actual subtype corresponding to `Element_Type` to minimize the size of the external file. Furthermore, forcing the implementation of `Sequential_IO` to be based on `Element_Type'Read` would create an upward incompatibility since existing data files written by an Ada 83 program using `Sequential_IO` might not be readable by the identical program built with an Ada 95 implementation of `Sequential_IO`. 3.a

An Ada 95 implementation might still use an implementation-defined attribute analogous to `'Read` to implement the procedure `Read`, but that attribute will likely have to be subtype-specific rather than type-related, and it need not be user-specifiable. Such an attribute will presumably be needed to implement the generic package `Storage_IO` (see A.9). 3.b

The exception `Mode_Error` is propagated if the mode is not `In_File`. The exception `End_Error` is propagated if no more elements can be read from the given file. The exception `Data_Error` can be propagated if the element read cannot be interpreted as a value of the subtype `Element_Type` (see A.13, “Exceptions in Input-Output”). 4

Discussion: `Data_Error` need not be propagated if the check is too complex. See A.13, “Exceptions in Input-Output”. 4.a

```
procedure Write(File : in File_Type; Item : in Element_Type); 5
```

Operates on a file of mode `Out_File` or `Append_File`. Writes the value of `Item` to the given file. 6

The exception `Mode_Error` is propagated if the mode is not `Out_File` or `Append_File`. The exception `Use_Error` is propagated if the capacity of the external file is exceeded. 7

8 **function** End_Of_File(File : **in** File_Type) **return** Boolean;
 9/3 {AI05-0264-1} Operates on a file of mode In_File. Returns True if no more elements can be read
 from the given file; otherwise, returns False.
 10 The exception Mode_Error is propagated if the mode is not In_File.

A.8.4 The Generic Package Direct_IO

Static Semantics

1 The generic library package Direct_IO has the following declaration:
 2 **with** Ada.IO_Exceptions;
 generic
 type Element_Type **is private**;
 package Ada.Direct_IO **is**
 3 **type** File_Type **is limited private**;
 4 **type** File_Mode **is** (In_File, Inout_File, Out_File);
 type Count **is range** 0 .. *implementation-defined*;
 subtype Positive_Count **is** Count **range** 1 .. Count'Last;
 5 -- File management
 6 **procedure** Create(File : **in out** File_Type;
 Mode : **in** File_Mode := Inout_File;
 Name : **in** String := "";
 Form : **in** String := "");
 7 **procedure** Open (File : **in out** File_Type;
 Mode : **in** File_Mode;
 Name : **in** String;
 Form : **in** String := "");
 8 **procedure** Close (File : **in out** File_Type);
 procedure Delete(File : **in out** File_Type);
 procedure Reset (File : **in out** File_Type; Mode : **in** File_Mode);
 procedure Reset (File : **in out** File_Type);
 9 **function** Mode (File : **in** File_Type) **return** File_Mode;
 function Name (File : **in** File_Type) **return** String;
 function Form (File : **in** File_Type) **return** String;
 10 **function** Is_Open(File : **in** File_Type) **return** Boolean;
 11 -- Input and output operations
 12 **procedure** Read (File : **in** File_Type; Item : **out** Element_Type;
 From : **in** Positive_Count);
 procedure Read (File : **in** File_Type; Item : **out** Element_Type);
 13 **procedure** Write(File : **in** File_Type; Item : **in** Element_Type;
 To : **in** Positive_Count);
 procedure Write(File : **in** File_Type; Item : **in** Element_Type);
 14 **procedure** Set_Index(File : **in** File_Type; To : **in** Positive_Count);
 15 **function** Index(File : **in** File_Type) **return** Positive_Count;
 function Size (File : **in** File_Type) **return** Count;
 16 **function** End_Of_File(File : **in** File_Type) **return** Boolean;
 17 -- Exceptions
 18 Status_Error : **exception renames** IO_Exceptions.Status_Error;
 Mode_Error : **exception renames** IO_Exceptions.Mode_Error;
 Name_Error : **exception renames** IO_Exceptions.Name_Error;
 Use_Error : **exception renames** IO_Exceptions.Use_Error;
 Device_Error : **exception renames** IO_Exceptions.Device_Error;
 End_Error : **exception renames** IO_Exceptions.End_Error;
 Data_Error : **exception renames** IO_Exceptions.Data_Error;

12 **function** Size(File : **in** File_Type) **return** Count;

13 Operates on a file of any mode. Returns the current size of the external file that is associated with the given file.

14 **function** End_Of_File(File : **in** File_Type) **return** Boolean;

15/3 {AI05-0264-1} Operates on a file of mode In_File or Inout_File. Returns True if the current index exceeds the size of the external file; otherwise, returns False.

16 The exception Mode_Error is propagated if the mode of the given file is Out_File.

NOTES

17 25 Append_File mode is not supported for the generic package Direct_IO.

A.9 The Generic Package Storage_IO

1 The generic package Storage_IO provides for reading from and writing to an in-memory buffer. This generic package supports the construction of user-defined input-output packages.

1.a **Reason:** This package exists to allow the portable construction of user-defined direct-access-oriented input-output packages. The Write procedure writes a value of type Element_Type into a Storage_Array of size Buffer_Size, flattening out any implicit levels of indirection used in the representation of the type. The Read procedure reads a value of type Element_Type from the buffer, reconstructing any implicit levels of indirection used in the representation of the type. It also properly initializes any type tags that appear within the value, presuming that the buffer was written by a different program and that tag values for the “same” type might vary from one executable to another.

Static Semantics

2 The generic library package Storage_IO has the following declaration:

```

3     with Ada.IO_Exceptions;
4     with System.Storage_Elements;
5     generic
6         type Element_Type is private;
7     package Ada.Storage_IO is
8         pragma Preelaborate(Storage_IO);
9         Buffer_Size : constant System.Storage_Elements.Storage_Count :=
10             implementation-defined;
11         subtype Buffer_Type is
12             System.Storage_Elements.Storage_Array(1..Buffer_Size);
13         -- Input and output operations
14         procedure Read (Buffer : in Buffer_Type; Item : out Element_Type);
15         procedure Write(Buffer : out Buffer_Type; Item : in Element_Type);
16         -- Exceptions
17         Data_Error : exception renames IO_Exceptions.Data_Error;
18     end Ada.Storage_IO;
```

10 In each instance, the constant Buffer_Size has a value that is the size (in storage elements) of the buffer required to represent the content of an object of subtype Element_Type, including any implicit levels of indirection used by the implementation. The Read and Write procedures of Storage_IO correspond to the Read and Write procedures of Direct_IO (see A.8.4), but with the content of the Item parameter being read from or written into the specified Buffer, rather than an external file.

10.a **Reason:** As with Direct_IO, the Element_Type formal of Storage_IO does not have an unknown_discriminant_part so that there is a well-defined upper bound on the size of the buffer needed to hold the content of an object of the formal subtype (i.e. Buffer_Size). If there are no implicit levels of indirection, Buffer_Size will typically equal:

10.b (Element_Type'Size + System.Storage_Unit - 1) / System.Storage_Unit

10.c **Implementation defined:** The value of Buffer_Size in Storage_IO.

NOTES

26 A buffer used for Storage_IO holds only one element at a time; an external file used for Direct_IO holds a sequence of elements. 11

Extensions to Ada 83

{AI05-0005-1} Storage_IO is new in Ada 95. 11.a/3

A.10 Text Input-Output*Static Semantics*

{AI05-0299-1} This subclause describes the package Text_IO, which provides facilities for input and output in human-readable form. Each file is read or written sequentially, as a sequence of characters grouped into lines, and as a sequence of lines grouped into pages. The specification of the package is given below in subclause A.10.1. 1/3

{AI05-0299-1} The facilities for file management given above, in subclauses A.8.2 and A.8.3, are available for text input-output. In place of Read and Write, however, there are procedures Get and Put that input values of suitable types from text files, and output values to them. These values are provided to the Put procedures, and returned by the Get procedures, in a parameter Item. Several overloaded procedures of these names exist, for different types of Item. These Get procedures analyze the input sequences of characters based on lexical elements (see Clause 2) and return the corresponding values; the Put procedures output the given values as appropriate lexical elements. Procedures Get and Put are also available that input and output individual characters treated as character values rather than as lexical elements. Related to character input are procedures to look ahead at the next character without reading it, and to read a character “immediately” without waiting for an end-of-line to signal availability. 2/3

In addition to the procedures Get and Put for numeric and enumeration types of Item that operate on text files, analogous procedures are provided that read from and write to a parameter of type String. These procedures perform the same analysis and composition of character sequences as their counterparts which have a file parameter. 3

For all Get and Put procedures that operate on text files, and for many other subprograms, there are forms with and without a file parameter. Each such Get procedure operates on an input file, and each such Put procedure operates on an output file. If no file is specified, a default input file or a default output file is used. 4

At the beginning of program execution the default input and output files are the so-called standard input file and standard output file. These files are open, have respectively the current modes In_File and Out_File, and are associated with two implementation-defined external files. Procedures are provided to change the current default input file and the current default output file. 5

Implementation defined: The external files associated with the standard input, standard output, and standard error files. 5.a/2

Implementation Note: {8652/0113} {AI95-00087-01} The default input file and default output file are not the names of distinct file objects, but rather the *role* played by one or more (other) file object(s). Thus, they generally will be implemented as accesses to another file object. An implementation that implements them by copying them is incorrect. 5.a.1/1

At the beginning of program execution a default file for program-dependent error-related text output is the so-called standard error file. This file is open, has the current mode Out_File, and is associated with an implementation-defined external file. A procedure is provided to change the current default error file. 6

From a logical point of view, a text file is a sequence of pages, a page is a sequence of lines, and a line is a sequence of characters; the end of a line is marked by a *line terminator*; the end of a page is marked by the combination of a line terminator immediately followed by a *page terminator*; and the end of a file is 7

marked by the combination of a line terminator immediately followed by a page terminator and then a *file terminator*. Terminators are generated during output; either by calls of procedures provided expressly for that purpose; or implicitly as part of other operations, for example, when a bounded line length, a bounded page length, or both, have been specified for a file.

- 8 The actual nature of terminators is not defined by the language and hence depends on the implementation. Although terminators are recognized or generated by certain of the procedures that follow, they are not necessarily implemented as characters or as sequences of characters. Whether they are characters (and if so which ones) in any particular implementation need not concern a user who neither explicitly outputs nor explicitly inputs control characters. The effect of input (Get) or output (Put) of control characters (other than horizontal tabulation) is not specified by the language.
- 9 The characters of a line are numbered, starting from one; the number of a character is called its *column number*. For a line terminator, a column number is also defined: it is one more than the number of characters in the line. The lines of a page, and the pages of a file, are similarly numbered. The current column number is the column number of the next character or line terminator to be transferred. The current line number is the number of the current line. The current page number is the number of the current page. These numbers are values of the subtype `Positive_Count` of the type `Count` (by convention, the value zero of the type `Count` is used to indicate special conditions).

```
10     type Count is range 0 .. implementation-defined;
      subtype Positive_Count is Count range 1 .. Count'Last;
```

- 11 For an output file or an append file, a *maximum line length* can be specified and a *maximum page length* can be specified. If a value to be output cannot fit on the current line, for a specified maximum line length, then a new line is automatically started before the value is output; if, further, this new line cannot fit on the current page, for a specified maximum page length, then a new page is automatically started before the value is output. Functions are provided to determine the maximum line length and the maximum page length. When a file is opened with mode `Out_File` or `Append_File`, both values are zero: by convention, this means that the line lengths and page lengths are unbounded. (Consequently, output consists of a single line if the subprograms for explicit control of line and page structure are not used.) The constant `Unbounded` is provided for this purpose.

Extensions to Ada 83

- 11.a `Append_File` is new in Ada 95.

A.10.1 The Package `Text_IO`

Static Semantics

- 1 The library package `Text_IO` has the following declaration:
- ```
2 with Ada.IO_Exceptions;
 package Ada.Text_IO is
3 type File_Type is limited private;
4 type File_Mode is (In_File, Out_File, Append_File);
5 type Count is range 0 .. implementation-defined;
 subtype Positive_Count is Count range 1 .. Count'Last;
 Unbounded : constant Count := 0; -- line and page length
6 subtype Field is Integer range 0 .. implementation-defined;
 subtype Number_Base is Integer range 2 .. 16;
7 type Type_Set is (Lower_Case, Upper_Case);
8 -- File Management
```

|                                                                                                                                                                          |      |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| <b>procedure</b> Create (File : <b>in out</b> File_Type;<br>Mode : <b>in</b> File_Mode := Out_File;<br>Name : <b>in</b> String := "";<br>Form : <b>in</b> String := ""); | 9    |
| <b>procedure</b> Open (File : <b>in out</b> File_Type;<br>Mode : <b>in</b> File_Mode;<br>Name : <b>in</b> String;<br>Form : <b>in</b> String := "");                     | 10   |
| <b>procedure</b> Close (File : <b>in out</b> File_Type);                                                                                                                 | 11   |
| <b>procedure</b> Delete (File : <b>in out</b> File_Type);                                                                                                                |      |
| <b>procedure</b> Reset (File : <b>in out</b> File_Type; Mode : <b>in</b> File_Mode);                                                                                     |      |
| <b>procedure</b> Reset (File : <b>in out</b> File_Type);                                                                                                                 |      |
| <b>function</b> Mode (File : <b>in</b> File_Type) <b>return</b> File_Mode;                                                                                               | 12   |
| <b>function</b> Name (File : <b>in</b> File_Type) <b>return</b> String;                                                                                                  |      |
| <b>function</b> Form (File : <b>in</b> File_Type) <b>return</b> String;                                                                                                  |      |
| <b>function</b> Is_Open (File : <b>in</b> File_Type) <b>return</b> Boolean;                                                                                              | 13   |
| <i>-- Control of default input and output files</i>                                                                                                                      | 14   |

{AI95-00360-01} The type File_Type needs finalization (see 7.6). 86/2

 Incompatibilities With Ada 83

Append_File is a new element of enumeration type File_Mode. 86.a

 Extensions to Ada 83

Get_Immediate, Look_Ahead, the subprograms for dealing with standard error, the type File_Access and its associated 86.b
subprograms, and the generic packages Modular_IO and Decimal_IO are new in Ada 95.

```

*Incompatibilities With Ada 95*

- 86.c/2 {A195-00360-01} **Amendment Correction:** Text\_IO.File\_Type is defined to need finalization. If the restriction No\_Nested\_Finalization (see D.7) applies to the partition, and File\_Type does not have a controlled part, it will not be allowed in local objects in Ada 2005 whereas it would be allowed in original Ada 95. Such code is not portable, as another Ada compiler may have a controlled part in File\_Type, and thus would be illegal.

*Wording Changes from Ada 95*

- 86.d/2 {8652/0051} {A195-00057-01} **Corrigendum:** Corrected the parameter mode of Flush; otherwise it could not be used on Standard\_Output.
- 86.e/2 {A195-00301-01} The Text\_IO.Get\_Line functions are new; they are described in A.10.7, “Input-Output of Characters and Strings”.

**A.10.2 Text File Management***Static Semantics*

1 The only allowed file modes for text files are the modes In\_File, Out\_File, and Append\_File. The subprograms given in subclause A.8.2 for the control of external files, and the function End\_Of\_File given in subclause A.8.3 for sequential input-output, are also available for text files. There is also a version of End\_Of\_File that refers to the current default input file. For text files, the procedures have the following additional effects:

- 2 • For the procedures Create and Open: After a file with mode Out\_File or Append\_File is opened, the page length and line length are unbounded (both have the conventional value zero). After a file (of any mode) is opened, the current column, current line, and current page numbers are set to one. If the mode is Append\_File, it is implementation defined whether a page terminator will separate preexisting text in the file from the new text to be written.

2.a **Reason:** For a file with mode Append\_File, although it may seem more sensible for Open to set the current column, line, and page number based on the number of pages in the file, the number of lines on the last page, and the number of columns in the last line, we rejected this approach because of implementation costs; it would require the implementation to scan the file before doing the append, or to do processing that would be equivalent in effect.

2.b For similar reasons, there is no requirement to erase the last page terminator of the file, nor to insert an explicit page terminator in the case when the final page terminator of a file is represented implicitly by the implementation.

- 3 • For the procedure Close: If the file has the current mode Out\_File or Append\_File, has the effect of calling New\_Page, unless the current page is already terminated; then outputs a file terminator.

- 4 • For the procedure Reset: If the file has the current mode Out\_File or Append\_File, has the effect of calling New\_Page, unless the current page is already terminated; then outputs a file terminator. The current column, line, and page numbers are set to one, and the line and page lengths to Unbounded. If the new mode is Append\_File, it is implementation defined whether a page terminator will separate preexisting text in the file from the new text to be written.

4.a **Reason:** The behavior of Reset should be similar to closing a file and reopening it with the given mode

5 The exception Mode\_Error is propagated by the procedure Reset upon an attempt to change the mode of a file that is the current default input file, the current default output file, or the current default error file.

## NOTES

6 27 An implementation can define the Form parameter of Create and Open to control effects including the following:

- 7 • the interpretation of line and column numbers for an interactive file, and
- 8 • the interpretation of text formats in a file created by a foreign program.

### A.10.3 Default Input, Output, and Error Files

#### *Static Semantics*

The following subprograms provide for the control of the particular default files that are used when a file parameter is omitted from a Get, Put, or other operation of text input-output described below, or when application-dependent error-related text is to be output.

```
procedure Set_Input (File : in File_Type);
```

Operates on a file of mode In\_File. Sets the current default input file to File.

The exception Status\_Error is propagated if the given file is not open. The exception Mode\_Error is propagated if the mode of the given file is not In\_File.

```
procedure Set_Output (File : in File_Type);
```

```
procedure Set_Error (File : in File_Type);
```

Each operates on a file of mode Out\_File or Append\_File. Set\_Output sets the current default output file to File. Set\_Error sets the current default error file to File. The exception Status\_Error is propagated if the given file is not open. The exception Mode\_Error is propagated if the mode of the given file is not Out\_File or Append\_File.

```
function Standard_Input return File_Type;
```

```
function Standard_Input return File_Access;
```

Returns the standard input file (see A.10), or an access value designating the standard input file, respectively.

```
function Standard_Output return File_Type;
```

```
function Standard_Output return File_Access;
```

Returns the standard output file (see A.10) or an access value designating the standard output file, respectively.

```
function Standard_Error return File_Type;
```

```
function Standard_Error return File_Access;
```

{8652/0052} {A195-00194-01} Returns the standard error file (see A.10), or an access value designating the standard error file, respectively.

The Form strings implicitly associated with the opening of Standard\_Input, Standard\_Output, and Standard\_Error at the start of program execution are implementation defined.

```
function Current_Input return File_Type;
```

```
function Current_Input return File_Access;
```

Returns the current default input file, or an access value designating the current default input file, respectively.

```
function Current_Output return File_Type;
```

```
function Current_Output return File_Access;
```

Returns the current default output file, or an access value designating the current default output file, respectively.

```
function Current_Error return File_Type;
```

```
function Current_Error return File_Access;
```

Returns the current default error file, or an access value designating the current default error file, respectively.

20/1        {8652/0051} {AI95-00057-01} **procedure** Flush (File : **in** File\_Type);  
**procedure** Flush;

21            The effect of Flush is the same as the corresponding subprogram in Streams.Stream\_IO (see A.12.1). If File is not explicitly specified, Current\_Output is used.

*Erroneous Execution*

22/1        {8652/0053} {AI95-00063-01} The execution of a program is erroneous if it invokes an operation on a current default input, default output, or default error file, and if the corresponding file object is closed or no longer exists.

22.a.1/1        **Ramification:** {8652/0053} {AI95-00063-01} Closing a default file, then setting the default file to another open file before accessing it is not erroneous.

23/1        *This paragraph was deleted.* {8652/0053} {AI95-00063-01}

NOTES

24            28 The standard input, standard output, and standard error files cannot be opened, closed, reset, or deleted, because the parameter File of the corresponding procedures has the mode **in out**.

25            29 The standard input, standard output, and standard error files are different file objects, but not necessarily different external files.

*Wording Changes from Ada 95*

25.a/2        {8652/0051} {AI95-00057-01} **Corrigendum:** Corrected the parameter mode of Flush; otherwise it could not be used on Standard\_Output.

25.b/2        {8652/0052} {AI95-00194-01} **Corrigendum:** Corrected Standard\_Error so it refers to the correct file.

25.c/2        {8652/0053} {AI95-00063-01} **Corrigendum:** Clarified that execution is erroneous only when a closed default file is accessed.

## A.10.4 Specification of Line and Page Lengths

*Static Semantics*

1            The subprograms described in this subclause are concerned with the line and page structure of a file of mode Out\_File or Append\_File. They operate either on the file given as the first parameter, or, in the absence of such a file parameter, on the current default output file. They provide for output of text with a specified maximum line length or page length. In these cases, line and page terminators are output implicitly and automatically when needed. When line and page lengths are unbounded (that is, when they have the conventional value zero), as in the case of a newly opened file, new lines and new pages are only started when explicitly called for.

2            In all cases, the exception Status\_Error is propagated if the file to be used is not open; the exception Mode\_Error is propagated if the mode of the file is not Out\_File or Append\_File.

3            **procedure** Set\_Line\_Length(File : **in** File\_Type; To : **in** Count);  
**procedure** Set\_Line\_Length(To : **in** Count);

4            Sets the maximum line length of the specified output or append file to the number of characters specified by To. The value zero for To specifies an unbounded line length.

4.a          **Ramification:** The setting does not affect the lengths of lines in the existing file, rather it only influences subsequent output operations.

5            The exception Use\_Error is propagated if the specified line length is inappropriate for the associated external file.

```
procedure Set_Page_Length(File : in File_Type; To : in Count); 6
procedure Set_Page_Length(To : in Count);
```

Sets the maximum page length of the specified output or append file to the number of lines specified by To. The value zero for To specifies an unbounded page length. 7

The exception Use\_Error is propagated if the specified page length is inappropriate for the associated external file. 8

```
function Line_Length(File : in File_Type) return Count; 9
function Line_Length return Count;
```

Returns the maximum line length currently set for the specified output or append file, or zero if the line length is unbounded. 10

```
function Page_Length(File : in File_Type) return Count; 11
function Page_Length return Count;
```

Returns the maximum page length currently set for the specified output or append file, or zero if the page length is unbounded. 12

## A.10.5 Operations on Columns, Lines, and Pages

### *Static Semantics*

The subprograms described in this subclause provide for explicit control of line and page structure; they operate either on the file given as the first parameter, or, in the absence of such a file parameter, on the appropriate (input or output) current default file. The exception Status\_Error is propagated by any of these subprograms if the file to be used is not open. 1

```
procedure New_Line(File : in File_Type; Spacing : in Positive_Count := 1); 2
procedure New_Line(Spacing : in Positive_Count := 1);
```

Operates on a file of mode Out\_File or Append\_File. 3

For a Spacing of one: Outputs a line terminator and sets the current column number to one. Then increments the current line number by one, except in the case that the current line number is already greater than or equal to the maximum page length, for a bounded page length; in that case a page terminator is output, the current page number is incremented by one, and the current line number is set to one. 4

For a Spacing greater than one, the above actions are performed Spacing times. 5

The exception Mode\_Error is propagated if the mode is not Out\_File or Append\_File. 6

```
procedure Skip_Line(File : in File_Type; Spacing : in Positive_Count := 1); 7
procedure Skip_Line(Spacing : in Positive_Count := 1);
```

Operates on a file of mode In\_File. 8

For a Spacing of one: Reads and discards all characters until a line terminator has been read, and then sets the current column number to one. If the line terminator is not immediately followed by a page terminator, the current line number is incremented by one. Otherwise, if the line terminator is immediately followed by a page terminator, then the page terminator is skipped, the current page number is incremented by one, and the current line number is set to one. 9

For a Spacing greater than one, the above actions are performed Spacing times. 10

The exception Mode\_Error is propagated if the mode is not In\_File. The exception End\_Error is propagated if an attempt is made to read a file terminator. 11

12     **function** End\_Of\_Line(File : **in** File\_Type) **return** Boolean;  
**function** End\_Of\_Line **return** Boolean;

13/3     {AI05-0264-1} Operates on a file of mode In\_File. Returns True if a line terminator or a file terminator is next; otherwise, returns False.

14     The exception Mode\_Error is propagated if the mode is not In\_File.

15     **procedure** New\_Page(File : **in** File\_Type);  
**procedure** New\_Page;

16     Operates on a file of mode Out\_File or Append\_File. Outputs a line terminator if the current line is not terminated, or if the current page is empty (that is, if the current column and line numbers are both equal to one). Then outputs a page terminator, which terminates the current page. Adds one to the current page number and sets the current column and line numbers to one.

17     The exception Mode\_Error is propagated if the mode is not Out\_File or Append\_File.

18     **procedure** Skip\_Page(File : **in** File\_Type);  
**procedure** Skip\_Page;

19     Operates on a file of mode In\_File. Reads and discards all characters and line terminators until a page terminator has been read. Then adds one to the current page number, and sets the current column and line numbers to one.

20     The exception Mode\_Error is propagated if the mode is not In\_File. The exception End\_Error is propagated if an attempt is made to read a file terminator.

21     **function** End\_Of\_Page(File : **in** File\_Type) **return** Boolean;  
**function** End\_Of\_Page **return** Boolean;

22/3     {AI05-0264-1} Operates on a file of mode In\_File. Returns True if the combination of a line terminator and a page terminator is next, or if a file terminator is next; otherwise, returns False.

23     The exception Mode\_Error is propagated if the mode is not In\_File.

24     **function** End\_Of\_File(File : **in** File\_Type) **return** Boolean;  
**function** End\_Of\_File **return** Boolean;

25/3     {AI05-0264-1} Operates on a file of mode In\_File. Returns True if a file terminator is next, or if the combination of a line, a page, and a file terminator is next; otherwise, returns False.

26     The exception Mode\_Error is propagated if the mode is not In\_File.

27     The following subprograms provide for the control of the current position of reading or writing in a file. In all cases, the default file is the current output file.

28     **procedure** Set\_Col(File : **in** File\_Type; To : **in** Positive\_Count);  
**procedure** Set\_Col(To : **in** Positive\_Count);

29     If the file mode is Out\_File or Append\_File:

- 30     • If the value specified by To is greater than the current column number, outputs spaces, adding one to the current column number after each space, until the current column number equals the specified value. If the value specified by To is equal to the current column number, there is no effect. If the value specified by To is less than the current column number, has the effect of calling New\_Line (with a spacing of one), then outputs (To - 1) spaces, and sets the current column number to the specified value.
- 31     • The exception Layout\_Error is propagated if the value specified by To exceeds Line\_Length when the line length is bounded (that is, when it does not have the conventional value zero).

32     If the file mode is In\_File:

- Reads (and discards) individual characters, line terminators, and page terminators, until the next character to be read has a column number that equals the value specified by To; there is no effect if the current column number already equals this value. Each transfer of a character or terminator maintains the current column, line, and page numbers in the same way as a Get procedure (see A.10.6). (Short lines will be skipped until a line is reached that has a character at the specified column position.) 33
  - The exception End\_Error is propagated if an attempt is made to read a file terminator. 34
- ```

procedure Set_Line(File : in File_Type; To : in Positive_Count);
procedure Set_Line(To : in Positive_Count);

```
- If the file mode is Out_File or Append_File: 36
- {AI05-0038-1} If the value specified by To is greater than the current line number, has the effect of repeatedly calling New_Line (with a spacing of one), until the current line number equals the specified value. If the value specified by To is equal to the current line number, there is no effect. If the value specified by To is less than the current line number, has the effect of calling New_Page followed, if To is greater than 1, by a call of New_Line with a spacing equal to (To - 1). 37/3
 - The exception Layout_Error is propagated if the value specified by To exceeds Page_Length when the page length is bounded (that is, when it does not have the conventional value zero). 38
- If the mode is In_File: 39
- Has the effect of repeatedly calling Skip_Line (with a spacing of one), until the current line number equals the value specified by To; there is no effect if the current line number already equals this value. (Short pages will be skipped until a page is reached that has a line at the specified line position.) 40
 - The exception End_Error is propagated if an attempt is made to read a file terminator. 41
- ```

function Col(File : in File_Type) return Positive_Count;
function Col return Positive_Count;

```
- Returns the current column number. 43
- The exception Layout\_Error is propagated if this number exceeds Count'Last. 44
- ```

function Line(File : in File_Type) return Positive_Count;
function Line return Positive_Count;

```
- Returns the current line number. 46
- The exception Layout_Error is propagated if this number exceeds Count'Last. 47
- ```

function Page(File : in File_Type) return Positive_Count;
function Page return Positive_Count;

```
- Returns the current page number. 49
- The exception Layout\_Error is propagated if this number exceeds Count'Last. 50
- The column number, line number, or page number are allowed to exceed Count'Last (as a consequence of the input or output of sufficiently many characters, lines, or pages). These events do not cause any exception to be propagated. However, a call of Col, Line, or Page propagates the exception Layout\_Error if the corresponding number exceeds Count'Last. 51
- NOTES 52
- 30 A page terminator is always skipped whenever the preceding line terminator is skipped. An implementation may represent the combination of these terminators by a single character, provided that it is properly recognized on input.

- 52.a/3 {AI05-0038-1} **Correction:** Fixed a glitch in Set\_Line such that we could have called New\_Line(0), which would have to raise Constraint\_Error. It's now defined to work. The bug occurred in Ada 95 and Ada 2005. It's very unlikely that any real programs depend on this exception being raised.

## A.10.6 Get and Put Procedures

### Static Semantics

- 1 The procedures Get and Put for items of the type Character, String, numeric types, and enumeration types are described in subsequent subclauses. Features of these procedures that are common to most of these types are described in this subclause. The Get and Put procedures for items of type Character and String deal with individual character values; the Get and Put procedures for numeric and enumeration types treat the items as lexical elements.
- 2 All procedures Get and Put have forms with a file parameter, written first. Where this parameter is omitted, the appropriate (input or output) current default file is understood to be specified. Each procedure Get operates on a file of mode In\_File. Each procedure Put operates on a file of mode Out\_File or Append\_File.
- 3 All procedures Get and Put maintain the current column, line, and page numbers of the specified file: the effect of each of these procedures upon these numbers is the result of the effects of individual transfers of characters and of individual output or skipping of terminators. Each transfer of a character adds one to the current column number. Each output of a line terminator sets the current column number to one and adds one to the current line number. Each output of a page terminator sets the current column and line numbers to one and adds one to the current page number. For input, each skipping of a line terminator sets the current column number to one and adds one to the current line number; each skipping of a page terminator sets the current column and line numbers to one and adds one to the current page number. Similar considerations apply to the procedures Get\_Line, Put\_Line, and Set\_Col.
- 4 Several Get and Put procedures, for numeric and enumeration types, have *format* parameters which specify field lengths; these parameters are of the nonnegative subtype Field of the type Integer.
- 5/2 {AI95-00223-01} Input-output of enumeration values uses the syntax of the corresponding lexical elements. Any Get procedure for an enumeration type begins by skipping any leading blanks, or line or page terminators. A *blank* is defined as a space or a horizontal tabulation character. Next, characters are input only so long as the sequence input is an initial sequence of an identifier or of a character literal (in particular, input ceases when a line terminator is encountered). The character or line terminator that causes input to cease remains available for subsequent input.
- 6 For a numeric type, the Get procedures have a format parameter called Width. If the value given for this parameter is zero, the Get procedure proceeds in the same manner as for enumeration types, but using the syntax of numeric literals instead of that of enumeration literals. If a nonzero value is given, then exactly Width characters are input, or the characters up to a line terminator, whichever comes first; any skipped leading blanks are included in the count. The syntax used for numeric literals is an extended syntax that allows a leading sign (but no intervening blanks, or line or page terminators) and that also allows (for real types) an integer literal as well as forms that have digits only before the point or only after the point.
- 7 Any Put procedure, for an item of a numeric or an enumeration type, outputs the value of the item as a numeric literal, identifier, or character literal, as appropriate. This is preceded by leading spaces if required by the format parameters Width or Fore (as described in later subclauses), and then a minus sign for a negative value; for an enumeration type, the spaces follow instead of leading. The format given for a Put procedure is overridden if it is insufficiently wide, by using the minimum needed width.

Two further cases arise for Put procedures for numeric and enumeration types, if the line length of the specified output file is bounded (that is, if it does not have the conventional value zero). If the number of characters to be output does not exceed the maximum line length, but is such that they cannot fit on the current line, starting from the current column, then (in effect) `New_Line` is called (with a spacing of one) before output of the item. Otherwise, if the number of characters exceeds the maximum line length, then the exception `Layout_Error` is propagated and nothing is output.

The exception `Status_Error` is propagated by any of the procedures `Get`, `Get_Line`, `Put`, and `Put_Line` if the file to be used is not open. The exception `Mode_Error` is propagated by the procedures `Get` and `Get_Line` if the mode of the file to be used is not `In_File`; and by the procedures `Put` and `Put_Line`, if the mode is not `Out_File` or `Append_File`.

The exception `End_Error` is propagated by a `Get` procedure if an attempt is made to skip a file terminator. The exception `Data_Error` is propagated by a `Get` procedure if the sequence finally input is not a lexical element corresponding to the type, in particular if no characters were input; for this test, leading blanks are ignored; for an item of a numeric type, when a sign is input, this rule applies to the succeeding numeric literal. The exception `Layout_Error` is propagated by a `Put` procedure that outputs to a parameter of type `String`, if the length of the actual string is insufficient for the output of the item.

#### Examples

In the examples, here and in subclauses A.10.8 and A.10.9, the string quotes and the lower case letter b are not transferred: they are shown only to reveal the layout and spaces.

```
N : Integer;
...
Get (N);
-- Characters at input Sequence input Value of N
-- bb-12535b -12535 -12535
-- bb12_535e1b 12_535e1 125350
-- bb12_535e; 12_535e (none) Data_Error raised
```

Example of overridden width parameter:

```
Put (Item => -23, Width => 2); -- "-23"
```

#### Wording Changes from Ada 95

{AI95-00223-01} Removed conflicting text describing the skipping of blanks for a `Get` procedure.

## A.10.7 Input-Output of Characters and Strings

#### Static Semantics

For an item of type `Character` the following procedures are provided:

```
procedure Get (File : in File_Type; Item : out Character);
procedure Get (Item : out Character);
```

After skipping any line terminators and any page terminators, reads the next character from the specified input file and returns the value of this character in the out parameter `Item`.

The exception `End_Error` is propagated if an attempt is made to skip a file terminator.

5     **procedure** Put(File : **in** File\_Type; Item : **in** Character);  
**procedure** Put(Item : **in** Character);

6             If the line length of the specified output file is bounded (that is, does not have the conventional value zero), and the current column number exceeds it, has the effect of calling `New_Line` with a spacing of one. Then, or otherwise, outputs the given character to the file.

7     **procedure** Look\_Ahead (File             : **in** File\_Type;  
                          Item             : **out** Character;  
                          End\_Of\_Line    : **out** Boolean);  
**procedure** Look\_Ahead (Item             : **out** Character;  
                          End\_Of\_Line    : **out** Boolean);

8/3             {AI05-0038-1} {AI05-0264-1} `Status_Error` is propagated if the file is not open. `Mode_Error` is propagated if the mode of the file is not `In_File`. Sets `End_Of_Line` to `True` if at end of line, including if at end of page or at end of file; in each of these cases the value of `Item` is not specified. Otherwise, `End_Of_Line` is set to `False` and `Item` is set to the next character (without consuming it) from the file.

9     **procedure** Get\_Immediate(File : **in** File\_Type;  
                              Item : **out** Character);  
**procedure** Get\_Immediate(Item : **out** Character);

10/3            {AI05-0038-1} Reads the next character, either control or graphic, from the specified `File` or the default input file. `Status_Error` is propagated if the file is not open. `Mode_Error` is propagated if the mode of the file is not `In_File`. `End_Error` is propagated if at the end of the file. The current column, line and page numbers for the file are not affected.

11     **procedure** Get\_Immediate(File         : **in** File\_Type;  
                              Item         : **out** Character;  
                              Available    : **out** Boolean);  
**procedure** Get\_Immediate(Item         : **out** Character;  
                              Available    : **out** Boolean);

12/3            {AI05-0038-1} If a character, either control or graphic, is available from the specified `File` or the default input file, then the character is read; `Available` is `True` and `Item` contains the value of this character. If a character is not available, then `Available` is `False` and the value of `Item` is not specified. `Status_Error` is propagated if the file is not open. `Mode_Error` is propagated if the mode of the file is not `In_File`. `End_Error` is propagated if at the end of the file. The current column, line and page numbers for the file are not affected.

13/2     {AI95-00301-01} For an item of type `String` the following subprograms are provided:

14     **procedure** Get(File : **in** File\_Type; Item : **out** String);  
**procedure** Get(Item : **out** String);

15             Determines the length of the given string and attempts that number of `Get` operations for successive characters of the string (in particular, no operation is performed if the string is null).

16     **procedure** Put(File : **in** File\_Type; Item : **in** String);  
**procedure** Put(Item : **in** String);

17             Determines the length of the given string and attempts that number of `Put` operations for successive characters of the string (in particular, no operation is performed if the string is null).

17.1/2     **function** Get\_Line(File : **in** File\_Type) **return** String;  
**function** Get\_Line **return** String;

17.2/2             {AI95-00301-01} Returns a result string constructed by reading successive characters from the specified input file, and assigning them to successive characters of the result string. The result string has a lower bound of 1 and an upper bound of the number of characters read. Reading stops when the end of the line is met; `Skip_Line` is then (in effect) called with a spacing of 1.

- {AI95-00301-01}* Constraint\_Error is raised if the length of the line exceeds Positive'Last; in this case, the line number and page number are unchanged, and the column number is unspecified but no less than it was before the call. The exception End\_Error is propagated if an attempt is made to skip a file terminator. 17.3/2
- Ramification:** *{AI95-00301-01}* Precisely what is left in the file is unspecified if Constraint\_Error is raised because the line doesn't fit in a String; it should be consistent with column number. This allows implementers to use whatever buffering scheme makes sense. But the line terminator is not skipped in this case. 17.a/2
- ```

procedure Get_Line (File : in File_Type;
                    Item : out String;
                    Last : out Natural);
procedure Get_Line (Item : out String;
                    Last : out Natural);

```
- 18
- Reads successive characters from the specified input file and assigns them to successive characters of the specified string. Reading stops if the end of the string is met. Reading also stops if the end of the line is met before meeting the end of the string; in this case Skip_Line is (in effect) called with a spacing of 1. The values of characters not assigned are not specified. 19
- If characters are read, returns in Last the index value such that Item(Last) is the last character assigned (the index of the first character assigned is Item'First). If no characters are read, returns in Last an index value that is one less than Item'First. The exception End_Error is propagated if an attempt is made to skip a file terminator. 20
- ```

procedure Put_Line (File : in File_Type; Item : in String);
procedure Put_Line (Item : in String);

```
- 21
- Calls the procedure Put for the given string, and then the procedure New\_Line with a spacing of one. 22
- Implementation Advice*
- The Get\_Immediate procedures should be implemented with unbuffered input. For a device such as a keyboard, input should be “available” if a key has already been typed, whereas for a disk file, input should always be available except at end of file. For a file associated with a keyboard-like device, any line-editing features of the underlying operating system should be disabled during the execution of Get\_Immediate. 23
- Implementation Advice:** Get\_Immediate should be implemented with unbuffered input; input should be available immediately; line-editing should be disabled. 23.a/2
- NOTES
- 31 Get\_Immediate can be used to read a single key from the keyboard “immediately”; that is, without waiting for an end of line. In a call of Get\_Immediate without the parameter Available, the caller will wait until a character is available. 24
- 32 In a literal string parameter of Put, the enclosing string bracket characters are not output. Each doubled string bracket character in the enclosed string is output as a single string bracket character, as a consequence of the rule for string literals (see 2.6). 25
- 33 A string read by Get or written by Put can extend over several lines. An implementation is allowed to assume that certain external files do not contain page terminators, in which case Get\_Line and Skip\_Line can return as soon as a line terminator is read. 26
- Incompatibilities With Ada 95*
- {AI95-00301-01}* *{AI05-0005-1}* The Get\_Line functions are added to Ada.Text\_IO. If Ada.Text\_IO is referenced in a use\_clause, and a function Get\_Line is defined in a package that is also referenced in a use\_clause, the user-defined Get\_Line may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur. 26.a/3
- Extensions to Ada 95*
- {AI95-00301-01}* The Text\_IO.Get\_Line functions are new. 26.b/2

26.c/3 {AI05-0038-1} **Correction:** Added missing wording about raising Status\_Error to Look\_Ahead and Get\_Immediate.

## A.10.8 Input-Output for Integer Types

### Static Semantics

1 The following procedures are defined in the generic packages Integer\_IO and Modular\_IO, which have to be instantiated for the appropriate signed integer or modular type respectively (indicated by Num in the specifications).

2 Values are output as decimal or based literals, without low line characters or exponent, and, for Integer\_IO, preceded by a minus sign if negative. The format (which includes any leading spaces and minus sign) can be specified by an optional field width parameter. Values of widths of fields in output formats are of the nonnegative integer subtype Field. Values of bases are of the integer subtype Number\_Base.

3 `subtype Number_Base is Integer range 2 .. 16;`

4 The default field width and base to be used by output procedures are defined by the following variables that are declared in the generic packages Integer\_IO and Modular\_IO:

5 `Default_Width : Field := Num'Width;`  
`Default_Base : Number_Base := 10;`

6 The following procedures are provided:

7 `procedure Get(File : in File_Type; Item : out Num; Width : in Field := 0);`  
`procedure Get(Item : out Num; Width : in Field := 0);`

8 If the value of the parameter Width is zero, skips any leading blanks, line terminators, or page terminators, then reads a plus sign if present or (for a signed type only) a minus sign if present, then reads the longest possible sequence of characters matching the syntax of a numeric literal without a point. If a nonzero value of Width is supplied, then exactly Width characters are input, or the characters (possibly none) up to a line terminator, whichever comes first; any skipped leading blanks are included in the count.

9 Returns, in the parameter Item, the value of type Num that corresponds to the sequence input.

10/3 {AI05-0038-1} The exception Data\_Error is propagated if the sequence of characters read does not form a legal integer literal or if the value obtained is not of the subtype Num.

11 `procedure Put(File : in File_Type;`  
`Item : in Num;`  
`Width : in Field := Default_Width;`  
`Base : in Number_Base := Default_Base);`

`procedure Put(Item : in Num;`  
`Width : in Field := Default_Width;`  
`Base : in Number_Base := Default_Base);`

12 Outputs the value of the parameter Item as an integer literal, with no low lines, no exponent, and no leading zeros (but a single zero for the value zero), and a preceding minus sign for a negative value.

13 If the resulting sequence of characters to be output has fewer than Width characters, then leading spaces are first output to make up the difference.

14 Uses the syntax for decimal literal if the parameter Base has the value ten (either explicitly or through Default\_Base); otherwise, uses the syntax for based literal, with any letters in upper case.

```
procedure Get(From : in String; Item : out Num; Last : out Positive);
```

 15

Reads an integer value from the beginning of the given string, following the same rules as the Get procedure that reads an integer value from a file, but treating the end of the string as a file terminator. Returns, in the parameter Item, the value of type Num that corresponds to the sequence input. Returns in Last the index value such that From(Last) is the last character read. 16

The exception Data\_Error is propagated if the sequence input does not have the required syntax or if the value obtained is not of the subtype Num. 17

```
procedure Put(To : out String;
 Item : in Num;
 Base : in Number_Base := Default_Base);
```

 18

Outputs the value of the parameter Item to the given string, following the same rule as for output to a file, using the length of the given string as the value for Width. 19

Integer\_Text\_IO is a library package that is a nongeneric equivalent to Text\_IO.Integer\_IO for the predefined type Integer: 20

```
with Ada.Text_IO;
package Ada.Integer_Text_IO is new Ada.Text_IO.Integer_IO(Integer);
```

 21

For each predefined signed integer type, a nongeneric equivalent to Text\_IO.Integer\_IO is provided, with names such as Ada.Long\_Integer\_Text\_IO. 22

#### *Implementation Permissions*

The nongeneric equivalent packages may, but need not, be actual instantiations of the generic package for the appropriate predefined type. 23

*Paragraphs 24 and 25 were deleted.*

#### *Examples*

```
{AI05-0298-1} subtype Byte_Int is Integer range -127 .. 127;
package Int_IO is new Integer_IO(Byte_Int); use Int_IO;
-- default format used at instantiation,
-- Default_Width = 4, Default_Base = 10

Put (126); -- "b126"
Put (-126, 7); -- "bbb-126"
Put (126, Width => 13, Base => 2); -- "bbb2#1111110#"
```

 26/3 27

#### *Inconsistencies With Ada 2005*

{AI05-0038-1} **Correction:** Changed wording to make Integer\_IO and Modular\_IO raise Data\_Error in the same way when the bounds of the subtype are exceeded. There is no value to different behavior, and all surveyed compilers already treat integer and modular values the same way. This could only cause a problem if a program was compiled with some unsurveyed compiler, and the Ada 95-defined behavior is expected for Modular\_IO. But note that such code is not portable anyway, as most widely used compilers behave consistently with the new wording, so it is unlikely that such code exists. 27.a/3

## A.10.9 Input-Output for Real Types

### *Static Semantics*

The following procedures are defined in the generic packages Float\_IO, Fixed\_IO, and Decimal\_IO, which have to be instantiated for the appropriate floating point, ordinary fixed point, or decimal fixed point type respectively (indicated by Num in the specifications). 1

2 Values are output as decimal literals without low line characters. The format of each value output consists of a Fore field, a decimal point, an Aft field, and (if a nonzero Exp parameter is supplied) the letter E and an Exp field. The two possible formats thus correspond to:

3     Fore . Aft

4 and to:

5     Fore . Aft E Exp

6 without any spaces between these fields. The Fore field may include leading spaces, and a minus sign for negative values. The Aft field includes only decimal digits (possibly with trailing zeros). The Exp field includes the sign (plus or minus) and the exponent (possibly with leading zeros).

7 For floating point types, the default lengths of these fields are defined by the following variables that are declared in the generic package Float\_IO:

8     Default\_Fore : Field := 2;  
    Default\_Aft : Field := Num'Digits-1;  
    Default\_Exp : Field := 3;

9 For ordinary or decimal fixed point types, the default lengths of these fields are defined by the following variables that are declared in the generic packages Fixed\_IO and Decimal\_IO, respectively:

10     Default\_Fore : Field := Num'Fore;  
    Default\_Aft : Field := Num'Aft;  
    Default\_Exp : Field := 0;

11 The following procedures are provided:

12     **procedure** Get(File : **in** File\_Type; Item : **out** Num; Width : **in** Field := 0);  
    **procedure** Get(Item : **out** Num; Width : **in** Field := 0);

13     If the value of the parameter Width is zero, skips any leading blanks, line terminators, or page terminators, then reads the longest possible sequence of characters matching the syntax of any of the following (see 2.4):

- 14     • [+|-]numeric\_literal
- 15     • [+|-]numeral.[exponent]
- 16     • [+|-].numeral[exponent]
- 17     • [+|-]base#based\_numeral#[exponent]
- 18     • [+|-]base#.based\_numeral#[exponent]

19     If a nonzero value of Width is supplied, then exactly Width characters are input, or the characters (possibly none) up to a line terminator, whichever comes first; any skipped leading blanks are included in the count.

20     Returns in the parameter Item the value of type Num that corresponds to the sequence input, preserving the sign (positive if none has been specified) of a zero value if Num is a floating point type and Num'Signed\_Zeros is True.

21     The exception Data\_Error is propagated if the sequence input does not have the required syntax or if the value obtained is not of the subtype Num.

```

procedure Put (File : in File_Type;
 Item : in Num;
 Fore : in Field := Default_Fore;
 Aft : in Field := Default_Aft;
 Exp : in Field := Default_Exp);

```

```

procedure Put (Item : in Num;
 Fore : in Field := Default_Fore;
 Aft : in Field := Default_Aft;
 Exp : in Field := Default_Exp);

```

Outputs the value of the parameter Item as a decimal literal with the format defined by Fore, Aft and Exp. If the value is negative, or if Num is a floating point type where Num'Signed\_Zeros is True and the value is a negatively signed zero, then a minus sign is included in the integer part. If Exp has the value zero, then the integer part to be output has as many digits as are needed to represent the integer part of the value of Item, overriding Fore if necessary, or consists of the digit zero if the value of Item has no integer part.

If Exp has a value greater than zero, then the integer part to be output has a single digit, which is nonzero except for the value 0.0 of Item.

In both cases, however, if the integer part to be output has fewer than Fore characters, including any minus sign, then leading spaces are first output to make up the difference. The number of digits of the fractional part is given by Aft, or is one if Aft equals zero. The value is rounded; a value of exactly one half in the last place is rounded away from zero.

If Exp has the value zero, there is no exponent part. If Exp has a value greater than zero, then the exponent part to be output has as many digits as are needed to represent the exponent part of the value of Item (for which a single digit integer part is used), and includes an initial sign (plus or minus). If the exponent part to be output has fewer than Exp characters, including the sign, then leading zeros precede the digits, to make up the difference. For the value 0.0 of Item, the exponent has the value zero.

```

procedure Get (From : in String; Item : out Num; Last : out Positive);

```

Reads a real value from the beginning of the given string, following the same rule as the Get procedure that reads a real value from a file, but treating the end of the string as a file terminator. Returns, in the parameter Item, the value of type Num that corresponds to the sequence input. Returns in Last the index value such that From(Last) is the last character read.

The exception Data\_Error is propagated if the sequence input does not have the required syntax, or if the value obtained is not of the subtype Num.

```

procedure Put (To : out String;
 Item : in Num;
 Aft : in Field := Default_Aft;
 Exp : in Field := Default_Exp);

```

Outputs the value of the parameter Item to the given string, following the same rule as for output to a file, using a value for Fore such that the sequence of characters output exactly fills the string, including any leading spaces.

Float\_Text\_IO is a library package that is a nongeneric equivalent to Text\_IO.Float\_IO for the predefined type Float:

```

with Ada.Text_IO;
package Ada.Float_Text_IO is new Ada.Text_IO.Float_IO(Float);

```

For each predefined floating point type, a nongeneric equivalent to Text\_IO.Float\_IO is provided, with names such as Ada.Long\_Float\_Text\_IO.

*Implementation Permissions*

- 35 An implementation may extend Get [and Put] for floating point types to support special values such as infinities and NaNs.
- 35.a/3 **Discussion:** {A105-0005-1} See also the similar permission for the Wide\_Wide\_Value, Wide\_Value, and Value attributes in 3.5.
- 36 The implementation of Put need not produce an output value with greater accuracy than is supported for the base subtype. The additional accuracy, if any, of the value produced by Put when the number of requested digits in the integer and fractional parts exceeds the required accuracy is implementation defined.
- 36.a **Discussion:** The required accuracy is thus Num'Base'Digits digits if Num is a floating point subtype. For a fixed point subtype the required accuracy is a function of the subtype's Fore, Aft, and Delta attributes.
- 36.b **Implementation defined:** The accuracy of the value produced by Put.
- 37 The nongeneric equivalent packages may, but need not, be actual instantiations of the generic package for the appropriate predefined type.
- NOTES
- 38 34 For an item with a positive value, if output to a string exactly fills the string without leading spaces, then output of the corresponding negative value will propagate Layout\_Error.
- 39 35 The rules for the Value attribute (see 3.5) and the rules for Get are based on the same set of formats.

*Examples*

40/1 *This paragraph was deleted.*

```

41 package Real_IO is new Float_IO(Real) ; use Real_IO ;
 -- default format used at instantiation, Default_Exp = 3
42 X : Real := -123.4567 ; -- digits 8 (see 3.5.7)
43 Put(X) ; -- default format "-1.2345670E+02"
 Put(X, Fore => 5, Aft => 3, Exp => 2) ; -- "bbb-1.235E+2"
 Put(X, 5, 3, 0) ; -- "b-123.457"
```

**A.10.10 Input-Output for Enumeration Types***Static Semantics*

- 1 The following procedures are defined in the generic package Enumeration\_IO, which has to be instantiated for the appropriate enumeration type (indicated by Enum in the specification).
- 2 Values are output using either upper or lower case letters for identifiers. This is specified by the parameter Set, which is of the enumeration type Type\_Set.
- 3 **type** Type\_Set **is** (Lower\_Case, Upper\_Case) ;
- 4 The format (which includes any trailing spaces) can be specified by an optional field width parameter. The default field width and letter case are defined by the following variables that are declared in the generic package Enumeration\_IO:
- 5 Default\_Width : Field := 0 ;  
 Default\_Setting : Type\_Set := Upper\_Case ;
- 6 The following procedures are provided:
- 7 **procedure** Get(File : **in** File\_Type; Item : **out** Enum) ;  
**procedure** Get(Item : **out** Enum) ;
- 8 After skipping any leading blanks, line terminators, or page terminators, reads an identifier according to the syntax of this lexical element (lower and upper case being considered equivalent), or a character literal according to the syntax of this lexical element (including the

apostrophes). Returns, in the parameter `Item`, the value of type `Enum` that corresponds to the sequence input.

The exception `Data_Error` is propagated if the sequence input does not have the required syntax, or if the identifier or character literal does not correspond to a value of the subtype `Enum`. 9

```
procedure Put (File : in File_Type;
 Item : in Enum;
 Width : in Field := Default_Width;
 Set : in Type_Set := Default_Setting);
```

 10

```
procedure Put (Item : in Enum;
 Width : in Field := Default_Width;
 Set : in Type_Set := Default_Setting);
```

Outputs the value of the parameter `Item` as an enumeration literal (either an identifier or a character literal). The optional parameter `Set` indicates whether lower case or upper case is used for identifiers; it has no effect for character literals. If the sequence of characters produced has fewer than `Width` characters, then trailing spaces are finally output to make up the difference. If `Enum` is a character type, the sequence of characters produced is as for `Enum'Image(Item)`, as modified by the `Width` and `Set` parameters. 11

**Discussion:** *{AI05-0005-1}* For a character type, the literal might be a `Wide_Wide_Character`, `Wide_Character`, or a control character. Whatever `Image` does for these things is appropriate here, too. 11.a/3

*{AI05-0036-1}* The “characters produced” defines the “characters to be output” in the sense of A.10.6, so a result that cannot fit on any bounded line will raise `Layout_Error`. 11.b/3

```
procedure Get (From : in String; Item : out Enum; Last : out Positive);
```

 12

Reads an enumeration value from the beginning of the given string, following the same rule as the `Get` procedure that reads an enumeration value from a file, but treating the end of the string as a file terminator. Returns, in the parameter `Item`, the value of type `Enum` that corresponds to the sequence input. Returns in `Last` the index value such that `From(Last)` is the last character read. 13

The exception `Data_Error` is propagated if the sequence input does not have the required syntax, or if the identifier or character literal does not correspond to a value of the subtype `Enum`. 14

**To be honest:** *{AI05-0005-1}* For a character type, it is permissible for the implementation to make `Get` do the inverse of what `Put` does, in the case of wide and wide\_wide character\_literals and control characters. 14.a/3

```
procedure Put (To : out String;
 Item : in Enum;
 Set : in Type_Set := Default_Setting);
```

 15

Outputs the value of the parameter `Item` to the given string, following the same rule as for output to a file, using the length of the given string as the value for `Width`. 16

*{8652/0054}* *{AI95-00007-01}* Although the specification of the generic package `Enumeration_IO` would allow instantiation for an integer type, this is not the intended purpose of this generic package, and the effect of such instantiations is not defined by the language. 17/1

#### NOTES

36 There is a difference between `Put` defined for characters, and for enumeration values. Thus 18

```
Ada.Text_IO.Put ('A'); -- outputs the character A
```

 19

```
package Char_IO is new Ada.Text_IO.Enumeration_IO (Character);
Char_IO.Put ('A'); -- outputs the character 'A', between apostrophes
```

 20

37 The type `Boolean` is an enumeration type, hence `Enumeration_IO` can be instantiated for this type. 21

#### Wording Changes from Ada 95

*{8652/0054}* *{AI95-00007-01}* **Corrigendum:** Corrected the wording to say `Enumeration_IO` can be instantiated with an integer type, not a float type. 21.a/2

## A.10.11 Input-Output for Bounded Strings

1/2 {AI95-00428-01} The package Text\_IO.Bounded\_IO provides input-output in human-readable form for Bounded\_Strings.

*Static Semantics*

2/2 {AI95-00428-01} The generic library package Text\_IO.Bounded\_IO has the following declaration:

```
3/2 with Ada.Strings.Bounded;
 generic
 with package Bounded is
 new Ada.Strings.Bounded.Generic_Bounded_Length (<>);
 package Ada.Text_IO.Bounded_IO is
4/2 procedure Put
 (File : in File_Type;
 Item : in Bounded.Bounded_String);
5/2 procedure Put
 (Item : in Bounded.Bounded_String);
6/2 procedure Put_Line
 (File : in File_Type;
 Item : in Bounded.Bounded_String);
7/2 procedure Put_Line
 (Item : in Bounded.Bounded_String);
8/2 function Get_Line
 (File : in File_Type)
 return Bounded.Bounded_String;
9/2 function Get_Line
 return Bounded.Bounded_String;
10/2 procedure Get_Line
 (File : in File_Type; Item : out Bounded.Bounded_String);
11/2 procedure Get_Line
 (Item : out Bounded.Bounded_String);
12/2 end Ada.Text_IO.Bounded_IO;
```

13/2 {AI95-00428-01} For an item of type Bounded\_String, the following subprograms are provided:

```
14/2 procedure Put
 (File : in File_Type;
 Item : in Bounded.Bounded_String);
 {AI95-00428-01} Equivalent to Text_IO.Put (File, Bounded.To_String(Item));
16/2 procedure Put
 (Item : in Bounded.Bounded_String);
 {AI95-00428-01} Equivalent to Text_IO.Put (Bounded.To_String(Item));
18/2 procedure Put_Line
 (File : in File_Type;
 Item : in Bounded.Bounded_String);
 {AI95-00428-01} Equivalent to Text_IO.Put_Line (File, Bounded.To_String(Item));
20/2 procedure Put_Line
 (Item : in Bounded.Bounded_String);
 {AI95-00428-01} Equivalent to Text_IO.Put_Line (Bounded.To_String(Item));
22/2 function Get_Line
 (File : in File_Type)
 return Bounded.Bounded_String;
 {AI95-00428-01} Returns Bounded.To_Bounded_String(Text_IO.Get_Line(File));
23/2
```

|                                                                         |        |
|-------------------------------------------------------------------------|--------|

 Extensions to Ada 95
29.a/2 {AI95-00301-01} Package Text_IO.Unbounded_IO is new.

```

## A.11 Wide Text Input-Output and Wide Wide Text Input-Output

1/2 {AI95-00285-01} The packages `Wide_Text_IO` and `Wide_Wide_Text_IO` provide facilities for input and output in human-readable form. Each file is read or written sequentially, as a sequence of wide characters (or wide wide characters) grouped into lines, and as a sequence of lines grouped into pages.

### *Static Semantics*

2/2 {AI95-00285-01} {AI95-00301-01} The specification of package `Wide_Text_IO` is the same as that for `Text_IO`, except that in each `Get`, `Look_Ahead`, `Get_Immediate`, `Get_Line`, `Put`, and `Put_Line` subprogram, any occurrence of `Character` is replaced by `Wide_Character`, and any occurrence of `String` is replaced by `Wide_String`. Nongeneric equivalents of `Wide_Text_IO.Integer_IO` and `Wide_Text_IO.Float_IO` are provided (as for `Text_IO`) for each predefined numeric type, with names such as `Ada.Integer_Wide_Text_IO`, `Ada.Long_Integer_Wide_Text_IO`, `Ada.Float_Wide_Text_IO`, `Ada.Long_Float_Wide_Text_IO`.

3/2 {AI95-00285-01} {AI95-00301-01} The specification of package `Wide_Wide_Text_IO` is the same as that for `Text_IO`, except that in each `Get`, `Look_Ahead`, `Get_Immediate`, `Get_Line`, `Put`, and `Put_Line` subprogram, any occurrence of `Character` is replaced by `Wide_Wide_Character`, and any occurrence of `String` is replaced by `Wide_Wide_String`. Nongeneric equivalents of `Wide_Wide_Text_IO.Integer_IO` and `Wide_Wide_Text_IO.Float_IO` are provided (as for `Text_IO`) for each predefined numeric type, with names such as `Ada.Integer_Wide_Wide_Text_IO`, `Ada.Long_Integer_Wide_Wide_Text_IO`, `Ada.Float_Wide_Wide_Text_IO`, `Ada.Long_Float_Wide_Wide_Text_IO`.

4/3 {AI95-00285-01} {AI95-00428-01} {AI05-0004-1} {AI05-0092-1} The specification of package `Wide_Text_IO.Wide_Bounded_IO` is the same as that for `Text_IO.Bounded_IO`, except that any occurrence of `Bounded_String` is replaced by `Bounded_Wide_String`, and any occurrence of package

Bounded is replaced by Wide\_Bounded. The specification of package Wide\_Wide\_Text\_IO.Wide\_Wide\_Bounded\_IO is the same as that for Text\_IO.Bounded\_IO, except that any occurrence of Bounded\_String is replaced by Bounded\_Wide\_Wide\_String, and any occurrence of package Bounded is replaced by Wide\_Wide\_Bounded.

**To be honest:** {AI05-0005-1} “package Bounded” refers to both the package Ada.Strings.Bounded and the formal package parameter named Bounded. 4.a/3

{AI95-00285-01} {AI95-00301-01} {AI05-0092-1} The specification of package Wide\_Text\_IO.-Wide\_Unbounded\_IO is the same as that for Text\_IO.Unbounded\_IO, except that any occurrence of Unbounded\_String is replaced by Unbounded\_Wide\_String, and any occurrence of package Unbounded is replaced by Wide\_Unbounded. The specification of package Wide\_Wide\_Text\_IO.Wide\_Wide\_Unbounded\_IO is the same as that for Text\_IO.Unbounded\_IO, except that any occurrence of Unbounded\_String is replaced by Unbounded\_Wide\_Wide\_String, and any occurrence of package Unbounded is replaced by Wide\_Wide\_Unbounded. 5/3

#### Extensions to Ada 83

Support for Wide\_Character and Wide\_String I/O is new in Ada 95. 5.a

#### Extensions to Ada 95

{AI95-00285-01} Package Wide\_Wide\_Text\_IO is new. Be glad it wasn't called Double\_Wide\_Text\_IO (for use in trailer parks) or Really\_Wide\_Text\_IO. 5.b/2

{AI95-00301-01} Packages Wide\_Text\_IO.Wide\_Unbounded\_IO and Wide\_Wide\_Text\_IO.Wide\_Wide\_Unbounded\_IO are also new. 5.c/2

{AI95-00428-01} Packages Wide\_Text\_IO.Wide\_Bounded\_IO and Wide\_Wide\_Text\_IO.Wide\_Wide\_Bounded\_IO are new as well. 5.d/2

#### Wording Changes from Ada 2005

{AI05-0092-1} **Correction:** Corrected the names of various entities in the above description. Since the previously named entities don't exist and the intent is obvious, this is just considered a presentation change. 5.e/3

## A.12 Stream Input-Output

{AI95-00285-01} The packages Streams.Stream\_IO, Text\_IO.Text\_Streams, Wide\_Text\_IO.Text\_Streams, and Wide\_Wide\_Text\_IO.Text\_Streams provide stream-oriented operations on files. 1/2

#### Wording Changes from Ada 95

{AI95-00285-01} Included package Wide\_Wide\_Text\_IO.Text\_Streams in this description. 1.a/2

### A.12.1 The Package Streams.Stream\_IO

[The subprograms in the child package Streams.Stream\_IO provide control over stream files. Access to a stream file is either sequential, via a call on Read or Write to transfer an array of stream elements, or positional (if supported by the implementation for the given file), by specifying a relative index for an element. Since a stream file can be converted to a Stream\_Access value, calling stream-oriented attribute subprograms of different element types with the same Stream\_Access value provides heterogeneous input-output.] See 13.13 for a general discussion of streams. 1

#### Static Semantics

{8652/0055} {AI95-00026-01} The elements of a stream file are stream elements. If positioning is supported for the specified external file, a current index and current size are maintained for the file as 1.1/1

described in A.8. If positioning is not supported, a current index is not maintained, and the current size is implementation defined.

1.a.1/1 **Implementation defined:** Current size for a stream file for which positioning is not supported.

2 The library package Streams.Stream\_IO has the following declaration:

```

3/3 {AI05-0283-1} with Ada.IO_Exceptions;
 package Ada.Streams.Stream_IO is
 pragma Preelaborate(Stream_IO);
4 type Stream_Access is access all Root_Stream_Type'Class;
5 type File_Type is limited private;
6 type File_Mode is (In_File, Out_File, Append_File);
7 type Count is range 0 .. implementation-defined;
 subtype Positive_Count is Count range 1 .. Count'Last;
 -- Index into file, in stream elements.
8 procedure Create (File : in out File_Type;
 Mode : in File_Mode := Out_File;

|                                                                           | <i>This paragraph was deleted.</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 31.a/1                     |
|                                                                           | The <code>Set_Index</code> procedure sets the current index to the specified value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 32                         |
| <code>{8652/0055} {AI95-00026-01}</code>                                  | If positioning is supported for the external file, the current index is maintained as follows:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | 32.1/1                     |
|                                                                           | <ul style="list-style-type: none"> <li>• <code>{8652/0055} {AI95-00026-01}</code> For <code>Open</code> and <code>Create</code>, if the <code>Mode</code> parameter is <code>Append_File</code>, the current index is set to the current size of the file plus one; otherwise, the current index is set to one.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | 32.2/1                     |

- 32.3/1 • {8652/0055} {AI95-00026-01} For Reset, if the Mode parameter is Append\_File, or no Mode parameter is given and the current mode is Append\_File, the current index is set to the current size of the file plus one; otherwise, the current index is set to one.
- 32.4/1 • {8652/0055} {AI95-00026-01} For Set\_Mode, if the new mode is Append\_File, the current index is set to current size plus one; otherwise, the current index is unchanged.
- 32.5/1 • {8652/0055} {AI95-00026-01} For Read and Write without a Positive\_Count parameter, the current index is incremented by the number of stream elements read or written.
- 32.6/1 • {8652/0055} {AI95-00026-01} For Read and Write with a Positive\_Count parameter, the value of the current index is set to the value of the Positive\_Count parameter plus the number of stream elements read or written.

33 If positioning is not supported for the given file, then a call of Index or Set\_Index propagates Use\_Error. Similarly, a call of Read or Write with a Positive\_Count parameter propagates Use\_Error.

- 33.a/2 **Implementation Note:** {AI95-00085-01} It is permissible for an implementation to implement mode Append\_File using the Unix append mode (the O\_APPEND bit). Such an implementation does not support positioning when the mode is Append\_File, and therefore the operations listed above must raise Use\_Error. This is acceptable as there is no requirement that any particular file support positioning; therefore it is acceptable that a file support positioning when opened with mode Out\_File, and the same file not support positioning when opened with mode Append\_File. But it is not acceptable for a file to support positioning (by allowing the above operations), but to do something other than the defined semantics (that is, always write at the end, even when explicitly commanded to write somewhere else).

*Paragraphs 34 through 36 were deleted.*

#### *Erroneous Execution*

- 36.1/1 {8652/0056} {AI95-00001-01} If the File\_Type object passed to the Stream function is later closed or finalized, and the stream-oriented attributes are subsequently called (explicitly or implicitly) on the Stream\_Access value returned by Stream, execution is erroneous. This rule applies even if the File\_Type object was opened again after it had been closed.

- 36.a.1/1 **Reason:** These rules are analogous to the rule for the result of the Current\_Input, Current\_Output, and Current\_Error functions. These rules make it possible to represent a value of (some descendant of) Root\_Stream\_Type which represents a file as an access value, with a null value corresponding to a closed file.

#### *Inconsistencies With Ada 95*

- 36.a/3 {AI95-00283-01} {AI05-0005-1} **Amendment Correction:** The description of the subprograms for managing files was corrected so that they do not require truncation of the external file — a stream file is not a sequential file. An Ada 95 program that expects truncation of the stream file might not work under Ada 2005. Note that the Ada 95 standard was ambiguous on this point (the normative wording seemed to require truncation, but didn't explain where; the AARM notes seemed to expect behavior like Direct\_IO), and implementations varied widely. Therefore, as a practical matter, code that depends on stream truncation might not work even in Ada 95; deleting the file before opening it provides truncation that works in both Ada 95 and Ada 2005.

#### *Incompatibilities With Ada 95*

- 36.b/2 {AI95-00360-01} **Amendment Correction:** Stream\_IO.File\_Type is defined to need finalization. If the restriction No\_Nested\_Finalization (see D.7) applies to the partition, and File\_Type does not have a controlled part, it will not be allowed in local objects in Ada 2005 whereas it would be allowed in original Ada 95. Such code is not portable, as another Ada compiler may have a controlled part in File\_Type, and thus would be illegal.

#### *Wording Changes from Ada 95*

- 36.c/2 {8652/0051} {AI95-00057-01} **Corrigendum:** Corrected the parameter mode of Flush; otherwise it could not be used on Standard\_Output.
- 36.d/2 {8652/0055} {AI95-00026-01} {AI95-00256-01} **Corrigendum:** Added wording to describe the effects of the various operations on the current index. The Amendment adds an explanation of the use of current index for Read and Write.
- 36.e/2 {8652/0056} {AI95-00001-01} **Corrigendum:** Clarified that Stream can raise Status\_Error, and clarified that using a Stream\_Access whose file has been closed is erroneous.

{AI95-00085-01} Clarified that Set\_Mode can be called with the current mode. 36.f/2

*Extensions to Ada 2005*

{AI05-0283-1} Package Ada.Streams.Stream\_IO is now preelaborated, allowing it to be used in more contexts (including in distributed systems). Note that is *not* a remote types package; File\_Type objects cannot be passed between partitions. 36.g/3

## A.12.2 The Package Text\_IO.Text\_Streams

The package Text\_IO.Text\_Streams provides a function for treating a text file as a stream. 1

*Static Semantics*

The library package Text\_IO.Text\_Streams has the following declaration: 2

```
with Ada.Streams;
package Ada.Text_IO.Text_Streams is
 type Stream_Access is access all Streams.Root_Stream_Type'Class;
 function Stream (File : in File_Type) return Stream_Access;
end Ada.Text_IO.Text_Streams; 3 4
```

The Stream function has the same effect as the corresponding function in Streams.Stream\_IO. 5

NOTES

38 The ability to obtain a stream for a text file allows Current\_Input, Current\_Output, and Current\_Error to be processed with the functionality of streams, including the mixing of text and binary input-output, and the mixing of binary input-output for different types. 6

39 Performing operations on the stream associated with a text file does not affect the column, line, or page counts. 7

## A.12.3 The Package Wide\_Text\_IO.Text\_Streams

The package Wide\_Text\_IO.Text\_Streams provides a function for treating a wide text file as a stream. 1

*Static Semantics*

The library package Wide\_Text\_IO.Text\_Streams has the following declaration: 2

```
with Ada.Streams;
package Ada.Wide_Text_IO.Text_Streams is
 type Stream_Access is access all Streams.Root_Stream_Type'Class;
 function Stream (File : in File_Type) return Stream_Access;
end Ada.Wide_Text_IO.Text_Streams; 3 4
```

The Stream function has the same effect as the corresponding function in Streams.Stream\_IO. 5

## A.12.4 The Package Wide\_Wide\_Text\_IO.Text\_Streams

{AI95-00285-01} The package Wide\_Wide\_Text\_IO.Text\_Streams provides a function for treating a wide wide text file as a stream. 1/2

*Static Semantics*

{AI95-00285-01} The library package Wide\_Wide\_Text\_IO.Text\_Streams has the following declaration: 2/2

```
with Ada.Streams;
package Ada.Wide_Wide_Text_IO.Text_Streams is
 type Stream_Access is access all Streams.Root_Stream_Type'Class;
 function Stream (File : in File_Type) return Stream_Access;
end Ada.Wide_Wide_Text_IO.Text_Streams; 3/2 4/2
```

{AI95-00285-01} The Stream function has the same effect as the corresponding function in Streams.Stream\_IO. 5/2

5.a/2 {AI95-00285-01} Package Wide\_Wide\_Text\_IO.Text\_Streams is new.

## A.13 Exceptions in Input-Output

1 The package IO\_Exceptions defines the exceptions needed by the predefined input-output packages.

### Static Semantics

2 The library package IO\_Exceptions has the following declaration:

```
3 package Ada.IO_Exceptions is
4 pragma Pure(IO_Exceptions);
5 Status_Error : exception;
6 Mode_Error : exception;
7 Name_Error : exception;
8 Use_Error : exception;
9 Device_Error : exception;
10 End_Error : exception;
11 Data_Error : exception;
12 Layout_Error : exception;
13 end Ada.IO_Exceptions;
```

6 If more than one error condition exists, the corresponding exception that appears earliest in the following list is the one that is propagated.

7 The exception Status\_Error is propagated by an attempt to operate upon a file that is not open, and by an attempt to open a file that is already open.

8 The exception Mode\_Error is propagated by an attempt to read from, or test for the end of, a file whose current mode is Out\_File or Append\_File, and also by an attempt to write to a file whose current mode is In\_File. In the case of Text\_IO, the exception Mode\_Error is also propagated by specifying a file whose current mode is Out\_File or Append\_File in a call of Set\_Input, Skip\_Line, End\_Of\_Line, Skip\_Page, or End\_Of\_Page; and by specifying a file whose current mode is In\_File in a call of Set\_Output, Set\_Line\_Length, Set\_Page\_Length, Line\_Length, Page\_Length, New\_Line, or New\_Page.

9 The exception Name\_Error is propagated by a call of Create or Open if the string given for the parameter Name does not allow the identification of an external file. For example, this exception is propagated if the string is improper, or, alternatively, if either none or more than one external file corresponds to the string.

10 The exception Use\_Error is propagated if an operation is attempted that is not possible for reasons that depend on characteristics of the external file. For example, this exception is propagated by the procedure Create, among other circumstances, if the given mode is Out\_File but the form specifies an input only device, if the parameter Form specifies invalid access rights, or if an external file with the given name already exists and overwriting is not allowed.

11 The exception Device\_Error is propagated if an input-output operation cannot be completed because of a malfunction of the underlying system.

12 The exception End\_Error is propagated by an attempt to skip (read past) the end of a file.

13 The exception Data\_Error can be propagated by the procedure Read (or by the Read attribute) if the element read cannot be interpreted as a value of the required subtype. This exception is also propagated by a procedure Get (defined in the package Text\_IO) if the input character sequence fails to satisfy the required syntax, or if the value input does not belong to the range of the required subtype.

14 The exception Layout\_Error is propagated (in text input-output) by Col, Line, or Page if the value returned exceeds Count'Last. The exception Layout\_Error is also propagated on output by an attempt to

set column or line numbers in excess of specified maximum line or page lengths, respectively (excluding the unbounded cases). It is also propagated by an attempt to Put too many characters to a string.

{AI05-0262-1} These exceptions are also propagated by various other language-defined packages and operations, see the definition of those entities for other reasons that these exceptions are propagated. 14.1/3

**Reason:** {AI05-0299-1} This subclause is based in Ada 95. Later versions of Ada (starting with Technical Corrigendum 1) have added a number of additional places and reasons that cause these exceptions. In particular, TC1 says that stream attributes need to raise End\_Error in some circumstances; Amendment 1 adds Ada.Directories and a number of new places and reasons that Name\_Error and Use\_Error are raised. There are more. We don't want to try to update this text (or even this note!) for every possible reason and place that might raise one of these exceptions, so we add this blanket statement. 14.a/3

#### *Documentation Requirements*

The implementation shall document the conditions under which Name\_Error, Use\_Error and Device\_Error are propagated. 15

**Documentation Requirement:** The conditions under which Io\_Exceptions.Name\_Error, Io\_Exceptions.Use\_Error, and Io\_Exceptions.Device\_Error are propagated. 15.a/2

#### *Implementation Permissions*

If the associated check is too complex, an implementation need not propagate Data\_Error as part of a procedure Read (or the Read attribute) if the value read cannot be interpreted as a value of the required subtype. 16

**Ramification:** An example where the implementation may choose not to perform the check is an enumeration type with a representation clause with “holes” in the range of internal codes. 16.a

#### *Erroneous Execution*

[If the element read by the procedure Read (or by the Read attribute) cannot be interpreted as a value of the required subtype, but this is not detected and Data\_Error is not propagated, then the resulting value can be abnormal, and subsequent references to the value can lead to erroneous execution, as explained in 13.9.1. ] 17

## A.14 File Sharing

#### *Dynamic Semantics*

It is not specified by the language whether the same external file can be associated with more than one file object. If such sharing is supported by the implementation, the following effects are defined: 1

- Operations on one text file object do not affect the column, line, and page numbers of any other file object. 2
- *This paragraph was deleted.* {8652/0057} {AI95-00050-01} 3/1
- For direct and stream files, the current index is a property of each file object; an operation on one file object does not affect the current index of any other file object. 4
- For direct and stream files, the current size of the file is a property of the external file. 5

All other effects are identical. 6

#### *Wording Changes from Ada 95*

{8652/0057} {AI95-00050-01} **Corrigendum:** Removed the incorrect statement that the external files associated with the standard input, standard output, and standard error files are distinct. 6.a/2

## A.15 The Package Command\_Line

1 The package `Command_Line` allows a program to obtain the values of its arguments and to set the exit status code to be returned on normal termination.

1.a/2 **Implementation defined:** The meaning of `Argument_Count`, `Argument`, and `Command_Name` for package `Command_Line`. The bounds of type `Command_Line.Exit_Status`.

### *Static Semantics*

2 The library package `Ada.Command_Line` has the following declaration:

```
3 package Ada.Command_Line is
4 pragma Preelaborate(Command_Line);
5 function Argument_Count return Natural;
6 function Argument (Number : in Positive) return String;
7 function Command_Name return String;
8 type Exit_Status is implementation-defined integer type;
9 Success : constant Exit_Status;
10 Failure : constant Exit_Status;
11 procedure Set_Exit_Status (Code : in Exit_Status);
12 private
13 ... -- not specified by the language
14 end Ada.Command_Line;
```

```
11 function Argument_Count return Natural;
```

12/3 {AI05-0264-1} If the external execution environment supports passing arguments to a program, then `Argument_Count` returns the number of arguments passed to the program invoking the function. Otherwise, it returns 0. The meaning of “number of arguments” is implementation defined.

```
13 function Argument (Number : in Positive) return String;
```

14 If the external execution environment supports passing arguments to a program, then `Argument` returns an implementation-defined value corresponding to the argument at relative position `Number`. If `Number` is outside the range `1..Argument_Count`, then `Constraint_Error` is propagated.

14.a **Ramification:** If the external execution environment does not support passing arguments to a program, then `Argument(N)` for any `N` will raise `Constraint_Error`, since `Argument_Count` is 0.

```
15 function Command_Name return String;
```

16/3 {AI05-0264-1} If the external execution environment supports passing arguments to a program, then `Command_Name` returns an implementation-defined value corresponding to the name of the command invoking the program; otherwise, `Command_Name` returns the null string.

```
16.1/1 type Exit_Status is implementation-defined integer type;
```

17 The type `Exit_Status` represents the range of exit status values supported by the external execution environment. The constants `Success` and `Failure` correspond to success and failure, respectively.

```
18 procedure Set_Exit_Status (Code : in Exit_Status);
```

19 If the external execution environment supports returning an exit status from a program, then `Set_Exit_Status` sets `Code` as the status. Normal termination of a program returns as the exit status the value most recently set by `Set_Exit_Status`, or, if no such value has been set, then the value

Success. If a program terminates abnormally, the status set by `Set_Exit_Status` is ignored, and an implementation-defined exit status value is set.

If the external execution environment does not support returning an exit value from a program, then `Set_Exit_Status` does nothing. 20

*Implementation Permissions*

An alternative declaration is allowed for package `Command_Line` if different functionality is appropriate for the external execution environment. 21

NOTES

40 `Argument_Count`, `Argument`, and `Command_Name` correspond to the C language's `argc`, `argv[n]` (for  $n > 0$ ) and `argv[0]`, respectively. 22

**To be honest:** The correspondence of `Argument_Count` to `argc` is not direct — `argc` would be one more than `Argument_Count`, since the `argc` count includes the command name, whereas `Argument_Count` does not. 22.a

*Extensions to Ada 83*

{*AI05-0299-1*} This subclause is new in Ada 95. 22.b/3

## A.16 The Package Directories

{*AI95-00248-01*} The package `Directories` provides operations for manipulating files and directories, and their names. 1/2

**Discussion:** {*AI05-0299-1*} The notes for this subclause contain the expected interpretations of some of the operations on various target systems. “Unix” refers to the UNIX® operating system, and in most cases also covers Unix-like systems such as Linux and POSIX. “Windows®” refers to the Microsoft® Windows® 2000 operating system and usually also covers most other versions that use the Win32 API. 1.a/3

*Static Semantics*

{*AI95-00248-01*} The library package `Directories` has the following declaration: 2/2

```

with Ada.IO_Exceptions;
with Ada.Calendar;
package Ada.Directories is
 -- Directory and file operations:
 function Current_Directory return String;
 procedure Set_Directory (Directory : in String);
 procedure Create_Directory (New_Directory : in String;
 Form : in String := "");
 procedure Delete_Directory (Directory : in String);
 procedure Create_Path (New_Directory : in String;
 Form : in String := "");
 procedure Delete_Tree (Directory : in String);
 procedure Delete_File (Name : in String);
 procedure Rename (Old_Name, New_Name : in String);
 procedure Copy_File (Source_Name,
 Target_Name : in String;
 Form : in String := "");
 -- File and directory name operations:
 function Full_Name (Name : in String) return String;
 function Simple_Name (Name : in String) return String;
 function Containing_Directory (Name : in String) return String;
 function Extension (Name : in String) return String;

```

```

19/2 function Base_Name (Name : in String) return String;
20/2 function Compose (Containing_Directory : in String := "";
 Name : in String;
 Extension : in String := "") return String;
20.1/3 {AI05-0049-1} type Name_Case_Kind is
 (Unknown, Case_Sensitive, Case_Insensitive, Case_Preserving);
20.2/3 {AI05-0049-1} function Name_Case_Equivalence (Name : in String) return
Name_Case_Kind;
21/2 -- File and directory queries:
22/2 type File_Kind is (Directory, Ordinary_File, Special_File);
23/2 type File_Size is range 0 .. implementation-defined;
24/2 function Exists (Name : in String) return Boolean;
25/2 function Kind (Name : in String) return File_Kind;
26/2 function Size (Name : in String) return File_Size;
27/2 function Modification_Time (Name : in String) return Ada.Calendar.Time;
28/2 -- Directory searching:
29/2 type Directory_Entry_Type is limited private;
30/2 type Filter_Type is array (File_Kind) of Boolean;
31/2 type Search_Type is limited private;
32/2 procedure Start_Search (Search : in out Search_Type;
 Directory : in String;
 Pattern : in String;
 Filter : in Filter_Type := (others => True));
33/2 procedure End_Search (Search : in out Search_Type);
34/2 function More_Entries (Search : in Search_Type) return Boolean;
35/2 procedure Get_Next_Entry (Search : in out Search_Type;
 Directory_Entry : out Directory_Entry_Type);
36/2 procedure Search (
 Directory : in String;
 Pattern : in String;
 Filter : in Filter_Type := (others => True);
 Process : not null access procedure (
 Directory_Entry : in Directory_Entry_Type));
37/2 -- Operations on Directory Entries:
38/2 function Simple_Name (Directory_Entry : in Directory_Entry_Type)
 return String;
39/2 function Full_Name (Directory_Entry : in Directory_Entry_Type)
 return String;
40/2 function Kind (Directory_Entry : in Directory_Entry_Type)
 return File_Kind;
41/2 function Size (Directory_Entry : in Directory_Entry_Type)
 return File_Size;
42/2 function Modification_Time (Directory_Entry : in Directory_Entry_Type)
 return Ada.Calendar.Time;
43/2 Status_Error : exception renames Ada.IO_Exceptions.Status_Error;
 Name_Error : exception renames Ada.IO_Exceptions.Name_Error;
 Use_Error : exception renames Ada.IO_Exceptions.Use_Error;
 Device_Error : exception renames Ada.IO_Exceptions.Device_Error;
44/3 {AI05-0092-1} private
 ... -- not specified by the language
end Ada.Directories;

```

- {AI95-00248-01} External files may be classified as directories, special files, or ordinary files. A *directory* is an external file that is a container for files on the target system. A *special file* is an external file that cannot be created or read by a predefined Ada input-output package. External files that are not special files or directories are called *ordinary files*. 45/2
- Ramification:** A directory is an external file, although it may not have a name on some targets. A directory is not a special file, as it can be created and read by Directories. 45.a/2
- Discussion:** Devices and soft links are examples of special files on Windows® and Unix. 45.b/2
- Even if an implementation provides a package to create and read soft links, such links are still special files. 45.c/2
- {AI95-00248-01} A *file name* is a string identifying an external file. Similarly, a *directory name* is a string identifying a directory. The interpretation of file names and directory names is implementation-defined. 46/2
- Implementation defined:** The interpretation of file names and directory names. 46.a/2
- {AI95-00248-01} The *full name* of an external file is a full specification of the name of the file. If the external environment allows alternative specifications of the name (for example, abbreviations), the full name should not use such alternatives. A full name typically will include the names of all of the directories that contain the item. The *simple name* of an external file is the name of the item, not including any containing directory names. Unless otherwise specified, a file name or directory name parameter in a call to a predefined Ada input-output subprogram can be a full name, a simple name, or any other form of name supported by the implementation. 47/2
- Discussion:** The full name on Unix is a complete path to the root. For Windows®, the full name includes a complete path, as well as a disk name ("C:") or network share name. For both systems, the simple name is the part of the name following the last '/' (or '\' for Windows®). For example, in the name "/usr/randy/ada-directories.ads", "ada-directories.ads" is the simple name. 47.a/2
- Ramification:** It is possible for a file or directory name to be neither a full name nor a simple name. For instance, the Unix name "../parent/myfile" is neither a full name nor a simple name. 47.b/2
- {AI95-00248-01} The *default directory* is the directory that is used if a directory or file name is not a full name (that is, when the name does not fully identify all of the containing directories). 48/2
- Discussion:** The default directory is the one maintained by the familiar "cd" command on Unix and Windows®. Note that Windows® maintains separate default directories for each disk drive; implementations should use the natural implementation. 48.a/2
- {AI95-00248-01} A *directory entry* is a single item in a directory, identifying a single external file (including directories and special files). 49/2
- {AI95-00248-01} For each function that returns a string, the lower bound of the returned value is 1. 50/2
- {AI95-00248-01} The following file and directory operations are provided: 51/2
- function** Current\_Directory **return** String; 52/2
- Returns the full directory name for the current default directory. The name returned shall be suitable for a future call to Set\_Directory. The exception Use\_Error is propagated if a default directory is not supported by the external environment. 53/2
- procedure** Set\_Directory (Directory : **in** String); 54/2
- Sets the current default directory. The exception Name\_Error is propagated if the string given as Directory does not identify an existing directory. The exception Use\_Error is propagated if the external environment does not support making Directory (in the absence of Name\_Error) a default directory. 55/2

56/2 **procedure** Create\_Directory (New\_Directory : in String;  
Form : in String := "");

57/2 Creates a directory with name New\_Directory. The Form parameter can be used to give system-dependent characteristics of the directory; the interpretation of the Form parameter is implementation-defined. A null string for Form specifies the use of the default options of the implementation of the new directory. The exception Name\_Error is propagated if the string given as New\_Directory does not allow the identification of a directory. The exception Use\_Error is propagated if the external environment does not support the creation of a directory with the given name (in the absence of Name\_Error) and form.

58/2 **procedure** Delete\_Directory (Directory : in String);

59/3 {AI05-0231-1} Deletes an existing empty directory with name Directory. The exception Name\_Error is propagated if the string given as Directory does not identify an existing directory. The exception Use\_Error is propagated if the directory is not empty or the external environment does not support the deletion of the directory with the given name (in the absence of Name\_Error).

60/2 **procedure** Create\_Path (New\_Directory : in String;  
Form : in String := "");

61/3 {AI05-0271-1} Creates zero or more directories with name New\_Directory. Each nonexistent directory named by New\_Directory is created.[ For example, on a typical Unix system, Create\_Path ("/usr/me/my"); would create directory "me" in directory "usr", then create directory "my" in directory "me".] The Form parameter can be used to give system-dependent characteristics of the directory; the interpretation of the Form parameter is implementation-defined. A null string for Form specifies the use of the default options of the implementation of the new directory. The exception Name\_Error is propagated if the string given as New\_Directory does not allow the identification of any directory. The exception Use\_Error is propagated if the external environment does not support the creation of any directories with the given name (in the absence of Name\_Error) and form. If Use\_Error is propagated, it is unspecified whether a portion of the directory path is created.

62/2 **procedure** Delete\_Tree (Directory : in String);

63/2 Deletes an existing directory with name Directory. The directory and all of its contents (possibly including other directories) are deleted. The exception Name\_Error is propagated if the string given as Directory does not identify an existing directory. The exception Use\_Error is propagated if the external environment does not support the deletion of the directory or some portion of its contents with the given name (in the absence of Name\_Error). If Use\_Error is propagated, it is unspecified whether a portion of the contents of the directory is deleted.

64/2 **procedure** Delete\_File (Name : in String);

65/2 Deletes an existing ordinary or special file with name Name. The exception Name\_Error is propagated if the string given as Name does not identify an existing ordinary or special external file. The exception Use\_Error is propagated if the external environment does not support the deletion of the file with the given name (in the absence of Name\_Error).

66/2 **procedure** Rename (Old\_Name, New\_Name : in String);

67/3 {AI05-0231-1} Renames an existing external file (including directories) with name Old\_Name to New\_Name. The exception Name\_Error is propagated if the string given as Old\_Name does not identify an existing external file or if the string given as New\_Name does not allow the identification of an external file. The exception Use\_Error is propagated if the external environment does not support the renaming of the file with the given name (in the absence of

Name\_Error). In particular, Use\_Error is propagated if a file or directory already exists with name New\_Name.

**Implementation Note:** This operation is expected to work within a single directory, and implementers are encouraged to support it across directories on a single device. Copying files from one device to another is discouraged (that's what Copy\_File is for). However, there is no requirement to detect file copying by the target system. If the target system has an API that gives that for “free”, it can be used. For Windows®, for instance, MoveFile can be used to implement Rename. 67.a/2

```
{AI05-0092-1} procedure Copy_File (Source_Name,
 Target_Name : in String;
 Form : in String := ""); 68/3
```

{AI05-0271-1} Copies the contents of the existing external file with name Source\_Name to an external file with name Target\_Name. The resulting external file is a duplicate of the source external file. The Form parameter can be used to give system-dependent characteristics of the resulting external file; the interpretation of the Form parameter is implementation-defined. Exception Name\_Error is propagated if the string given as Source\_Name does not identify an existing external ordinary or special file, or if the string given as Target\_Name does not allow the identification of an external file. The exception Use\_Error is propagated if the external environment does not support creating the file with the name given by Target\_Name and form given by Form, or copying of the file with the name given by Source\_Name (in the absence of Name\_Error). If Use\_Error is propagated, it is unspecified whether a portion of the file is copied. 69/3

**Ramification:** Name\_Error is always raised if Source\_Name identifies a directory. It is up to the implementation whether special files can be copied, or if Use\_Error will be raised. 69.a/2

{AI95-00248-01} The following file and directory name operations are provided: 70/2

```
function Full_Name (Name : in String) return String; 71/2
```

Returns the full name corresponding to the file name specified by Name. The exception Name\_Error is propagated if the string given as Name does not allow the identification of an external file (including directories and special files). 72/2

**Discussion:** Full name means that no abbreviations are used in the returned name, and that it is a full specification of the name. Thus, for Unix and Windows®, the result should be a full path that does not contain any "." or ".." directories. Typically, the default directory is used to fill in any missing information. 72.a/2

```
function Simple_Name (Name : in String) return String; 73/2
```

Returns the simple name portion of the file name specified by Name. The exception Name\_Error is propagated if the string given as Name does not allow the identification of an external file (including directories and special files). 74/2

```
function Containing_Directory (Name : in String) return String; 75/2
```

Returns the name of the containing directory of the external file (including directories) identified by Name. (If more than one directory can contain Name, the directory name returned is implementation-defined.) The exception Name\_Error is propagated if the string given as Name does not allow the identification of an external file. The exception Use\_Error is propagated if the external file does not have a containing directory. 76/2

**Discussion:** This is purely a string manipulation function. If Name is not given as a full name, the containing directory probably won't be one, either. For example, if Containing\_Directory (".\AARM\RM-A-8") is called on Windows®, the result should be ".\AARM". If there is no path at all on the name, the result should be "." (which represents the current directory). Use Full\_Name on the result of Containing\_Directory if the full name is needed. 76.a/2

```
function Extension (Name : in String) return String; 77/2
```

Returns the extension name corresponding to Name. The extension name is a portion of a simple name (not including any separator characters), typically used to identify the file class. If the 78/2

external environment does not have extension names, then the null string is returned. The exception `Name_Error` is propagated if the string given as `Name` does not allow the identification of an external file.

78.a/2 **Discussion:** For Unix and Windows®, the extension is the portion of the simple name following the rightmost period. For example, in the simple name "RM-A-8.html", the extension is "html".

79/2 **function** Base\_Name (Name : **in** String) **return** String;

80/2 Returns the base name corresponding to `Name`. The base name is the remainder of a simple name after removing any extension and extension separators. The exception `Name_Error` is propagated if the string given as `Name` does not allow the identification of an external file (including directories and special files).

80.a/2 **Discussion:** For Unix and Windows®, the base name is the portion of the simple name preceding the rightmost period (except for the special directory names "." and "..", whose `Base_Name` is "." and ".."). For example, in the simple name "RM-A-8.html", the base name is "RM-A-8".

81/2 **function** Compose (Containing\_Directory : **in** String := "";  
Name : **in** String;  
Extension : **in** String := "") **return** String;

82/3 {AI05-0264-1} Returns the name of the external file with the specified `Containing_Directory`, `Name`, and `Extension`. If `Extension` is the null string, then `Name` is interpreted as a simple name; otherwise, `Name` is interpreted as a base name. The exception `Name_Error` is propagated if the string given as `Containing_Directory` is not null and does not allow the identification of a directory, or if the string given as `Extension` is not null and is not a possible extension, or if the string given as `Name` is not a possible simple name (if `Extension` is null) or base name (if `Extension` is nonnull).

82.a/2 **Ramification:** The above definition implies that if the `Extension` is null, for Unix and Windows® no '.' is added to `Name`.

82.b/2 **Discussion:** If `Name` is null, `Name_Error` should be raised, as nothing is not a possible simple name or base name.

82.c/2 Generally, `Compose(Containing_Directory(F), Base_Name(F), Extension(F)) = F`. However, this is not true on Unix or Windows® for file names that end with a '.'; `Compose(Base_Name("Foocy."), Extension("Foocy.")) = "Foocy"`. This is not a problem for Windows®, as the names have the same meaning with or without the '.', but these are different names for Unix. Thus, care needs to be taken on Unix; if `Extension` is null, `Base_Name` should be avoided. (That's not usually a problem with file names generated by a program.)

82.1/3 {AI05-0049-1} **function** Name\_Case\_Equivalence (Name : **in** String) **return**  
Name\_Case\_Kind;

82.2/3 {AI05-0049-1} {AI05-0248-1} Returns the file name equivalence rule for the directory containing `Name`. Raises `Name_Error` if `Name` is not a full name. Returns `Case_Sensitive` if file names that differ only in the case of letters are considered different names. If file names that differ only in the case of letters are considered the same name, then `Case_Preserving` is returned if names have the case of the file name used when a file is created; and `Case_Insensitive` is returned otherwise. Returns `Unknown` if the file name equivalence is not known.

82.c.1/3 **Implementation Note:** Unix, Linux, and their relatives are Case Sensitive systems. Microsoft® Windows® is a Case\_Preserving system (unless the rarely used POSIX mode is used). Ancient systems like CP/M and early MS-DOS were Case\_Insensitive systems (file names were always in UPPER CASE). `Unknown` is provided in case it is impossible to tell (such as could be the case for network files).

83/2 {AI95-00248-01} The following file and directory queries and types are provided:

84/2 **type** File\_Kind **is** (Directory, Ordinary\_File, Special\_File);

85/2 The type `File_Kind` represents the kind of file represented by an external file or directory.

86/2 **type** File\_Size **is range** 0 .. *implementation-defined*;

87/2 The type `File_Size` represents the size of an external file.

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |        |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|

| Returns the kind of external file represented by Name. The exception Name_Error is propagated if the string given as Name does not allow the identification of an existing external file.                                                                                                                                                                                                                                                                                                               | 91/2   |
| <b>function</b> Size (Name : in String) <b>return</b> File_Size;                                                                                                                                                                                                                                                                                                                                                                                                                                        | 92/2   |
| Returns the size of the external file represented by Name. The size of an external file is the number of stream elements contained in the file. If the external file is not an ordinary file, the result is implementation-defined. The exception Name_Error is propagated if the string given as Name does not allow the identification of an existing external file. The exception Constraint_Error is propagated if the file size is not a value of type File_Size.                                  | 93/2   |
| <b>Implementation defined:</b> The result for Directories.Size for a directory or special file                                                                                                                                                                                                                                                                                                                                                                                                          | 93.a/2 |
| <b>Discussion:</b> We allow raising Constraint_Error, so that an implementation for a system with 64-bit file sizes does not need to support full numerics on 64-bit integers just to implement this package. Of course, if 64-bit integers are available on such a system, they should be used when defining type File_Size.                                                                                                                                                                           | 93.b/2 |
| <b>function</b> Modification_Time (Name : in String) <b>return</b> Ada.Calendar.Time;                                                                                                                                                                                                                                                                                                                                                                                                                   | 94/2   |
| Returns the time that the external file represented by Name was most recently modified. If the external file is not an ordinary file, the result is implementation-defined. The exception Name_Error is propagated if the string given as Name does not allow the identification of an existing external file. The exception Use_Error is propagated if the external environment does not support reading the modification time of the file with the name given by Name (in the absence of Name_Error). | 95/2   |
| <b>Implementation defined:</b> The result for Directories.Modification_Time for a directory or special file.                                                                                                                                                                                                                                                                                                                                                                                            | 95.a/2 |

| The type Directory_Entry_Type represents a single item in a directory. These items can only be created by the Get_Next_Entry procedure in this package. Information about the item can be obtained from the functions declared in this package. A default-initialized object of this type is invalid; objects returned from Get_Next_Entry are valid.                                                                                                                                                   | 98/2   |
| <b>type</b> Filter_Type <b>is array</b> (File_Kind) <b>of</b> Boolean;                                                                                                                                                                                                                                                                                                                                                                                                                                  | 99/2   |
| The type Filter_Type specifies which directory entries are provided from a search operation. If the Directory component is True, directory entries representing directories are provided. If the Ordinary_File component is True, directory entries representing ordinary files are provided. If the Special_File component is True, directory entries representing special files are provided.                                                                                                         | 100/2  |
| <b>type</b> Search_Type <b>is limited private</b> ;                                                                                                                                                                                                                                                                                                                                                                                                                                                     | 101/2  |
| The type Search_Type contains the state of a directory search. A default-initialized Search_Type object has no entries available (function More_Entries returns False). Type Search_Type needs finalization (see 7.6).                                                                                                                                                                                                                                                                                  | 102/2  |

- 103/2     **procedure** Start\_Search (Search     : **in out** Search\_Type;  
                                   Directory : **in** String;  
                                   Pattern   : **in** String;  
                                   Filter    : **in** Filter\_Type := (**others =>** True));
- 104/3     {AI05-0092-1} {AI05-0262-1} Starts a search in the directory named by Directory for entries matching Pattern and Filter. Pattern represents a pattern for matching file names. If Pattern is the null string, all items in the directory are matched; otherwise, the interpretation of Pattern is implementation-defined. Only items that match Filter will be returned. After a successful call on Start\_Search, the object Search may have entries available, but it may have no entries available if no files or directories match Pattern and Filter. The exception Name\_Error is propagated if the string given by Directory does not identify an existing directory, or if Pattern does not allow the identification of any possible external file or directory. The exception Use\_Error is propagated if the external environment does not support the searching of the directory with the given name (in the absence of Name\_Error). When Start\_Search propagates Name\_Error or Use\_Error, the object Search will have no entries available.
- 104.a/2     **Implementation defined:** The interpretation of a nonnull search pattern in Directories.
- 105/2     **procedure** End\_Search (Search : **in out** Search\_Type);
- 106/2     Ends the search represented by Search. After a successful call on End\_Search, the object Search will have no entries available.
- 106.a/2     **Ramification:** The only way that a call to End\_Search could be unsuccessful if Device\_Error (see A.13) is raised because of an underlying failure (or bug).
- 107/2     **function** More\_Entries (Search : **in** Search\_Type) **return** Boolean;
- 108/2     Returns True if more entries are available to be returned by a call to Get\_Next\_Entry for the specified search object, and False otherwise.
- 109/2     **procedure** Get\_Next\_Entry (Search : **in out** Search\_Type;  
                                   Directory\_Entry : **out** Directory\_Entry\_Type);
- 110/3     {AI05-0262-1} Returns the next Directory\_Entry for the search described by Search that matches the pattern and filter. If no further matches are available, Status\_Error is raised. It is implementation-defined as to whether the results returned by this subprogram are altered if the contents of the directory are altered while the Search object is valid (for example, by another program). The exception Use\_Error is propagated if the external environment does not support continued searching of the directory represented by Search.
- 110.a/2     **Implementation defined:** The results of a Directories search if the contents of the directory are altered while a search is in progress.
- 111/2     **procedure** Search (  
           Directory : **in** String;  
           Pattern   : **in** String;  
           Filter    : **in** Filter\_Type := (**others =>** True);  
           Process   : **not null access procedure** (  
                     Directory\_Entry : **in** Directory\_Entry\_Type));
- 112/3     {AI05-0092-1} {AI05-0262-1} Searches in the directory named by Directory for entries matching Pattern and Filter. The subprogram designated by Process is called with each matching entry in turn. Pattern represents a pattern for matching file names. If Pattern is the null string, all items in the directory are matched; otherwise, the interpretation of Pattern is implementation-defined. Only items that match Filter will be returned. The exception Name\_Error is propagated if the string given by Directory does not identify an existing directory, or if Pattern does not allow the identification of any possible external file or directory. The exception Use\_Error is propagated if the external environment does not support the searching of the directory with the given name (in the absence of Name\_Error).

- Discussion:** “In turn” means that the calls to the subprogram designated by `Process` are not made in parallel; they can be made in any order but must be in sequence. 112.a/2
- function** `Simple_Name` (`Directory_Entry` : **in** `Directory_Entry_Type`) 113/2  
     **return** `String`;
- Returns the simple external name of the external file (including directories) represented by `Directory_Entry`. The format of the name returned is implementation-defined. The exception `Status_Error` is propagated if `Directory_Entry` is invalid. 114/2
- function** `Full_Name` (`Directory_Entry` : **in** `Directory_Entry_Type`) 115/2  
     **return** `String`;
- Returns the full external name of the external file (including directories) represented by `Directory_Entry`. The format of the name returned is implementation-defined. The exception `Status_Error` is propagated if `Directory_Entry` is invalid. 116/2
- function** `Kind` (`Directory_Entry` : **in** `Directory_Entry_Type`) 117/2  
     **return** `File_Kind`;
- Returns the kind of external file represented by `Directory_Entry`. The exception `Status_Error` is propagated if `Directory_Entry` is invalid. 118/2
- function** `Size` (`Directory_Entry` : **in** `Directory_Entry_Type`) 119/2  
     **return** `File_Size`;
- Returns the size of the external file represented by `Directory_Entry`. The size of an external file is the number of stream elements contained in the file. If the external file represented by `Directory_Entry` is not an ordinary file, the result is implementation-defined. The exception `Status_Error` is propagated if `Directory_Entry` is invalid. The exception `Constraint_Error` is propagated if the file size is not a value of type `File_Size`. 120/2
- function** `Modification_Time` (`Directory_Entry` : **in** `Directory_Entry_Type`) 121/2  
     **return** `Ada.Calendar.Time`;
- Returns the time that the external file represented by `Directory_Entry` was most recently modified. If the external file represented by `Directory_Entry` is not an ordinary file, the result is implementation-defined. The exception `Status_Error` is propagated if `Directory_Entry` is invalid. The exception `Use_Error` is propagated if the external environment does not support reading the modification time of the file represented by `Directory_Entry`. 122/2

#### *Implementation Requirements*

For `Copy_File`, if `Source_Name` identifies an existing external ordinary file created by a predefined Ada input-output package, and `Target_Name` and `Form` can be used in the `Create` operation of that input-output package with mode `Out_File` without raising an exception, then `Copy_File` shall not propagate `Use_Error`. 123/2

**Discussion:** This means that `Copy_File` will copy any file that the Ada programmer could copy (by writing some possibly complicated Ada code). 123.a/2

#### *Implementation Advice*

If other information about a file (such as the owner or creation date) is available in a directory entry, the implementation should provide functions in a child package `Directories.Information` to retrieve it. 124/2

**Implementation Advice:** Package `Directories.Information` should be provided to retrieve other information about a file. 124.a/2

**Implementation Note:** For Windows®, `Directories.Information` should contain at least the following routines: 124.b/2

```

package Ada.Directories.Information is 124.c/2
 -- System-specific directory information.
 -- Version for the Microsoft® Windows® operating system.

```

```

124.d/2 function Creation_Time (Name : in String) return Ada.Calendar.Time;
124.e/2 function Last_Access_Time (Name : in String) return Ada.Calendar.Time;
124.f/2 function Is_Read_Only (Name : in String) return Boolean;
124.g/2 function Needs_Archiving (Name : in String) return Boolean;
 -- This generally means that the file needs to be backed up.
 -- The flag is only cleared by backup programs.
124.h/2 function Is_Compressed (Name : in String) return Boolean;
124.i/2 function Is_Encrypted (Name : in String) return Boolean;
124.j/2 function Is_Hidden (Name : in String) return Boolean;
124.k/2 function Is_System (Name : in String) return Boolean;
124.l/2 function Is_Offline (Name : in String) return Boolean;
124.m/2 function Is_Temporary (Name : in String) return Boolean;
124.n/2 function Is_Sparse (Name : in String) return Boolean;
124.o/2 function Is_Not_Indexed (Name : in String) return Boolean;
124.p/2 function Creation_Time (Directory_Entry : in Directory_Entry_Type)
 return Ada.Calendar.Time;
124.q/2 function Last_Access_Time (Directory_Entry : in Directory_Entry_Type)
 return Ada.Calendar.Time;
124.r/2 function Is_Read_Only (Directory_Entry : in Directory_Entry_Type) return Boolean;
124.s/2 function Needs_Archiving (Directory_Entry : in Directory_Entry_Type) return
Boolean;
 -- This generally means that the file needs to be backed up.
 -- The flag is only cleared by backup programs.
124.t/2 function Is_Compressed (Directory_Entry : in Directory_Entry_Type) return Boolean;
124.u/2 function Is_Encrypted (Directory_Entry : in Directory_Entry_Type) return Boolean;
124.v/2 function Is_Hidden (Directory_Entry : in Directory_Entry_Type) return Boolean;
124.w/2 function Is_System (Directory_Entry : in Directory_Entry_Type) return Boolean;
124.x/2 function Is_Offline (Directory_Entry : in Directory_Entry_Type) return Boolean;
124.y/2 function Is_Temporary (Directory_Entry : in Directory_Entry_Type) return Boolean;
124.z/2 function Is_Sparse (Directory_Entry : in Directory_Entry_Type) return Boolean;
124.aa/2 function Is_Not_Indexed (Directory_Entry : in Directory_Entry_Type) return
Boolean;
124.bb/2 -- Additional implementation-defined subprograms allowed here.
end Ada.Directories.Information;

124.cc/2 For Unix-like systems (Unix, POSIX, Linux, etc.), Directories.Information should contain at least the following
routines:
124.dd/2 package Ada.Directories.Information is
 -- System-specific directory information.
 -- Unix and similar systems version.
124.ee/2 function Last_Access_Time (Name : in String) return Ada.Calendar.Time;
124.ff/2 function Last_Status_Change_Time (Name : in String) return Ada.Calendar.Time;
124.gg/2 type Permission is
 (Others_Execute, Others_Write, Others_Read,
 Group_Execute, Group_Write, Group_Read,
 Owner_Execute, Owner_Write, Owner_Read,
 Set_Group_ID, Set_User_ID);
124.hh/2 type Permission_Set_Type is array (Permission) of Boolean;
124.ii/2 function Permission_Set (Name : in String) return Permission_Set_Type;
124.jj/2 function Owner (Name : in String) return String;
 -- Returns the image of the User_Id. If a definition of User_Id
 -- is available, an implementation-defined version of Owner
 -- returning User_Id should also be defined.
124.kk/3 {AI05-0005-1} function Group (Name : in String) return String;
 -- Returns the image of the Group_Id. If a definition of Group_Id
 -- is available, an implementation-defined version of Group
 -- returning Group_Id should also be defined.
124.ll/2 function Is_Block_Special_File (Name : in String) return Boolean;
124.mm/2 function Is_Character_Special_File (Name : in String) return Boolean;

```

```

function Is_FIFO (Name : in String) return Boolean; 124.nn/2
function Is_Symbolic_Link (Name : in String) return Boolean; 124.oo/2
function Is_Socket (Name : in String) return Boolean; 124.pp/2
function Last_Access_Time (Directory_Entry : in Directory_Entry_Type)
 return Ada.Calendar.Time; 124.qq/2
function Last_Status_Change_Time (Directory_Entry : in Directory_Entry_Type)
 return Ada.Calendar.Time; 124.rr/2
function Permission_Set (Directory_Entry : in Directory_Entry_Type)
 return Permission_Set_Type; 124.ss/2
function Owner (Directory_Entry : in Directory_Entry_Type) return String;
 -- See Owner above. 124.tt/2
function Group (Directory_Entry : in Directory_Entry_Type) return String;
 -- See Group above. 124.uu/2
function Is_Block_Special_File (Directory_Entry : in Directory_Entry_Type)
 return Boolean; 124.vv/2
function Is_Character_Special_File (Directory_Entry : in Directory_Entry_Type)
 return Boolean; 124.wv/2
function Is_FIFO (Directory_Entry : in Directory_Entry_Type) return Boolean;
 return Boolean; 124.xx/2
function Is_Symbolic_Link (Directory_Entry : in Directory_Entry_Type)
 return Boolean; 124.yy/2
function Is_Socket (Directory_Entry : in Directory_Entry_Type) return Boolean;
 -- Additional implementation-defined subprograms allowed here. 124.zz/2
end Ada.Directories.Information; 124.aaa/2

```

We give these definitions to give guidance so that every implementation for a given target is not unnecessarily different. Implementers are encouraged to make packages for other targets as similar to these as possible. 124.bbb/2

{AI05-0231-1} Start\_Search and Search should raise Name\_Error if Pattern is malformed, but not if it could represent a file in the directory but does not actually do so. 125/3

**Implementation Advice:** Directories.Start\_Search and Directories.Search should raise Name\_Error for malformed patterns. 125.a/3

Rename should be supported at least when both New\_Name and Old\_Name are simple names and New\_Name does not identify an existing external file. 126/2

**Implementation Advice:** Directories.Rename should be supported at least when both New\_Name and Old\_Name are simple names and New\_Name does not identify an existing external file. 126.a/2

**Discussion:** “Supported” includes raising an exception if either name is malformed, the file to rename doesn't exist, insufficient permission for the operation exists, or similar problems. But this advice requires implementations to document what they do, and tells implementers that simply raising Use\_Error isn't acceptable. 126.b/2

#### NOTES

41 The operations Containing\_Directory, Full\_Name, Simple\_Name, Base\_Name, Extension, and Compose operate on file names, not external files. The files identified by these operations do not need to exist. Name\_Error is raised only if the file name is malformed and cannot possibly identify a file. Of these operations, only the result of Full\_Name depends on the current default directory; the result of the others depends only on their parameters. 127/2

42 Using access types, values of Search\_Type and Directory\_Entry\_Type can be saved and queried later. However, another task or application can modify or delete the file represented by a Directory\_Entry\_Type value or the directory represented by a Search\_Type value; such a value can only give the information valid at the time it is created. Therefore, long-term storage of these values is not recommended. 128/2

43 If the target system does not support directories inside of directories, then Kind will never return Directory and Containing\_Directory will always raise Use\_Error. 129/2

44 If the target system does not support creation or deletion of directories, then Create\_Directory, Create\_Path, Delete\_Directory, and Delete\_Tree will always propagate Use\_Error. 130/2

45 To move a file or directory to a different location, use Rename. Most target systems will allow renaming of files from one directory to another. If the target file or directory might already exist, it should be deleted first. 131/2

**Discussion:** While Rename is only guaranteed to work for name changes within a single directory, its unlikely that implementers would purposely prevent functionality present in the underlying system from working. To move a file totally portably, it's necessary to handle failure of the Rename and fall back to Copy\_File and Delete: 131.a/2

```

131.b begin
 Rename (Source, Target);
 exception
 when Use_Error =>
 Copy_File (Source, Target);
 Delete (Source);
 end;

```

*Extensions to Ada 95*

131.c/2    *{AI95-00248-01}* Package Ada.Directories is new.

*Inconsistencies With Ada 2005*

131.d/3    *{AI05-0231-1}* **Correction:** Clarified when and which exceptions are raised for Start\_Search, Search, Delete\_Directory, and Rename. If an implementation followed the original incorrect wording, it might raise Use\_Error instead of Name\_Error for Start\_Search and Search, Name\_Error instead of Use\_Error for Rename, and might have deleted a nonempty directory instead of raising Use\_Error for Delete\_Directory. The first two cases are very unlikely to matter in practice, and it unlikely that an implementation would have followed the latter implementation strategy, as it would be more work and would make Delete\_Directory identical to Delete\_Tree (which is obvious nonsense).

*Incompatibilities With Ada 2005*

131.e/3    *{AI05-0049-1}* A new enumeration type Name\_Case\_Kind and a new function Name\_Case\_Equivalence is added to Directories. If Directories is referenced in a use\_clause, and an entity *E* with a defining\_identifier of one of the new entities is defined in a package that is also referenced in a use\_clause, the entity *E* may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur.

*Wording Changes from Ada 2005*

131.f/3    *{AI05-0271-1}* **Correction:** We now explicitly say that the behavior of Create\_Path and Copy\_File is unspecified when Use\_Error is raised. Nothing has changed here, as the behavior was (implicitly) unspecified in the 2007 Amendment.

## A.16.1 The Package Directories.Hierarchical\_File\_Names

1/3    *{AI05-0049-1}* The library package Directories.Hierarchical\_File\_Names is an optional package providing operations for file name construction and decomposition for targets with hierarchical file naming.

*Static Semantics*

2/3    *{AI05-0049-1}* If provided, the library package Directories.Hierarchical\_File\_Names has the following declaration:

```

3/3 package Ada.Directories.Hierarchical_File_Names is
4/3 function Is_Simple_Name (Name : in String) return Boolean;
5/3 function Is_Root_Directory_Name (Name : in String) return Boolean;
6/3 function Is_Parent_Directory_Name (Name : in String) return Boolean;
7/3 function Is_Current_Directory_Name (Name : in String) return Boolean;
8/3 function Is_Full_Name (Name : in String) return Boolean;
9/3 function Is_Relative_Name (Name : in String) return Boolean;
10/3 function Simple_Name (Name : in String) return String
 renames Ada.Directories.Simple_Name;
11/3 function Containing_Directory (Name : in String) return String
 renames Ada.Directories.Containing_Directory;
12/3 function Initial_Directory (Name : in String) return String;
13/3 function Relative_Name (Name : in String) return String;
14/3 function Compose (Directory : in String := "";
 Relative_Name : in String;
 Extension : in String := "") return String;

```

```

end Ada.Directories.Hierarchical_File_Names;
15/3

```

*{AI05-0049-1}* *{AI05-0269-1}* In addition to the operations provided in package Directories.Hierarchical\_File\_Names, the operations in package Directories can be used with hierarchical file names. In particular, functions Full\_Name, Base\_Name, and Extension provide additional capabilities for hierarchical file names. 16/3

```

function Is_Simple_Name (Name : in String) return Boolean;
17/3
 Returns True if Name is a simple name, and returns False otherwise.
18/3
function Is_Root_Directory_Name (Name : in String) return Boolean;
19/3
 Returns True if Name is syntactically a root (a directory that cannot be decomposed further), and
20/3
 returns False otherwise.
Implementation Note: For Unix and Unix-like systems, "/" is the root. For Windows, "C:\" and "\\Computer\Share"
20.a/3
 are roots.
function Is_Parent_Directory_Name (Name : in String) return Boolean;
21/3
 Returns True if Name can be used to indicate symbolically the parent directory of any directory,
22/3
 and returns False otherwise.
Implementation Note: Is_Parent_Directory_Name returns True if and only if Name is ".." for both Unix and
22.a/3
 Windows.
function Is_Current_Directory_Name (Name : in String) return Boolean;
23/3
 Returns True if Name can be used to indicate symbolically the directory itself for any directory,
24/3
 and returns False otherwise.
Implementation Note: Is_Current_Directory_Name returns True if and only if Name is "." for both Unix and
24.a/3
 Windows.
function Is_Full_Name (Name : in String) return Boolean;
25/3
 Returns True if the leftmost directory part of Name is a root, and returns False otherwise.
26/3
function Is_Relative_Name (Name : in String) return Boolean;
27/3
{AI05-0049-1} {AI05-0269-1} Returns True if Name allows the identification of an external file
28/3
 (including directories and special files) but is not a full name, and returns False otherwise.
Ramification: Relative names include simple names as a special case. This function returns False if the syntax of the
28.a/3
 name is incorrect.
function Initial_Directory (Name : in String) return String;
29/3
{AI05-0049-1} {AI05-0248-1} Returns the leftmost directory part in Name. [That is, it returns a
30/3
 root directory name (for a full name), or one of a parent directory name, a current directory name,
 or a simple name (for a relative name).] The exception Name_Error is propagated if the string
 given as Name does not allow the identification of an external file (including directories and
 special files).
function Relative_Name (Name : in String) return String;
31/3
 Returns the entire file name except the Initial_Directory portion. The exception Name_Error is
32/3
 propagated if the string given as Name does not allow the identification of an external file
 (including directories and special files), or if Name has a single part (this includes if any of
 Is_Simple_Name, Is_Root_Directory_Name, Is_Parent_Directory_Name, or
 Is_Current_Directory_Name are True).
Ramification: The result might be a simple name.
32.a/3
function Compose (Directory : in String := "";
 Relative_Name : in String;
 Extension : in String := "") return String;
33/3

```

- 34/3 Returns the name of the external file with the specified Directory, Relative\_Name, and Extension. The exception Name\_Error is propagated if the string given as Directory is not the null string and does not allow the identification of a directory, or if Is\_Relative\_Name (Relative\_Name) is False, or if the string given as Extension is not the null string and is not a possible extension, or if Extension is not the null string and Simple\_Name (Relative\_Name) is not a base name.
- 35/3 The result of Compose is a full name if Is\_Full\_Name (Directory) is True; result is a relative name otherwise.
- 35.a/3 **Ramification:** Name\_Error is raised by Compose if Directory is not the null string, and both Is\_Full\_Name and Is\_Relative\_Name return False.
- 35.b/3 **Discussion:** A common security problem is to include a parent directory name in the middle of a file name; this is often used to navigate outside of an intended root directory. We considered attempting to prevent that case by having Compose detect it and raise an exception. But the extra rules necessary were more confusing than helpful.
- 35.c/3 We can say more about the details of these operations by adopting the notation of a subscript to specify how many path fragments a particular result has. Then, we can abbreviate "Full Name" as "Full" and "Relative Name" as "Rel". In this notation, Unix file name "a/b" is a Rel(2), "../c/d" is a Rel(3), and "/a/b" is a Full(2). Rel(1) is equivalent to a simple name; thus we don't have to describe that separately.
- 35.d/3 In this notation,
- 35.e/3 

```
For N>1,
Containing_Directory(Rel(N)) = Leftmost Rel(N-1),
Containing_Directory(Full(N)) = Leftmost Full(N-1),
Else if N = 1, raise Name_Error.
```
- 35.f/3 Similarly,
- 35.g/3 

```
For N>1,
Relative_Name(Rel(N)) = Rightmost Rel(N-1),
Relative_Name(Full(N)) = Rightmost Full(N-1),
Else if N = 1, raise Name_Error.
```
- 35.h/3 Finally, for Compose (ignoring the extension here):
- 35.i/3 

```
Compose (Directory => Full(N), Relative_Name => Rel(M)) => Full(N+M)
Compose (Directory => Rel(N), Relative_Name => Rel(M)) => Rel(N+M)
Name_Error if Relative_Name is a Full(M).
```
- 35.j/3 We didn't try to write wording to reflect these details of these functions.

*Implementation Advice*

- 36/3 {AI05-0049-1} Directories.Hierarchical\_File\_Names should be provided for systems with hierarchical file naming, and should not be provided on other systems.
- 36.a/3 **Implementation Advice:** Directories.Hierarchical\_File\_Names should be provided for systems with hierarchical file naming, and should not be provided on other systems.
- 36.b/3 **Implementation Note:** This package should be provided when targeting Microsoft® Windows®, Unix, Linux, and most Unix-like systems.

## NOTES

- 37/3 46 {AI05-0049-1} These operations operate on file names, not external files. The files identified by these operations do not need to exist. Name\_Error is raised only as specified or if the file name is malformed and cannot possibly identify a file. The result of these operations depends only on their parameters.
- 38/3 47 {AI05-0049-1} Containing\_Directory raises Use\_Error if Name does not have a containing directory, including when any of Is\_Simple\_Name, Is\_Root\_Directory\_Name, Is\_Parent\_Directory\_Name, or Is\_Current\_Directory\_Name are True.
- 38.a/3 **Ramification:** In particular, the default directory is not used to find the containing directory either when Is\_Parent\_Directory\_Name or Is\_Current\_Directory\_Name is True. As noted above, these functions operate purely on the syntax of the file names and do not attempt to interpret them. If interpretation is needed, Directories.Full\_Name can be to expand any shorthands used before calling Containing\_Directory.

*Extensions to Ada 2005*

- 38.b/3 {AI05-0049-1} Package Ada.Directories.Hierarchical\_File\_Names is new.

## A.17 The Package Environment\_Variables

{AI95-00370-01} The package Environment\_Variables allows a program to read or modify environment variables. Environment variables are name-value pairs, where both the name and value are strings. The definition of what constitutes an *environment variable*, and the meaning of the name and value, are implementation defined. 1/2

**Implementation defined:** The definition and meaning of an environment variable. 1.a/2

### Static Semantics

{AI95-00370-01} The library package Environment\_Variables has the following declaration: 2/2

```

package Ada.Environment_Variables is 3/2
 pragma Preelaborate(Environment_Variables);
 function Value (Name : in String) return String; 4/2
 {AI05-0285-1} function Value (Name : in String; Default : in String) return 4.1/3
 String;
 function Exists (Name : in String) return Boolean; 5/2
 procedure Set (Name : in String; Value : in String); 6/2
 procedure Clear (Name : in String); 7/2
 procedure Clear;
 {AI05-0248-1} procedure Iterate 8/3
 (Process : not null access procedure (Name, Value : in String));
end Ada.Environment_Variables; 9/2

function Value (Name : in String) return String; 10/2

```

{AI95-00370-01} If the external execution environment supports environment variables, then Value returns the value of the environment variable with the given name. If no environment variable with the given name exists, then Constraint\_Error is propagated. If the execution environment does not support environment variables, then Program\_Error is propagated. 11/2

```

function Value (Name : in String; Default : in String) return String; 11.1/3

```

{AI05-0285-1} If the external execution environment supports environment variables and an environment variable with the given name currently exists, then Value returns its value; otherwise, it returns Default. 11.2/3

```

function Exists (Name : in String) return Boolean; 12/2

```

{AI95-00370-01} {AI05-0264-1} If the external execution environment supports environment variables and an environment variable with the given name currently exists, then Exists returns True; otherwise, it returns False. 13/3

```

procedure Set (Name : in String; Value : in String); 14/2

```

{AI95-00370-01} {AI05-0264-1} If the external execution environment supports environment variables, then Set first clears any existing environment variable with the given name, and then defines a single new environment variable with the given name and value. Otherwise, Program\_Error is propagated. 15/3

If implementation-defined circumstances prohibit the definition of an environment variable with the given name and value, then Constraint\_Error is propagated. 16/2

**Implementation defined:** The circumstances where an environment variable cannot be defined. 16.a/2

It is implementation defined whether there exist values for which the call Set(Name, Value) has the same effect as Clear (Name). 17/2

- 17.a/2        **Implementation defined:** Environment names for which Set has the effect of Clear.
- 18/2        **procedure** Clear (Name : in String);
- 19/3        {AI95-00370-01} {AI05-0264-1} {AI05-0269-1} If the external execution environment supports environment variables, then Clear deletes all existing environment variables with the given name. Otherwise, Program\_Error is propagated.
- 20/2        **procedure** Clear;
- 21/3        {AI95-00370-01} {AI05-0264-1} If the external execution environment supports environment variables, then Clear deletes all existing environment variables. Otherwise, Program\_Error is propagated.
- 22/3        {AI05-0248-1} **procedure** Iterate  
(Process : not null access procedure (Name, Value : in String));
- 23/3        {AI95-00370-01} {AI05-0264-1} If the external execution environment supports environment variables, then Iterate calls the subprogram designated by Process for each existing environment variable, passing the name and value of that environment variable. Otherwise, Program\_Error is propagated.
- 24/2        If several environment variables exist that have the same name, Process is called once for each such variable.

*Bounded (Run-Time) Errors*

- 25/2        {AI95-00370-01} It is a bounded error to call Value if more than one environment variable exists with the given name; the possible outcomes are that:
- 26/2        • one of the values is returned, and that same value is returned in subsequent calls in the absence of changes to the environment; or
- 27/2        • Program\_Error is propagated.

*Erroneous Execution*

- 28/2        {AI95-00370-01} Making calls to the procedures Set or Clear concurrently with calls to any subprogram of package Environment\_Variables, or to any instantiation of Iterate, results in erroneous execution.
- 29/2        Making calls to the procedures Set or Clear in the actual subprogram corresponding to the Process parameter of Iterate results in erroneous execution.

*Documentation Requirements*

- 30/2        {AI95-00370-01} An implementation shall document how the operations of this package behave if environment variables are changed by external mechanisms (for instance, calling operating system services).
- 30.a/2        **Documentation Requirement:** The behavior of package Environment\_Variables when environment variables are changed by external mechanisms.

*Implementation Permissions*

- 31/2        {AI95-00370-01} An implementation running on a system that does not support environment variables is permitted to define the operations of package Environment\_Variables with the semantics corresponding to the case where the external execution environment does support environment variables. In this case, it shall provide a mechanism to initialize a nonempty set of environment variables prior to the execution of a partition.

*Implementation Advice*

{AI95-00370-01} If the execution environment supports subprocesses, the currently defined environment variables should be used to initialize the environment variables of a subprocess. 32/2

**Implementation Advice:** If the execution environment supports subprocesses, the current environment variables should be used to initialize the environment variables of a subprocess. 32.a/2

Changes to the environment variables made outside the control of this package should be reflected immediately in the effect of the operations of this package. Changes to the environment variables made using this package should be reflected immediately in the external execution environment. This package should not perform any buffering of the environment variables. 33/2

**Implementation Advice:** Changes to the environment variables made outside the control of Environment\_Variables should be reflected immediately. 33.a/2

*Extensions to Ada 95*

{AI95-00370-01} Package Environment\_Variables is new. 33.b/2

*Incompatibilities With Ada 2005*

{AI05-0285-1} A new overloaded function Value is added to Environment\_Variables. If Environment\_Variables is referenced in a use\_clause, and an entity E with the name Value is defined in a package that is also referenced in a use\_clause, the entity E may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur. 33.c/3

**A.18 Containers**

{AI95-00302-03} This clause presents the specifications of the package Containers and several child packages, which provide facilities for storing collections of elements. 1/2

**Glossary entry:** A container is an object that contain other objects all of the same type, which could be class-wide. Several predefined container types are provided by the children of package Ada.Containers (see A.18.1). 1.a/1/3

{AI95-00302-03} A variety of sequence and associative containers are provided. Each container includes a cursor type. A cursor is a reference to an element within a container. Many operations on cursors are common to all of the containers. A cursor referencing an element in a container is considered to be overlapping with the container object itself. 2/2

**Reason:** The last sentence is intended to clarify that operations that just use a cursor are on the same footing as operations that use a container in terms of the reentrancy rules of Annex A. 2.a/2

{AI95-00302-03} Within this clause we provide Implementation Advice for the desired average or worst case time complexity of certain operations on a container. This advice is expressed using the Landau symbol  $O(X)$ . Presuming  $f$  is some function of a length parameter  $N$  and  $t(N)$  is the time the operation takes (on average or worst case, as specified) for the length  $N$ , a complexity of  $O(f(N))$  means that there exists a finite  $A$  such that for any  $N$ ,  $t(N)/f(N) < A$ . 3/2

**Discussion:** Of course, an implementation can do better than a specified  $O(f(N))$ : for example,  $O(1)$  meets the requirements for  $O(\log N)$ . 3.a/2

This concept seems to have as many names as there are authors. We used “Landau symbol” because that’s what our reference does. But we’d also seen this referred as big-O notation (sometimes written as *big-oh*), and as Bachmann notation. Whatever the name, it always has the above definition. 3.b/2

If the advice suggests that the complexity should be less than  $O(f(N))$ , then for any arbitrarily small positive real  $D$ , there should exist a positive integer  $M$  such that for all  $N > M$ ,  $t(N)/f(N) < D$ . 4/2

{AI05-0001-1} {AI05-0044-1} When a formal function is used to provide an ordering for a container, it is generally required to define a strict weak ordering. A function “ $<$ ” defines a *strict weak ordering* if it is irreflexive, asymmetric, transitive, and in addition, if  $x < y$  for any values  $x$  and  $y$ , then for all other values  $z$ ,  $(x < z)$  or  $(z < y)$ . 5/3

- 5.a/3 {AI95-00302-03} {AI05-0299-1} This subclause provides a number of useful containers for Ada. Only the most useful containers are provided. Ones that are relatively easy to code, redundant, or rarely used are omitted from this set, even if they are generally included in containers libraries.
- 5.b/2 The containers packages are modeled on the Standard Template Library (STL), an algorithms and data structure library popularized by Alexander Stepanov, and included in the C++ standard library. The structure and terminology differ from the STL where that better maps to common Ada usage. For instance, what the STL calls “iterators” are called “cursors” here.
- 5.c/2 The following major nonlimited containers are provided:
- 5.d/2 • (Expandable) Vectors of any nonlimited type;
  - 5.e/2 • Doubly-linked Lists of any nonlimited type;
  - 5.f/2 • Hashed Maps keyed by any nonlimited hashable type, and containing any nonlimited type;
  - 5.g/2 • Ordered Maps keyed by any nonlimited ordered type, and containing any nonlimited type;
  - 5.h/3 • {AI05-0136-1} Hashed Sets of any nonlimited hashable type;
  - 5.i/3 • {AI05-0136-1} Ordered Sets of any nonlimited ordered type;
  - 5.i.1/3 • {AI05-0136-1} Multiway Trees of any nonlimited type;
  - 5.i.2/3 • {AI05-0069-1} Holders of any (indefinite) nonlimited type;
  - 5.i.3/3 • {AI05-0159-1} Synchronized queues of any definite nonlimited type; and
  - 5.i.4/3 • {AI05-0159-1} Priority queues of any definite nonlimited type.
- 5.j/3 {AI05-0001-1} Separate versions for definite and indefinite element types are provided, as those for definite types can be implemented more efficiently. Similarly, a separate bounded version is provided in order to give more predictable memory usage.
- 5.k/2 Each container includes a cursor, which is a reference to an element within a container. Cursors generally remain valid as long as the container exists and the element referenced is not deleted. Many operations on cursors are common to all of the containers. This makes it possible to write generic algorithms that work on any kind of container.
- 5.l/2 The containers packages are structured so that additional packages can be added in the future. Indeed, we hope that these packages provide the basis for a more extensive secondary standard for containers.
- 5.m/2 If containers with similar functionality (but different performance characteristics) are provided (by the implementation or by a secondary standard), we suggest that a prefix be used to identify the class of the functionality: "Ada.Containers.Bounded\_Sets" (for a set with a maximum number of elements); "Ada.Containers.Protected\_Maps" (for a map which can be accessed by multiple tasks at one time); "Ada.Containers.Persistent\_Vectors" (for a persistent vector which continues to exist between executions of a program) and so on.
- 5.n/2 Note that the language already includes several requirements that are important to the use of containers. These include:
- 5.o/2 • Library packages must be reentrant – multiple tasks can use the packages as long as they operate on separate containers. Thus, it is only necessary for a user to protect a container if a single container needs to be used by multiple tasks.
  - 5.p/2 • Language-defined types must stream "properly". That means that the stream attributes can be used to implement persistence of containers when necessary, and containers can be passed between partitions of a program.
  - 5.q/2 • Equality of language-defined types must compose “properly”. This means that the version of "=" directly used by users is the same one that will be used in generics and in predefined equality operators of types with components of the containers and/or cursors. This prevents the abstraction from breaking unexpectedly.
  - 5.q.1/3 • {AI05-0048-1} Redispaching is not allowed (unless it is required). That means that overriding a container operation will not change the behavior of any other predefined container operation. This provides a stable base for extensions.
- 5.r/2 If a container's element type is controlled, the point at which the element is finalized will depend on the implementation of the container. We do not specify precisely where this will happen (it will happen no later than the finalization of the container, of course) in order to give implementation's flexibility to cache, block, or split the nodes of the container. In particular, Delete does not necessarily finalize the element; the implementation may (or may not) hold the space for reuse.
- 5.s/2 This is not likely to be a hardship, as the element type has to be nonlimited. Types used to manage scarce resources generally need to be limited. Otherwise, the amount of resources needed is hard to control, as the language allows a lot of variation in the number or order of adjusts/finalizations. For common uses of nonlimited controlled types such as managing storage, the types already have to manage arbitrary copies.

The use of controlled types also brings up the possibility of failure of finalization (and thus deallocation) of an element. This is a “serious bug”, as AI95-179 puts it, so we don't try to specify what happens in that case. The implementation should propagate the exception. 5.t/2

**Implementation Note:** It is expected that exceptions propagated from these operations do not damage containers. That is, if `Storage_Error` is propagated because of an allocation failure, or `Constraint_Error` is propagated by the assignment of elements, the container can continue to be used without further exceptions. The intent is that it should be possible to recover from errors without losing data. We don't try to state this formally in most cases, because it is hard to define precisely what is and is not allowed behavior. 5.u/2

**Implementation Note:** When this clause says that the behavior of something is unspecified, we really mean that any result of executing Ada code short of erroneous execution is allowed. We do not mean that memory not belonging to the parameters of the operation can be trashed. When we mean to allow erroneous behavior, we specifically say that execution is erroneous. All this means if the containers are written in Ada is that checks should not be suppressed or removed assuming some behavior of other code, and that the implementation should take care to avoid creating internal dangling accesses by assuming behavior from generic formal parameters that can't be guaranteed. We don't try to say this normatively because it would be fairly complex, and implementers are unlikely to increase their support costs by fielding implementations that are unstable if given buggy hash functions, et al. 5.v/2

*Extensions to Ada 95*

{AI95-00302-03} {AI05-0299-1} This subclause is new. It just provides an introduction to the following subclauses. 5.w/3

*Wording Changes from Ada 2005*

{AI05-0044-1} **Correction:** Added a definition of strict weak ordering. 5.x/3

## A.18.1 The Package Containers

{AI95-00302-03} The package Containers is the root of the containers subsystem. 1/2

*Static Semantics*

{AI95-00302-03} The library package Containers has the following declaration: 2/2

```
package Ada.Containers is
 pragma Pure(Containers);
 type Hash_Type is mod implementation-defined;
 type Count_Type is range 0 .. implementation-defined;
 {AI05-0001-1} Capacity_Error : exception;
end Ada.Containers;
3/2
4/2
5/2
5.1/3
6/2
```

{AI95-00302-03} `Hash_Type` represents the range of the result of a hash function. `Count_Type` represents the (potential or actual) number of elements of a container. 7/2

**Implementation defined:** The value of `Containers.Hash_Type'Modulus`. The value of `Containers.Count_Type'Last`. 7.a/2

{AI05-0262-1} `Capacity_Error` is raised when the capacity of a container is exceeded. 7.1/3

*Implementation Advice*

{AI95-00302-03} `Hash_Type'Modulus` should be at least  $2^{**32}$ . `Count_Type'Last` should be at least  $2^{**31}-1$ . 8/2

**Implementation Advice:** `Containers.Hash_Type'Modulus` should be at least  $2^{**32}$ . `Containers.Count_Type'Last` should be at least  $2^{**31}-1$ . 8.a/2

**Discussion:** This is not a requirement so that these types can be declared properly on machines with native sizes that are not 32 bits. For instance, a 24-bit target could use  $2^{**24}$  for `Hash_Type'Modulus`. 8.b/2

*Extensions to Ada 95*

{AI95-00302-03} The package Containers is new. 8.c/2

- 8.d/3 {AI05-0001-1} Exception `Capacity_Error` is added to `Containers`. If `Containers` is referenced in a `use_clause`, and an entity with the name `Capacity_Error` is defined in a package that is also referenced in a `use_clause`, the entity `Capacity_Error` may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur.

## A.18.2 The Generic Package `Containers.Vectors`

- 1/2 The language-defined generic package `Containers.Vectors` provides private types `Vector` and `Cursor`, and a set of operations for each type. A vector container allows insertion and deletion at any position, but it is specifically optimized for insertion and deletion at the high end (the end with the higher index) of the container. A vector container also provides random access to its elements.
- 2/2 A vector container behaves conceptually as an array that expands as necessary as items are inserted. The *length* of a vector is the number of elements that the vector contains. The *capacity* of a vector is the maximum number of elements that can be inserted into the vector prior to it being automatically expanded.
- 3/2 Elements in a vector container can be referred to by an index value of a generic formal type. The first element of a vector always has its index value equal to the lower bound of the formal type.
- 4/2 A vector container may contain *empty elements*. Empty elements do not have a specified value.
- 4.a/2 **Implementation Note:** Vectors are not intended to be sparse (that is, there are elements at all defined positions). Users are expected to use other containers (like a `Map`) when they need sparse structures (there is a Note to this effect at the end of this subclause).
- 4.b/2 The internal array is a conceptual model of a vector. There is no requirement for an implementation to be a single contiguous array.

### Static Semantics

- 5/2 {AI95-00302-03} The generic library package `Containers.Vectors` has the following declaration:
- ```
6/3 {AI05-0084-1} {AI05-0212-1} with Ada.Iterator_Interfaces;
generic
  type Index_Type is range <>;
  type Element_Type is private;
  with function "=" (Left, Right : Element_Type)
    return Boolean is <>;
package Ada.Containers.Vectors is
  pragma Preelaborate(Vectors);
  pragma Remote_Types(Vectors);

7/2  subtype Extended_Index is
      Index_Type'Base range
        Index_Type'First-1 ..
        Index_Type'Min (Index_Type'Base'Last - 1, Index_Type'Last) + 1;
      No_Index : constant Extended_Index := Extended_Index'First;

8/3 {AI05-0212-1}  type Vector is tagged private
      with Constant_Indexing => Constant_Reference,
            Variable_Indexing => Reference,
            Default_Iterator  => Iterate,
            Iterator_Element  => Element_Type;
      pragma Preelaborable_Initialization(Vector);

9/2  type Cursor is private;
      pragma Preelaborable_Initialization(Cursor);

10/2  Empty_Vector : constant Vector;

11/2  No_Element : constant Cursor;

11.1/3 {AI05-0212-1}  function Has_Element (Position : Cursor) return Boolean;

11.2/3 {AI05-0212-1}  package Vector_Iterator_Interfaces is new
      Ada.Iterator_Interfaces (Cursor, Has_Element);
```

```

function "=" (Left, Right : Vector) return Boolean;                                12/2
function To_Vector (Length : Count_Type) return Vector;                          13/2
function To_Vector
  (New_Item : Element_Type;
   Length   : Count_Type) return Vector;                                        14/2

<i>This paragraph was deleted.</i> {AI05-0212-1}	72/3

```

73/2     procedure Iterate
         (Container : in Vector;
          Process   : not null access procedure (Position : in Cursor));
74/2     procedure Reverse_Iterate
         (Container : in Vector;
          Process   : not null access procedure (Position : in Cursor));
74.1/3   {AI05-0212-1} function Iterate (Container : in Vector)
         return Vector_Iterator_Interfaces.Reversible_Iterator'Class;
74.2/3   {AI05-0212-1} function Iterate (Container : in Vector; Start : in Cursor)
         return Vector_Iterator_Interfaces.Reversible_Iterator'Class;
75/2     generic
         with function "<" (Left, Right : Element_Type)
           return Boolean is <>;
         package Generic_Sorting is
76/2         function Is_Sorted (Container : Vector) return Boolean;
77/2         procedure Sort (Container : in out Vector);
78/2         procedure Merge (Target  : in out Vector;
                          Source   : in out Vector);
79/2     end Generic_Sorting;
80/2     private
81/2         ... -- not specified by the language
82/2     end Ada.Containers.Vectors;
83/2     {AI95-00302-03} The actual function for the generic formal function "=" on Element_Type values is
expected to define a reflexive and symmetric relationship and return the same result value each time it is
called with a particular pair of values. If it behaves in some other manner, the functions defined to use it
return an unspecified value. The exact arguments and number of calls of this generic formal function by
the functions defined to use it are unspecified.
83.a/2     Ramification: The “functions defined to use it” are Find, Find_Index, Reverse_Find, Reverse_Find_Index, and "=" for
Vectors. This list is a bit too long to give explicitly.
83.b/2     If the actual function for "=" is not symmetric and consistent, the result returned by any of the functions defined to use
"=" cannot be predicted. The implementation is not required to protect against "=" raising an exception, or returning
random results, or any other “bad” behavior. And it can call "=" in whatever manner makes sense. But note that only
the results of the functions defined to use "=" are unspecified; other subprograms are not allowed to break if "=" is bad.
84/2     {AI95-00302-03} The type Vector is used to represent vectors. The type Vector needs finalization (see
7.6).
85/2     {AI95-00302-03} Empty_Vector represents the empty vector object. It has a length of 0. If an object of
type Vector is not otherwise initialized, it is initialized to the same value as Empty_Vector.
86/2     {AI95-00302-03} No_Element represents a cursor that designates no element. If an object of type Cursor
is not otherwise initialized, it is initialized to the same value as No_Element.
87/2     {AI95-00302-03} The predefined "=" operator for type Cursor returns True if both cursors are
No_Element, or designate the same element in the same container.
88/2     {AI95-00302-03} Execution of the default implementation of the Input, Output, Read, or Write attribute
of type Cursor raises Program_Error.
88.a/2     Reason: A cursor will probably be implemented in terms of one or more access values, and the effects of streaming
access values is unspecified. Rather than letting the user stream junk by accident, we mandate that streaming of cursors
raise Program_Error by default. The attributes can always be specified if there is a need to support streaming.
88.1/3   {AI05-0001-1} {AI05-0262-1} Vector'Write for a Vector object V writes Length(V) elements of the
vector to the stream. It also may write additional information about the vector.

```

- {AI05-0001-1} {AI05-0262-1} Vector'Read reads the representation of a vector from the stream, and assigns to *Item* a vector with the same length and elements as was written by Vector'Write. 88.2/3
- Implementation Note:** The Standard requires streaming of all language-defined nonlimited types (including containers) to "work" (see 13.13.2). In addition, we do not want all of the elements that make up the capacity of the vector streamed, as those beyond the length of the container have undefined contents (and might cause bad things when read back in). This will require a custom stream attribute implementation; the language-defined default implementation will not work (even for a bounded form, as that would most likely stream the entire capacity of the vector). There is a separate requirement that the unbounded and Bounded form use the same streaming representation for the same element type, see A.18.19. 88.b/3
- {AI95-00302-03} No_Index represents a position that does not correspond to any element. The subtype Extended_Index includes the indices covered by Index_Type plus the value No_Index and, if it exists, the successor to the Index_Type'Last. 89/2
- Discussion:** We require the existence of Index_Type'First – 1, so that No_Index and Last_Index of an empty vector is well-defined. We don't require the existence of Index_Type'Last + 1, as it is only used as the position of insertions (and needs to be allowed only when inserting an empty vector). 89.a/2
- {AI05-0001-1} If an operation attempts to modify the vector such that the position of the last element would be greater than Index_Type'Last, then the operation propagates Constraint_Error. 89.1/3
- Reason:** We don't want to require an implementation to go to heroic efforts to handle index values larger than the base type of the index subtype. 89.b/3
- {AI95-00302-03} [Some operations of this generic package have access-to-subprogram parameters. To ensure such operations are well-defined, they guard against certain actions by the designated subprogram. In particular, some operations check for "tampering with cursors" of a container because they depend on the set of elements of the container remaining constant, and others check for "tampering with elements" of a container because they depend on elements of the container not being replaced.] 90/2
- {AI95-00302-03} A subprogram is said to *tamper with cursors* of a vector object *V* if: 91/2
- it inserts or deletes elements of *V*, that is, it calls the Insert, Insert_Space, Clear, Delete, or Set_Length procedures with *V* as a parameter; or 92/2

To be honest: Operations which are defined to be equivalent to a call on one of these operations also are included. Similarly, operations which call one of these as part of their definition are included. 92.a/2
 - it finalizes *V*; or 93/2
 - {AI05-0001-1} it calls the Assign procedure with *V* as the Target parameter; or 93.1/3

Ramification: We don't need to explicitly mention assignment_statement, because that finalizes the target object as part of the operation, and finalization of an object is already defined as tampering with cursors. 93.a.1/3
 - it calls the Move procedure with *V* as a parameter. 94/2

Discussion: Swap, Sort, and Merge copy elements rather than reordering them, so they don't tamper with cursors. 94.a/2
- {AI95-00302-03} A subprogram is said to *tamper with elements* of a vector object *V* if: 95/2
- it tampers with cursors of *V*; or 96/2
 - it replaces one or more elements of *V*, that is, it calls the Replace_Element, Reverse_Elements, or Swap procedures or the Sort or Merge procedures of an instance of Generic_Sorting with *V* as a parameter. 97/2

Reason: Complete replacement of an element can cause its memory to be deallocated while another operation is holding onto a reference to it. That can't be allowed. However, a simple modification of (part of) an element is not a problem, so Update_Element does not cause a problem. 97.a/2
- {AI05-0265-1} When tampering with cursors is *prohibited* for a particular vector object *V*, Program_Error is propagated by a call of any language-defined subprogram that is defined to tamper with the cursors of *V*, leaving *V* unmodified. Similarly, when tampering with elements is *prohibited* for a 97.1/3

particular vector object V , `Program_Error` is propagated by a call of any language-defined subprogram that is defined to tamper with the elements of V [(or tamper with the cursors of V)], leaving V unmodified.

- 97.b/3 **Proof:** Tampering with elements includes tampering with cursors, so we mention it only from completeness in the second sentence.
- 97.2/3 **function** `Has_Element` (`Position` : `Cursor`) **return** `Boolean`;
- 97.3/3 {AI05-0212-1} Returns True if `Position` designates an element, and returns False otherwise.
- 97.c/3 **To be honest:** {AI05-0005-1} {AI05-0212-1} This function might not detect cursors that designate deleted elements; such cursors are invalid (see below) and the result of calling `Has_Element` with an invalid cursor is unspecified (but not erroneous).
- 98/2 **function** `"="` (`Left`, `Right` : `Vector`) **return** `Boolean`;
- 99/3 {AI95-00302-03} {AI05-0264-1} If `Left` and `Right` denote the same vector object, then the function returns True. If `Left` and `Right` have different lengths, then the function returns False. Otherwise, it compares each element in `Left` to the corresponding element in `Right` using the generic formal equality operator. If any such comparison returns False, the function returns False; otherwise, it returns True. Any exception raised during evaluation of element equality is propagated.
- 99.a/2 **Implementation Note:** This wording describes the canonical semantics. However, the order and number of calls on the formal equality function is unspecified for all of the operations that use it in this package, so an implementation can call it as many or as few times as it needs to get the correct answer. Specifically, there is no requirement to call the formal equality additional times once the answer has been determined.
- 100/2 **function** `To_Vector` (`Length` : `Count_Type`) **return** `Vector`;
- 101/2 {AI95-00302-03} Returns a vector with a length of `Length`, filled with empty elements.
- 102/2 **function** `To_Vector`
 (`New_Item` : `Element_Type`;
 `Length` : `Count_Type`) **return** `Vector`;
- 103/2 {AI95-00302-03} Returns a vector with a length of `Length`, filled with elements initialized to the value `New_Item`.
- 104/2 **function** `"&"` (`Left`, `Right` : `Vector`) **return** `Vector`;
- 105/2 {AI95-00302-03} Returns a vector comprising the elements of `Left` followed by the elements of `Right`.
- 106/2 **function** `"&"` (`Left` : `Vector`;
 `Right` : `Element_Type`) **return** `Vector`;
- 107/2 {AI95-00302-03} Returns a vector comprising the elements of `Left` followed by the element `Right`.
- 108/2 **function** `"&"` (`Left` : `Element_Type`;
 `Right` : `Vector`) **return** `Vector`;
- 109/2 {AI95-00302-03} Returns a vector comprising the element `Left` followed by the elements of `Right`.
- 110/2 **function** `"&"` (`Left`, `Right` : `Element_Type`) **return** `Vector`;
- 111/2 {AI95-00302-03} Returns a vector comprising the element `Left` followed by the element `Right`.
- 112/2 **function** `Capacity` (`Container` : `Vector`) **return** `Count_Type`;
- 113/2 {AI95-00302-03} Returns the capacity of `Container`.

procedure Reserve_Capacity (Container : in out Vector; Capacity : in Count_Type);	114/2
<i>{AI95-00302-03}</i> <i>{AI05-0001-1}</i> <i>{AI05-0264-1}</i> If the capacity of Container is already greater than or equal to Capacity, then Reserve_Capacity has no effect. Otherwise, Reserve_Capacity allocates additional storage as necessary to ensure that the length of the resulting vector can become at least the value Capacity without requiring an additional call to Reserve_Capacity, and is large enough to hold the current length of Container. Reserve_Capacity then, as necessary, moves elements into the new storage and deallocates any storage no longer needed. Any exception raised during allocation is propagated and Container is not modified.	115/3
Discussion: Expanding the internal array can be done by allocating a new, longer array, copying the elements, and deallocating the original array. This may raise Storage_Error, or cause an exception from a controlled subprogram. We require that a failed Reserve_Capacity does not lose any elements if an exception occurs, but we do not require a specific order of evaluations or copying.	115.a/2
This routine is used to preallocate the internal array to the specified capacity such that future Inserts do not require memory allocation overhead. Therefore, the implementation should allocate the needed memory to make that true at this point, even though the visible semantics could be preserved by waiting until the memory is needed. This doesn't apply to the indefinite element container, because elements will have to be allocated individually.	115.b/2
The implementation does not have to contract the internal array if the capacity is reduced, as any capacity greater than or equal to the specified capacity is allowed.	115.c/2
function Length (Container : Vector) return Count_Type;	116/2
<i>{AI95-00302-03}</i> Returns the number of elements in Container.	117/2
procedure Set_Length (Container : in out Vector; Length : in Count_Type);	118/2
<i>{AI95-00302-03}</i> <i>{AI05-0264-1}</i> If Length is larger than the capacity of Container, Set_Length calls Reserve_Capacity (Container, Length), then sets the length of the Container to Length. If Length is greater than the original length of Container, empty elements are added to Container; otherwise, elements are removed from Container.	119/3
Ramification: No elements are moved by this operation; any new empty elements are added at the end. This follows from the rules that a cursor continues to designate the same element unless the routine is defined to make the cursor ambiguous or invalid; this operation does not do that.	119.a/2
function Is_Empty (Container : Vector) return Boolean;	120/2
<i>{AI95-00302-03}</i> Equivalent to Length (Container) = 0.	121/2
procedure Clear (Container : in out Vector);	122/2
<i>{AI95-00302-03}</i> Removes all the elements from Container. The capacity of Container does not change.	123/2
function To_Cursor (Container : Vector; Index : Extended_Index) return Cursor;	124/2
<i>{AI95-00302-03}</i> If Index is not in the range First_Index (Container) .. Last_Index (Container), then No_Element is returned. Otherwise, a cursor designating the element at position Index in Container is returned.	125/2
function To_Index (Position : Cursor) return Extended_Index;	126/2
<i>{AI95-00302-03}</i> If Position is No_Element, No_Index is returned. Otherwise, the index (within its containing vector) of the element designated by Position is returned.	127/2
Ramification: This implies that the index is determinable from a bare cursor alone. The basic model is that a vector cursor is implemented as a record containing an access to the vector container and an index value. This does constrain implementations, but it also allows all of the cursor operations to be defined in terms of the corresponding index operation (which should be primary for a vector).	127.a/2

- 128/2 **function** Element (Container : Vector;
 Index : Index_Type)
 return Element_Type;
- 129/2 {AI95-00302-03} If Index is not in the range First_Index (Container) .. Last_Index (Container), then Constraint_Error is propagated. Otherwise, Element returns the element at position Index.
- 130/2 **function** Element (Position : Cursor) **return** Element_Type;
- 131/2 {AI95-00302-03} If Position equals No_Element, then Constraint_Error is propagated. Otherwise, Element returns the element designated by Position.
- 132/2 **procedure** Replace_Element (Container : **in out** Vector;
 Index : **in** Index_Type;
 New_Item : **in** Element_Type);
- 133/3 {AI95-00302-03} {AI05-0264-1} If Index is not in the range First_Index (Container) .. Last_Index (Container), then Constraint_Error is propagated. Otherwise, Replace_Element assigns the value New_Item to the element at position Index. Any exception raised during the assignment is propagated. The element at position Index is not an empty element after successful call to Replace_Element.
- 134/2 **procedure** Replace_Element (Container : **in out** Vector;
 Position : **in** Cursor;
 New_Item : **in** Element_Type);
- 135/3 {AI95-00302-03} {AI05-0264-1} If Position equals No_Element, then Constraint_Error is propagated; if Position does not designate an element in Container, then Program_Error is propagated. Otherwise, Replace_Element assigns New_Item to the element designated by Position. Any exception raised during the assignment is propagated. The element at Position is not an empty element after successful call to Replace_Element.
- 135.a/3 **Ramification:** {AI05-0212-1} Replace_Element, Update_Element, and Reference are the only ways that an element can change from empty to nonempty. Also see the note following Update_Element.
- 136/2 **procedure** Query_Element
 (Container : **in** Vector;
 Index : **in** Index_Type;
 Process : **not null access procedure** (Element : **in** Element_Type));
- 137/3 {AI95-00302-03} {AI05-0265-1} If Index is not in the range First_Index (Container) .. Last_Index (Container), then Constraint_Error is propagated. Otherwise, Query_Element calls Process.all with the element at position Index as the argument. Tampering with the elements of Container is prohibited during the execution of the call on Process.all. Any exception raised by Process.all is propagated.
- 137.a/2 **Reason:** {AI05-0005-1} The “tamper with the elements” check is intended to prevent the Element parameter of Process from being replaced or deleted outside of Process. The check prevents data loss (if Element_Type is passed by copy) or erroneous execution (if Element_Type is an unconstrained type in an indefinite container).
- 138/2 **procedure** Query_Element
 (Position : **in** Cursor;
 Process : **not null access procedure** (Element : **in** Element_Type));
- 139/3 {AI95-00302-03} {AI05-0021-1} {AI05-0265-1} If Position equals No_Element, then Constraint_Error is propagated. Otherwise, Query_Element calls Process.all with the element designated by Position as the argument. Tampering with the elements of the vector that contains the element designated by Position is prohibited during the execution of the call on Process.all. Any exception raised by Process.all is propagated.

procedure Update_Element (Container : in out Vector; Index : in Index_Type; Process : not null access procedure (Element : in out Element_Type));	140/2
{AI95-00302-03} {AI05-0265-1} If Index is not in the range First_Index (Container) .. Last_Index (Container), then Constraint_Error is propagated. Otherwise, Update_Element calls Process.all with the element at position Index as the argument. Tampering with the elements of Container is prohibited during the execution of the call on Process.all. Any exception raised by Process.all is propagated.	141/3
If Element_Type is unconstrained and definite, then the actual Element parameter of Process.all shall be unconstrained.	142/2
Ramification: This means that the elements cannot be directly allocated from the heap; it must be possible to change the discriminants of the element in place.	142.a/2
The element at position Index is not an empty element after successful completion of this operation.	143/2
Ramification: Since reading an empty element is a bounded error, attempting to use this procedure to replace empty elements may fail. Use Replace_Element to do that reliably.	143.a/2
procedure Update_Element (Container : in out Vector; Position : in Cursor; Process : not null access procedure (Element : in out Element_Type));	144/2
{AI95-00302-03} {AI05-0264-1} {AI05-0265-1} If Position equals No_Element, then Constraint_Error is propagated; if Position does not designate an element in Container, then Program_Error is propagated. Otherwise, Update_Element calls Process.all with the element designated by Position as the argument. Tampering with the elements of Container is prohibited during the execution of the call on Process.all. Any exception raised by Process.all is propagated.	145/3
If Element_Type is unconstrained and definite, then the actual Element parameter of Process.all shall be unconstrained.	146/2
The element designated by Position is not an empty element after successful completion of this operation.	147/2
type Constant_Reference_Type (Element : not null access constant Element_Type) is private with Implicit_Dereference => Element;	147.1/3
type Reference_Type (Element : not null access Element_Type) is private with Implicit_Dereference => Element;	147.2/3
{AI05-0212-1} The types Constant_Reference_Type and Reference_Type need finalization.	147.3/3
The default initialization of an object of type Constant_Reference_Type or Reference_Type propagates Program_Error.	147.4/3
Reason: It is expected that Reference_Type (and Constant_Reference_Type) will be a controlled type, for which finalization will have some action to terminate the tampering check for the associated container. If the object is created by default, however, there is no associated container. Since this is useless, and supporting this case would take extra work, we define it to raise an exception.	147.a/3
function Constant_Reference (Container : aliased in Vector; Index : in Index_Type) return Constant_Reference_Type;	147.5/3
{AI05-0212-1} {AI05-0269-1} This function (combined with the Constant_Indexing and Implicit_Dereference aspects) provides a convenient way to gain read access to an individual element of a vector given an index value.	147.6/3

- 147.7/3 *{AI05-0212-1}* *{AI05-0265-1}* If `Index` is not in the range `First_Index (Container) .. Last_Index (Container)`, then `Constraint_Error` is propagated. Otherwise, `Constant_Reference` returns an object whose discriminant is an access value that designates the element at position `Index`. Tampering with the elements of `Container` is prohibited while the object returned by `Constant_Reference` exists and has not been finalized.
- 147.8/3 **function** `Reference` (`Container` : **aliased in out** `Vector`;
 `Index` : **in** `Index_Type`)
return `Reference_Type`;
- 147.9/3 *{AI05-0212-1}* *{AI05-0269-1}* This function (combined with the `Variable_Indexing` and `Implicit_Dereference` aspects) provides a convenient way to gain read and write access to an individual element of a vector given an index value.
- 147.10/3 *{AI05-0212-1}* *{AI05-0265-1}* If `Index` is not in the range `First_Index (Container) .. Last_Index (Container)`, then `Constraint_Error` is propagated. Otherwise, `Reference` returns an object whose discriminant is an access value that designates the element at position `Index`. Tampering with the elements of `Container` is prohibited while the object returned by `Reference` exists and has not been finalized.
- 147.11/3 The element at position `Index` is not an empty element after successful completion of this operation.
- 147.12/3 **function** `Constant_Reference` (`Container` : **aliased in** `Vector`;
 `Position` : **in** `Cursor`)
return `Constant_Reference_Type`;
- 147.13/3 *{AI05-0212-1}* *{AI05-0269-1}* This function (combined with the `Constant_Indexing` and `Implicit_Dereference` aspects) provides a convenient way to gain read access to an individual element of a vector given a cursor.
- 147.14/3 *{AI05-0212-1}* *{AI05-0265-1}* If `Position` equals `No_Element`, then `Constraint_Error` is propagated; if `Position` does not designate an element in `Container`, then `Program_Error` is propagated. Otherwise, `Constant_Reference` returns an object whose discriminant is an access value that designates the element designated by `Position`. Tampering with the elements of `Container` is prohibited while the object returned by `Constant_Reference` exists and has not been finalized.
- 147.15/3 **function** `Reference` (`Container` : **aliased in out** `Vector`;
 `Position` : **in** `Cursor`)
return `Reference_Type`;
- 147.16/3 *{AI05-0212-1}* *{AI05-0269-1}* This function (combined with the `Variable_Indexing` and `Implicit_Dereference` aspects) provides a convenient way to gain read and write access to an individual element of a vector given a cursor.
- 147.17/3 *{AI05-0212-1}* *{AI05-0265-1}* If `Position` equals `No_Element`, then `Constraint_Error` is propagated; if `Position` does not designate an element in `Container`, then `Program_Error` is propagated. Otherwise, `Reference` returns an object whose discriminant is an access value that designates the element designated by `Position`. Tampering with the elements of `Container` is prohibited while the object returned by `Reference` exists and has not been finalized.
- 147.18/3 The element designated by `Position` is not an empty element after successful completion of this operation.
- 147.19/3 **procedure** `Assign` (`Target` : **in out** `Vector`; `Source` : **in** `Vector`);
- 147.20/3 *{AI05-0001-1}* *{AI05-0248-1}* *{AI05-0262-1}* If `Target` denotes the same object as `Source`, the operation has no effect. If the length of `Source` is greater than the capacity of `Target`,

Reserve_Capacity (Target, Length (Source)) is called. The elements of Source are then copied to Target as for an assignment_statement assigning Source to Target (this includes setting the length of Target to be that of Source).

Discussion: {AI05-0005-1} This routine exists for compatibility with the bounded vector container. For an unbounded vector, Assign (A, B) and A := B behave identically. For a bounded vector, := will raise an exception if the container capacities are different, while Assign will not raise an exception if there is enough room in the target. 147.b/3

```
function Copy (Source : Vector; Capacity : Count_Type := 0)
return Vector; 147.21/3
```

{AI05-0001-1} Returns a vector whose elements are initialized from the corresponding elements of Source. If Capacity is 0, then the vector capacity is the length of Source; if Capacity is equal to or greater than the length of Source, the vector capacity is at least the specified value. Otherwise, the operation propagates Capacity_Error. 147.22/3

```
procedure Move (Target : in out Vector;
                Source : in out Vector); 148/2
```

{AI95-00302-03} {AI05-0001-1} {AI05-0248-1} If Target denotes the same object as Source, then the operation has no effect. Otherwise, Move first calls Reserve_Capacity (Target, Length (Source)) and then Clear (Target); then, each element from Source is removed from Source and inserted into Target in the original order. The length of Source is 0 after a successful call to Move. 149/3

Discussion: The idea is that the internal array is removed from Source and moved to Target. (See the Implementation Advice for Move). If Capacity (Target) /= 0, the previous internal array may need to be deallocated. We don't mention this explicitly, because it is covered by the "no memory loss" Implementation Requirement. 149.a/2

```
procedure Insert (Container : in out Vector;
                 Before     : in     Extended_Index;
                 New_Item   : in     Vector); 150/2
```

{AI95-00302-03} {AI05-0264-1} If Before is not in the range First_Index (Container) .. Last_Index (Container) + 1, then Constraint_Error is propagated. If Length(New_Item) is 0, then Insert does nothing. Otherwise, it computes the new length *NL* as the sum of the current length and Length (New_Item); if the value of Last appropriate for length *NL* would be greater than Index_Type'Last, then Constraint_Error is propagated. 151/3

If the current vector capacity is less than *NL*, Reserve_Capacity (Container, *NL*) is called to increase the vector capacity. Then Insert slides the elements in the range Before .. Last_Index (Container) up by Length(New_Item) positions, and then copies the elements of New_Item to the positions starting at Before. Any exception raised during the copying is propagated. 152/2

Ramification: Moving the elements does not necessarily involve copying. Similarly, since Reserve_Capacity does not require the copying of elements, it does not need to be explicitly called (the implementation can combine the operations if it wishes to). 152.a/2

```
procedure Insert (Container : in out Vector;
                 Before     : in     Cursor;
                 New_Item   : in     Vector); 153/2
```

{AI95-00302-03} {AI05-0264-1} If Before is not No_Element, and does not designate an element in Container, then Program_Error is propagated. Otherwise, if Length(New_Item) is 0, then Insert does nothing. If Before is No_Element, then the call is equivalent to Insert (Container, Last_Index (Container) + 1, New_Item); otherwise, the call is equivalent to Insert (Container, To_Index (Before), New_Item); 154/3

Ramification: The check on Before checks that the cursor does not belong to some other Container. This check implies that a reference to the container is included in the cursor value. This wording is not meant to require detection of dangling cursors; such cursors are defined to be invalid, which means that execution is erroneous, and any result is allowed (including not raising an exception). 154.a/2

- 155/2 **procedure** Insert (Container : **in out** Vector;
 Before : **in** Cursor;
 New_Item : **in** Vector;
 Position : **out** Cursor);
- 156/2 {AI95-00302-03} If Before is not No_Element, and does not designate an element in Container, then Program_Error is propagated. If Before equals No_Element, then let *T* be Last_Index (Container) + 1; otherwise, let *T* be To_Index (Before). Insert (Container, *T*, New_Item) is called, and then Position is set to To_Cursor (Container, *T*).
- 156.a/2 **Discussion:** The messy wording is needed because Before is invalidated by Insert, and we don't want Position to be invalid after this call. An implementation probably only needs to copy Before to Position.
- 157/2 **procedure** Insert (Container : **in out** Vector;
 Before : **in** Extended_Index;
 New_Item : **in** Element_Type;
 Count : **in** Count_Type := 1);
- 158/2 {AI95-00302-03} Equivalent to Insert (Container, Before, To_Vector (New_Item, Count));
- 159/2 **procedure** Insert (Container : **in out** Vector;
 Before : **in** Cursor;
 New_Item : **in** Element_Type;
 Count : **in** Count_Type := 1);
- 160/2 {AI95-00302-03} Equivalent to Insert (Container, Before, To_Vector (New_Item, Count));
- 161/2 **procedure** Insert (Container : **in out** Vector;
 Before : **in** Cursor;
 New_Item : **in** Element_Type;
 Position : **out** Cursor;
 Count : **in** Count_Type := 1);
- 162/2 {AI95-00302-03} Equivalent to Insert (Container, Before, To_Vector (New_Item, Count), Position);
- 162.a/3 **Ramification:** {AI05-0257-1} If Count equals 0, Position will designate the element designated by Before, rather than a newly inserted element. Otherwise, Position will designate the first newly inserted element.
- 163/2 **procedure** Insert (Container : **in out** Vector;
 Before : **in** Extended_Index;
 Count : **in** Count_Type := 1);
- 164/3 {AI95-00302-03} {AI05-0264-1} If Before is not in the range First_Index (Container) .. Last_Index (Container) + 1, then Constraint_Error is propagated. If Count is 0, then Insert does nothing. Otherwise, it computes the new length *NL* as the sum of the current length and Count; if the value of Last appropriate for length *NL* would be greater than Index_Type'Last, then Constraint_Error is propagated.
- 165/2 If the current vector capacity is less than *NL*, Reserve_Capacity (Container, *NL*) is called to increase the vector capacity. Then Insert slides the elements in the range Before .. Last_Index (Container) up by Count positions, and then inserts elements that are initialized by default (see 3.3.1) in the positions starting at Before.
- 166/2 **procedure** Insert (Container : **in out** Vector;
 Before : **in** Cursor;
 Position : **out** Cursor;
 Count : **in** Count_Type := 1);
- 167/2 {AI95-00302-03} If Before is not No_Element, and does not designate an element in Container, then Program_Error is propagated. If Before equals No_Element, then let *T* be Last_Index (Container) + 1; otherwise, let *T* be To_Index (Before). Insert (Container, *T*, Count) is called, and then Position is set to To_Cursor (Container, *T*).

- Reason:** This routine exists mainly to ease conversion between Vector and List containers. Unlike `Insert_Space`, this routine default initializes the elements it inserts, which can be more expensive for some element types. 167.a/2
- ```

procedure Prepend (Container : in out Vector;
 New_Item : in Vector;
 Count : in Count_Type := 1);

```
- {AI95-00302-03} Equivalent to `Insert (Container, First_Index (Container), New_Item)`. 168/2
- ```

procedure Prepend (Container : in out Vector;
                    New_Item  : in      Element_Type;
                    Count     : in      Count_Type := 1);
  
```
- {AI95-00302-03} Equivalent to `Insert (Container, First_Index (Container), New_Item, Count)`. 170/2
- ```

procedure Append (Container : in out Vector;
 New_Item : in Vector);

```
- {AI95-00302-03} Equivalent to `Insert (Container, Last_Index (Container) + 1, New_Item)`. 171/2
- ```

procedure Append (Container : in out Vector;
                  New_Item  : in      Element_Type;
                  Count     : in      Count_Type := 1);
  
```
- {AI95-00302-03} Equivalent to `Insert (Container, Last_Index (Container) + 1, New_Item, Count)`. 172/2
- ```

procedure Insert_Space (Container : in out Vector;
 Before : in Extended_Index;
 Count : in Count_Type := 1);

```
- {AI95-00302-03} {AI05-0264-1} If `Before` is not in the range `First_Index (Container) .. Last_Index (Container) + 1`, then `Constraint_Error` is propagated. If `Count` is 0, then `Insert_Space` does nothing. Otherwise, it computes the new length  $NL$  as the sum of the current length and `Count`; if the value of `Last` appropriate for length  $NL$  would be greater than `Index_Type'Last`, then `Constraint_Error` is propagated. 173/2
- If the current vector capacity is less than  $NL$ , `Reserve_Capacity (Container, NL)` is called to increase the vector capacity. Then `Insert_Space` slides the elements in the range `Before .. Last_Index (Container)` up by `Count` positions, and then inserts empty elements in the positions starting at `Before`. 174/2
- ```

procedure Insert_Space (Container : in out Vector;
                        Before     : in      Cursor;
                        Position   : out     Cursor;
                        Count      : in      Count_Type := 1);
  
```
- {AI95-00302-03} If `Before` is not `No_Element`, and does not designate an element in `Container`, then `Program_Error` is propagated. If `Before` equals `No_Element`, then let T be `Last_Index (Container) + 1`; otherwise, let T be `To_Index (Before)`. `Insert_Space (Container, T, Count)` is called, and then `Position` is set to `To_Cursor (Container, T)`. 175/2
- ```

procedure Delete (Container : in out Vector;
 Index : in Extended_Index;
 Count : in Count_Type := 1);

```
- {AI95-00302-03} {AI05-0264-1} If `Index` is not in the range `First_Index (Container) .. Last_Index (Container) + 1`, then `Constraint_Error` is propagated. If `Count` is 0, `Delete` has no effect. Otherwise, `Delete` slides the elements (if any) starting at position `Index + Count` down to `Index`. Any exception raised during element assignment is propagated. 176/2
- Ramification:** If `Index + Count >= Last_Index (Container)`, this effectively truncates the vector (setting `Last_Index` to `Index - 1` and consequently sets `Length` to `Index - Index_Type'First`). 177/3
- 178/2
- 179/2
- 180/2
- 181/2
- 182/3
- 182.a/2

- 183/2     **procedure** Delete (Container : **in out** Vector;  
                           Position  : **in out** Cursor;  
                           Count     : **in**     Count\_Type := 1);
- 184/2     {AI95-00302-03} If Position equals No\_Element, then Constraint\_Error is propagated. If Position does not designate an element in Container, then Program\_Error is propagated. Otherwise, Delete (Container, To\_Index (Position), Count) is called, and then Position is set to No\_Element.
- 185/2     **procedure** Delete\_First (Container : **in out** Vector;  
                                   Count     : **in**     Count\_Type := 1);
- 186/2     {AI95-00302-03} Equivalent to Delete (Container, First\_Index (Container), Count).
- 187/2     **procedure** Delete\_Last (Container : **in out** Vector;  
                                   Count     : **in**     Count\_Type := 1);
- 188/3     {AI95-00302-03} {AI05-0264-1} If Length (Container) <= Count, then Delete\_Last is equivalent to Clear (Container). Otherwise, it is equivalent to Delete (Container, Index\_Type'Val(Index\_Type'Pos(Last\_Index (Container)) – Count + 1), Count).
- 189/2     {AI05-0092-1} **procedure** Reverse\_Elements (Container : **in out** Vector);
- 190/2     {AI95-00302-03} Reorders the elements of Container in reverse order.
- 190.a/2     **Discussion:** This can copy the elements of the vector — all cursors referencing the vector are ambiguous afterwards and may designate different elements afterwards.
- 191/2     **procedure** Swap (Container : **in out** Vector;  
                           I, J       : **in**     Index\_Type);
- 192/2     {AI95-00302-03} If either I or J is not in the range First\_Index (Container) .. Last\_Index (Container), then Constraint\_Error is propagated. Otherwise, Swap exchanges the values of the elements at positions I and J.
- 192.a/2     **To be honest:** The implementation is not required to actually copy the elements if it can do the swap some other way. But it is allowed to copy the elements if needed.
- 193/2     **procedure** Swap (Container : **in out** Vector;  
                           I, J       : **in**     Cursor);
- 194/2     {AI95-00302-03} If either I or J is No\_Element, then Constraint\_Error is propagated. If either I or J do not designate an element in Container, then Program\_Error is propagated. Otherwise, Swap exchanges the values of the elements designated by I and J.
- 194.a/2     **Ramification:** After a call to Swap, I designates the element value previously designated by J, and J designates the element value previously designated by I. The cursors do not become ambiguous from this operation.
- 194.b/2     **To be honest:** The implementation is not required to actually copy the elements if it can do the swap some other way. But it is allowed to copy the elements if needed.
- 195/2     **function** First\_Index (Container : Vector) **return** Index\_Type;
- 196/2     {AI95-00302-03} Returns the value Index\_Type'First.
- 196.a/2     **Discussion:** We'd rather call this “First”, but then calling most routines in here with First (Some\_Vect) would be ambiguous.
- 197/2     **function** First (Container : Vector) **return** Cursor;
- 198/2     {AI95-00302-03} If Container is empty, First returns No\_Element. Otherwise, it returns a cursor that designates the first element in Container.
- 199/2     **function** First\_Element (Container : Vector) **return** Element\_Type;
- 200/2     {AI95-00302-03} Equivalent to Element (Container, First\_Index (Container)).

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |       |

| {AI95-00302-03} {AI05-0264-1} If Position is not No_Element, and does not designate an element in Container, then Program_Error is propagated. Otherwise, Find searches the elements of Container for an element equal to Item (using the generic formal equality operator). The search starts at the first element if Position equals No_Element, and at the element designated by Position otherwise. It proceeds towards the last element of Container. If no equal element is found, then Find returns No_Element. Otherwise, it returns a cursor designating the first equal element encountered. | 218/3 |

- 219/2     **function** Reverse\_Find\_Index (Container : Vector;  
                                   Item        : Element\_Type;  
                                   Index       : Index\_Type := Index\_Type'Last)  
       **return** Extended\_Index;
- 220/2     {AI95-00302-03} Searches the elements of Container for an element equal to Item (using the generic formal equality operator). The search starts at position Index or, if Index is greater than Last\_Index (Container), at position Last\_Index (Container). It proceeds towards First\_Index (Container). If no equal element is found, then Reverse\_Find\_Index returns No\_Index. Otherwise, it returns the index of the first equal element encountered.
- 221/2     **function** Reverse\_Find (Container : Vector;  
                               Item        : Element\_Type;  
                               Position    : Cursor := No\_Element)  
       **return** Cursor;
- 222/3     {AI95-00302-03} {AI05-0264-1} If Position is not No\_Element, and does not designate an element in Container, then Program\_Error is propagated. Otherwise, Reverse\_Find searches the elements of Container for an element equal to Item (using the generic formal equality operator). The search starts at the last element if Position equals No\_Element, and at the element designated by Position otherwise. It proceeds towards the first element of Container. If no equal element is found, then Reverse\_Find returns No\_Element. Otherwise, it returns a cursor designating the first equal element encountered.
- 223/2     **function** Contains (Container : Vector;  
                           Item        : Element\_Type) **return** Boolean;
- 224/2     {AI95-00302-03} Equivalent to Has\_Element (Find (Container, Item)).
- Paragraphs 225 and 226 were moved above.*
- 227/2     **procedure** Iterate  
           (Container : **in** Vector;  
           Process    : **not null access procedure** (Position : **in** Cursor));
- 228/3     {AI95-00302-03} {AI05-0265-1} Invokes Process.all with a cursor that designates each element in Container, in index order. Tampering with the cursors of Container is prohibited during the execution of a call on Process.all. Any exception raised by Process.all is propagated.
- 228.a/2     **Discussion:** The purpose of the “tamper with the cursors” check is to prevent erroneous execution from the Position parameter of Process.all becoming invalid. This check takes place when the operations that tamper with the cursors of the container are called. The check cannot be made later (say in the body of Iterate), because that could cause the Position cursor to be invalid and potentially cause execution to become erroneous -- defeating the purpose of the check.
- 228.b/2     There is no check needed if an attempt is made to insert or delete nothing (that is, Count = 0 or Length(Item) = 0).
- 228.c/2     The check is easy to implement: each container needs a counter. The counter is incremented when Iterate is called, and decremented when Iterate completes. If the counter is nonzero when an operation that inserts or deletes is called, Finalize is called, or one of the other operations in the list occurs, Program\_Error is raised.
- 229/2     **procedure** Reverse\_Iterate  
           (Container : **in** Vector;  
           Process    : **not null access procedure** (Position : **in** Cursor));
- 230/3     {AI95-00302-03} {AI05-0212-1} Iterates over the elements in Container as per procedure Iterate, except that elements are traversed in reverse index order.
- 230.1/3     **function** Iterate (Container : **in** Vector)  
       **return** Vector\_Iterator\_Interfaces.Reversible\_Iterator'Class;
- 230.2/3     {AI05-0212-1} {AI05-0265-1} {AI05-0269-1} Iterate returns a reversible iterator object (see 5.5.1) that will generate a value for a loop parameter (see 5.5.2) designating each node in Container, starting with the first node and moving the cursor as per the Next function when used

|                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |         |

|                                           | in the body of the loop (assuming that Cur is the loop parameter and Stop is the cursor that you want to stop at).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | 230.c/3 |
| <i>{AI05-0044-1}</i> <i>{AI05-0262-1}</i> | The actual function for the generic formal function "<" of Generic_Sorting is expected to return the same value each time it is called with a particular pair of element values. It should define a strict weak ordering relationship (see A.18); it should not modify Container. If the actual for "<" behaves in some other manner, the behavior of the subprograms of Generic_Sorting are unspecified. The number of times the subprograms of Generic_Sorting call "<" is unspecified.                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 231/3   |
| <b>function</b>                           | <code>Is_Sorted (Container : Vector) return Boolean;</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | 232/2   |
|                                           | <i>{AI95-00302-03}</i> Returns True if the elements are sorted smallest first as determined by the generic formal "<" operator; otherwise, Is_Sorted returns False. Any exception raised during evaluation of "<" is propagated.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | 233/2   |
| <b>procedure</b>                          | <code>Sort (Container : in out Vector);</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | 234/2   |
|                                           | <i>{AI95-00302-03}</i> Reorders the elements of Container such that the elements are sorted smallest first as determined by the generic formal "<" operator provided. Any exception raised during evaluation of "<" is propagated.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | 235/2   |
|                                           | <b>Ramification:</b> This implies swapping the elements, usually including an intermediate copy. This means that the elements will usually be copied. (As with Swap, if the implementation can do this some other way, it is allowed to.) Since the elements are nonlimited, this usually will not be a problem. Note that there is Implementation Advice below that the implementation should use a sort that minimizes copying of elements.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | 235.a/2 |
|                                           | The sort is not required to be stable (and the fast algorithm required will not be stable). If a stable sort is needed, the user can include the original location of the element as an extra "sort key". We considered requiring the implementation to do that, but it is mostly extra overhead -- usually there is something already in the element that provides the needed stability.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 235.b/2 |
| <b>procedure</b>                          | <code>Merge (Target : in out Vector;<br/>Source : in out Vector);</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 236/2   |
|                                           | <i>{AI95-00302-03}</i> <i>{AI05-0021-1}</i> If Source is empty, then Merge does nothing. If Source and Target are the same nonempty container object, then Program_Error is propagated. Otherwise, Merge removes elements from Source and inserts them into Target; afterwards, Target contains                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | 237/3   |

the union of the elements that were initially in Source and Target; Source is left empty. If Target and Source are initially sorted smallest first, then Target is ordered smallest first as determined by the generic formal "<" operator; otherwise, the order of elements in Target is unspecified. Any exception raised during evaluation of "<" is propagated.

237.a/2 **Discussion:** It is a bounded error if either of the vectors is unsorted, see below. The bounded error can be recovered by sorting Target after the merge call, or the vectors can be pretested with Is\_Sorted.

237.b/2 **Implementation Note:** The Merge operation will usually require copying almost all of the elements. One implementation strategy would be to extend Target to the appropriate length, then copying elements from the back of the vectors working towards the front. An alternative approach would be to allocate a new internal data array of the appropriate length, copy the elements into it in an appropriate order, and then replacing the data array in Target with the temporary.

*Bounded (Run-Time) Errors*

238/3 {AI95-00302-03} {AI05-0212-1} Reading the value of an empty element by calling Element, Query\_Element, Update\_Element, Constant\_Reference, Reference, Swap, Is\_Sorted, Sort, Merge, "=", Find, or Reverse\_Find is a bounded error. The implementation may treat the element as having any normal value (see 13.9.1) of the element type, or raise Constraint\_Error or Program\_Error before modifying the vector.

238.a/2 **Ramification:** For instance, a default initialized element could be returned. Or some previous value of an element. But returning random junk is not allowed if the type has default initial value(s).

238.b/2 Assignment and streaming of empty elements are **not** bounded errors. This is consistent with regular composite types, for which assignment and streaming of uninitialized components do not cause a bounded error, but reading the uninitialized component does cause a bounded error.

238.c/2 There are other operations which are defined in terms of the operations listed above.

239/2 {AI95-00302-03} Calling Merge in an instance of Generic\_Sorting with either Source or Target not ordered smallest first using the provided generic formal "<" operator is a bounded error. Either Program\_Error is raised after Target is updated as described for Merge, or the operation works as defined.

239.1/3 {AI05-0022-1} {AI05-0248-1} It is a bounded error for the actual function associated with a generic formal subprogram, when called as part of an operation of this package, to tamper with elements of any Vector parameter of the operation. Either Program\_Error is raised, or the operation works as defined on the value of the Vector either prior to, or subsequent to, some or all of the modifications to the Vector.

239.2/3 {AI05-0027-1} It is a bounded error to call any subprogram declared in the visible part of Containers.Vectors when the associated container has been finalized. If the operation takes Container as an **in out** parameter, then it raises Constraint\_Error or Program\_Error. Otherwise, the operation either proceeds as it would for an empty container, or it raises Constraint\_Error or Program\_Error.

240/2 {AI95-00302-03} A Cursor value is *ambiguous* if any of the following have occurred since it was created:

241/2

- Insert, Insert\_Space, or Delete has been called on the vector that contains the element the cursor designates with an index value (or a cursor designating an element at such an index value) less than or equal to the index value of the element designated by the cursor; or

242/2

- The vector that contains the element it designates has been passed to the Sort or Merge procedures of an instance of Generic\_Sorting, or to the Reverse\_Elements procedure.

243/2 {AI95-00302-03} It is a bounded error to call any subprogram other than "=" or Has\_Element declared in Containers.Vectors with an ambiguous (but not invalid, see below) cursor parameter. Possible results are:

244/2

- The cursor may be treated as if it were No\_Element;

245/2

- The cursor may designate some element in the vector (but not necessarily the element that it originally designated);

246/2

- Constraint\_Error may be raised; or

- Program\_Error may be raised. 247/2
  - Reason:** Cursors are made ambiguous if an Insert or Delete occurs that moves the elements in the internal array including the designated ones. After such an operation, the cursor probably still designates an element (although it might not after a deletion), but it is a *different* element. That violates the definition of cursor — it designates a particular element. 247.a/2
  - For "=" or Has\_Element, the cursor works normally (it would not be No\_Element). We don't want to trigger an exception simply for comparing a bad cursor. 247.b/2
  - While it is possible to check for these cases or ensure that cursors survive such operations, in many cases the overhead necessary to make the check (or ensure cursors continue to designate the same element) is substantial in time or space. 247.c/2

*Erroneous Execution*

- {AI95-00302-03} A Cursor value is *invalid* if any of the following have occurred since it was created: 248/2
- The vector that contains the element it designates has been finalized; 249/2
  - {AI05-0160-1} The vector that contains the element it designates has been used as the Target of a call to Assign, or as the target of an `assignment_statement`; 249.1/3
  - [The vector that contains the element it designates has been used as the Source or Target of a call to Move;] or 250/2
    - Proof:** {AI05-0001-1} Move has been reworded in terms of Assign and Clear, which are covered by other bullets, so this text is redundant. 250.a/3
  - {AI05-0160-1} {AI05-0262-1} The element it designates has been deleted or removed from the vector that previously contained the element. 251/3
    - Ramification:** {AI05-0160-1} An element can be removed via calls to Set\_Length, Clear, and Merge; and indirectly via calls to Assign and Move. 251.a/3
- {AI95-00302-03} The result of "=" or Has\_Element is unspecified if it is called with an invalid cursor parameter. Execution is erroneous if any other subprogram declared in Containers.Vectors is called with an invalid cursor parameter. 252/2

**Discussion:** The list above (combined with the bounded error cases) is intended to be exhaustive. In other cases, a cursor value continues to designate its original element. For instance, cursor values survive the appending of new elements. 252.a/2

{AI05-0212-1} Execution is erroneous if the vector associated with the result of a call to Reference or Constant\_Reference is finalized before the result object returned by the call to Reference or Constant\_Reference is finalized. 252.1/3

**Reason:** Each object of Reference\_Type and Constant\_Reference\_Type probably contains some reference to the originating container. If that container is prematurely finalized (which is only possible via Unchecked\_Deallocation, as accessibility checks prevent passing a container to Reference that will not live as long as the result), the finalization of the object of Reference\_Type will try to access a nonexistent object. This is a normal case of a dangling pointer created by Unchecked\_Deallocation; we have to explicitly mention it here as the pointer in question is not visible in the specification of the type. (This is the same reason we have to say this for invalid cursors.) 252.b/3

*Implementation Requirements*

- {AI95-00302-03} No storage associated with a vector object shall be lost upon assignment or scope exit. 253/2
- {AI95-00302-03} {AI05-0262-1} The execution of an `assignment_statement` for a vector shall have the effect of copying the elements from the source vector object to the target vector object and changing the length of the target object to that of the source object. 254/3
- Implementation Note:** {AI05-0298-1} An assignment of a Vector is a “deep” copy; that is the elements are copied as well as the data structures. We say “effect of” in order to allow the implementation to avoid copying elements immediately if it wishes. For instance, an implementation that avoided copying until one of the containers is modified would be allowed. (Note that such an implementation would be require care, as Query\_Element and Constant\_Reference both could be used to access an element which later needs to be reallocated while the parameter or reference still exists, potentially leaving the parameter or reference pointing at the wrong element.) 254.a/3

*Implementation Advice*

- 255/2 {AI95-00302-03} Containers.Vectors should be implemented similarly to an array. In particular, if the length of a vector is  $N$ , then
- 256/2 • the worst-case time complexity of Element should be  $O(\log N)$ ;
- 256.a/2 **Implementation Advice:** The worst-case time complexity of Element for Containers.Vector should be  $O(\log N)$ .
- 257/2 • the worst-case time complexity of Append with Count=1 when  $N$  is less than the capacity of the vector should be  $O(\log N)$ ; and
- 257.a/2 **Implementation Advice:** The worst-case time complexity of Append with Count = 1 when  $N$  is less than the capacity for Containers.Vector should be  $O(\log N)$ .
- 258/2 • the worst-case time complexity of Prepend with Count=1 and Delete\_First with Count=1 should be  $O(N \log N)$ .
- 258.a/2 **Implementation Advice:** The worst-case time complexity of Prepend with Count = 1 and Delete\_First with Count=1 for Containers.Vectors should be  $O(N \log N)$ .
- 258.b/2 **Reason:** We do not mean to overly constrain implementation strategies here. However, it is important for portability that the performance of large containers has roughly the same factors on different implementations. If a program is moved to an implementation that takes  $O(N)$  time to access elements, that program could be unusable when the vectors are large. We allow  $O(\log N)$  access because the proportionality constant and caching effects are likely to be larger than the log factor, and we don't want to discourage innovative implementations.
- 259/2 {AI95-00302-03} The worst-case time complexity of a call on procedure Sort of an instance of Containers.Vectors.Generic\_Sorting should be  $O(N^{**2})$ , and the average time complexity should be better than  $O(N^{**2})$ .
- 259.a/2 **Implementation Advice:** The worst-case time complexity of a call on procedure Sort of an instance of Containers.Vectors.Generic\_Sorting should be  $O(N^{**2})$ , and the average time complexity should be better than  $O(N^{**2})$ .
- 259.b/2 **Ramification:** In other words, we're requiring the use of a better than  $O(N^{**2})$  sorting algorithm, such as Quicksort. No bubble sorts allowed!
- 260/2 {AI95-00302-03} Containers.Vectors.Generic\_Sorting.Sort and Containers.Vectors.Generic\_Sorting.Merge should minimize copying of elements.
- 260.a/2 **Implementation Advice:** Containers.Vectors.Generic\_Sorting.Sort and Containers.Vectors.Generic\_Sorting.Merge should minimize copying of elements.
- 260.b/2 **To be honest:** We do not mean “absolutely minimize” here; we're not intending to require a single copy for each element. Rather, we want to suggest that the sorting algorithm chosen is one that does not copy items unnecessarily. Bubble sort would not meet this advice, for instance.
- 261/2 {AI95-00302-03} Move should not copy elements, and should minimize copying of internal data structures.
- 261.a/2 **Implementation Advice:** Containers.Vectors.Move should not copy elements, and should minimize copying of internal data structures.
- 261.b/2 **Implementation Note:** Usually that can be accomplished simply by moving the pointer(s) to the internal data structures from the Source vector to the Target vector.
- 262/2 {AI95-00302-03} If an exception is propagated from a vector operation, no storage should be lost, nor any elements removed from a vector unless specified by the operation.
- 262.a/2 **Implementation Advice:** If an exception is propagated from a vector operation, no storage should be lost, nor any elements removed from a vector unless specified by the operation.
- 262.b/2 **Reason:** This is important so that programs can recover from errors. But we don't want to require heroic efforts, so we just require documentation of cases where this can't be accomplished.
- NOTES
- 263/2 48 All elements of a vector occupy locations in the internal array. If a sparse container is required, a Hashed\_Map should be used rather than a vector.

|    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |         |

| 49 | If <code>Index_Type'Base'First = Index_Type'First</code> an instance of <code>Ada.Containers.Vectors</code> will raise <code>Constraint_Error</code> . A value below <code>Index_Type'First</code> is required so that an empty vector has a meaningful value of <code>Last_Index</code> .                                                                                                                                                                                                                                                                 | 264/2   |
|    | <b>Discussion:</b> This property is the main reason why only integer types (as opposed to any discrete type) are allowed as the index type of a vector. An enumeration or modular type would require a subtype in order to meet this requirement.                                                                                                                                                                                                                                                                                                          | 264.a/2 |

|    | {AI95-00302-03} The package <code>Containers.Vectors</code> is new.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | 264.b/2 |
|    | <i>Incompatibilities With Ada 2005</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |         |
|    | {AI05-0001-1} Subprograms <code>Assign</code> and <code>Copy</code> are added to <code>Containers.Vectors</code> . If an instance of <code>Containers.Vectors</code> is referenced in a <code>use_clause</code> , and an entity <i>E</i> with the same <code>defining_identifier</code> as a new entity in <code>Containers.Vectors</code> is defined in a package that is also referenced in a <code>use_clause</code> , the entity <i>E</i> may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur. | 264.c/3 |
|    | <i>Extensions to Ada 2005</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |         |
|    | {AI05-0212-1} Added iterator, reference, and indexing support to make vector containers more convenient to use.                                                                                                                                                                                                                                                                                                                                                                                                                                            | 264.d/3 |
|    | <i>Wording Changes from Ada 2005</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |         |
|    | {AI05-0001-1} Generalized the definition of <code>Reserve_Capacity</code> and <code>Move</code> . Specified which elements are read/written by stream attributes.                                                                                                                                                                                                                                                                                                                                                                                          | 264.e/3 |
|    | {AI05-0022-1} <b>Correction:</b> Added a Bounded (Run-Time) Error to cover tampering by generic actual subprograms.                                                                                                                                                                                                                                                                                                                                                                                                                                        | 264.f/3 |
|    | {AI05-0027-1} <b>Correction:</b> Added a Bounded (Run-Time) Error to cover access to finalized vector containers.                                                                                                                                                                                                                                                                                                                                                                                                                                          | 264.g/3 |
|    | {AI05-0044-1} <b>Correction:</b> Redefined " <code>&lt;</code> " actuals to require a strict weak ordering; the old definition allowed indeterminant comparisons that would not have worked in a container.                                                                                                                                                                                                                                                                                                                                                | 264.h/3 |
|    | {AI05-0084-1} <b>Correction:</b> Added a pragma <code>Remote_Types</code> so that containers can be used in distributed programs.                                                                                                                                                                                                                                                                                                                                                                                                                          | 264.i/3 |
|    | {AI05-0160-1} <b>Correction:</b> Revised the definition of invalid cursors to cover missing (and new) cases.                                                                                                                                                                                                                                                                                                                                                                                                                                               | 264.j/3 |
|    | {AI05-0265-1} <b>Correction:</b> Defined when a container prohibits tampering in order to more clearly define where the check is made and the exception raised.                                                                                                                                                                                                                                                                                                                                                                                            | 264.k/3 |

### A.18.3 The Generic Package `Containers.Doubly_Linked_Lists`

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |     |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| {AI95-00302-03} | The language-defined generic package <code>Containers.Doubly_Linked_Lists</code> provides private types <code>List</code> and <code>Cursor</code> , and a set of operations for each type. A list container is optimized for insertion and deletion at any position.                                                                                                                                                                                                 | 1/2 |
| {AI95-00302-03} | A doubly-linked list container object manages a linked list of internal <i>nodes</i> , each of which contains an element and pointers to the next (successor) and previous (predecessor) internal nodes. A cursor designates a particular node within a list (and by extension the element contained in that node). A cursor keeps designating the same node (and element) as long as the node is part of the container, even if the node is moved in the container. | 2/2 |
| {AI95-00302-03} | The <i>length</i> of a list is the number of elements it contains.                                                                                                                                                                                                                                                                                                                                                                                                   | 3/2 |

#### *Static Semantics*

|                             |                                                                                                                                                                                                                                                                                                         |     |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|

55/2 {AI95-00302-03} The actual function for the generic formal function "=" on Element\_Type values is expected to define a reflexive and symmetric relationship and return the same result value each time it is called with a particular pair of values. If it behaves in some other manner, the functions Find, Reverse\_Find, and "=" on list values return an unspecified value. The exact arguments and number of calls of this generic formal function by the functions Find, Reverse\_Find, and "=" on list values are unspecified.

55.a/2 **Ramification:** If the actual function for "=" is not symmetric and consistent, the result returned by the listed functions cannot be predicted. The implementation is not required to protect against "=" raising an exception, or returning random results, or any other "bad" behavior. And it can call "=" in whatever manner makes sense. But note that only the results of Find, Reverse\_Find, and List "=" are unspecified; other subprograms are not allowed to break if "=" is bad (they aren't expected to use "=").

56/2 {AI95-00302-03} The type List is used to represent lists. The type List needs finalization (see 7.6).

57/2 {AI95-00302-03} Empty\_List represents the empty List object. It has a length of 0. If an object of type List is not otherwise initialized, it is initialized to the same value as Empty\_List.

58/2 {AI95-00302-03} No\_Element represents a cursor that designates no element. If an object of type Cursor is not otherwise initialized, it is initialized to the same value as No\_Element.

59/2 {AI95-00302-03} The predefined "=" operator for type Cursor returns True if both cursors are No\_Element, or designate the same element in the same container.

60/2 {AI95-00302-03} Execution of the default implementation of the Input, Output, Read, or Write attribute of type Cursor raises Program\_Error.

60.a/2 **Reason:** A cursor will probably be implemented in terms of one or more access values, and the effects of streaming access values is unspecified. Rather than letting the user stream junk by accident, we mandate that streaming of cursors raise Program\_Error by default. The attributes can always be specified if there is a need to support streaming.

60.1/3 {AI05-0001-1} {AI05-0262-1} List'Write for a List object *L* writes Length(*L*) elements of the list to the stream. It also may write additional information about the list.

60.2/3 {AI05-0001-1} {AI05-0262-1} List'Read reads the representation of a list from the stream, and assigns to *Item* a list with the same length and elements as was written by List'Write.

- Ramification:** Streaming more elements than the container length is wrong. For implementation implications of this rule, see the Implementation Note in A.18.2. 60.b/3
- {AI95-00302-03} [Some operations of this generic package have access-to-subprogram parameters. To ensure such operations are well-defined, they guard against certain actions by the designated subprogram. In particular, some operations check for “tampering with cursors” of a container because they depend on the set of elements of the container remaining constant, and others check for “tampering with elements” of a container because they depend on elements of the container not being replaced.] 61/2
- {AI95-00302-03} A subprogram is said to *tamper with cursors* of a list object *L* if: 62/2
- it inserts or deletes elements of *L*, that is, it calls the `Insert`, `Clear`, `Delete`, or `Delete_Last` procedures with *L* as a parameter; or 63/2
    - To be honest:** Operations which are defined to be equivalent to a call on one of these operations also are included. Similarly, operations which call one of these as part of their definition are included. 63.a/2
  - it reorders the elements of *L*, that is, it calls the `Splice`, `Swap_Links`, or `Reverse_Elements` procedures or the `Sort` or `Merge` procedures of an instance of `Generic_Sorting` with *L* as a parameter; or 64/2
  - it finalizes *L*; or 65/2
  - {AI05-0001-1} it calls the `Assign` procedure with *L* as the `Target` parameter; or 65.1/3
    - Ramification:** We don't need to explicitly mention `assignment_statement`, because that finalizes the target object as part of the operation, and finalization of an object is already defined as tampering with cursors. 65.a.1/3
  - it calls the `Move` procedure with *L* as a parameter. 66/2
    - Reason:** Swap copies elements rather than reordering them, so it doesn't tamper with cursors. 66.a/2
- {AI95-00302-03} A subprogram is said to *tamper with elements* of a list object *L* if: 67/2
- it tampers with cursors of *L*; or 68/2
  - it replaces one or more elements of *L*, that is, it calls the `Replace_Element` or `Swap` procedures with *L* as a parameter. 69/2
    - Reason:** Complete replacement of an element can cause its memory to be deallocated while another operation is holding onto a reference to it. That can't be allowed. However, a simple modification of (part of) an element is not a problem, so `Update_Element` does not cause a problem. 69.a/2
- {AI05-0265-1} When tampering with cursors is *prohibited* for a particular list object *L*, `Program_Error` is propagated by a call of any language-defined subprogram that is defined to tamper with the cursors of *L*, leaving *L* unmodified. Similarly, when tampering with elements is *prohibited* for a particular list object *L*, `Program_Error` is propagated by a call of any language-defined subprogram that is defined to tamper with the elements of *L* [(or tamper with the cursors of *L*)], leaving *L* unmodified. 69.1/3
- Proof:** Tampering with elements includes tampering with cursors, so we mention it only from completeness in the second sentence. 69.b/3
- function** `Has_Element` (`Position` : `Cursor`) **return** `Boolean`; 69.2/3
- {AI05-0212-1} Returns `True` if `Position` designates an element, and returns `False` otherwise. 69.3/3
- To be honest:** {AI05-0005-1} {AI05-0212-1} This function might not detect cursors that designate deleted elements; such cursors are invalid (see below) and the result of calling `Has_Element` with an invalid cursor is unspecified (but not erroneous). 69.c/3
- function** `"="` (`Left`, `Right` : `List`) **return** `Boolean`; 70/2
- {AI95-00302-03} {AI05-0264-1} If `Left` and `Right` denote the same list object, then the function returns `True`. If `Left` and `Right` have different lengths, then the function returns `False`. Otherwise, it compares each element in `Left` to the corresponding element in `Right` using the generic formal equality operator. If any such comparison returns `False`, the function returns `False`; otherwise, it returns `True`. Any exception raised during evaluation of element equality is propagated. 71/3

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |         |

| <i>{AI05-0212-1}</i> The types Constant_Reference_Type and Reference_Type need finalization.                                                                                                                                                                                                                                                                                                                                                                                                | 86.3/3  |
| The default initialization of an object of type Constant_Reference_Type or Reference_Type propagates Program_Error.                                                                                                                                                                                                                                                                                                                                                                         | 86.4/3  |
| <b>Reason:</b> It is expected that Reference_Type (and Constant_Reference_Type) will be a controlled type, for which finalization will have some action to terminate the tampering check for the associated container. If the object is created by default, however, there is no associated container. Since this is useless, and supporting this case would take extra work, we define it to raise an exception.                                                                           | 86.b/3  |
| <b>function</b> Constant_Reference (Container : <b>aliased in</b> List;<br>Position : <b>in</b> Cursor)<br><b>return</b> Constant_Reference_Type;                                                                                                                                                                                                                                                                                                                                           | 86.5/3  |
| <i>{AI05-0212-1}</i> <i>{AI05-0269-1}</i> This function (combined with the Constant_Indexing and Implicit_Dereference aspects) provides a convenient way to gain read access to an individual element of a list given a cursor.                                                                                                                                                                                                                                                             | 86.6/3  |
| <i>{AI05-0212-1}</i> <i>{AI05-0265-1}</i> If Position equals No_Element, then Constraint_Error is propagated; if Position does not designate an element in Container, then Program_Error is propagated. Otherwise, Constant_Reference returns an object whose discriminant is an access value that designates the element designated by Position. Tampering with the elements of Container is prohibited while the object returned by Constant_Reference exists and has not been finalized. | 86.7/3  |
| <b>function</b> Reference (Container : <b>aliased in out</b> List;<br>Position : <b>in</b> Cursor)<br><b>return</b> Reference_Type;                                                                                                                                                                                                                                                                                                                                                         | 86.8/3  |
| <i>{AI05-0212-1}</i> <i>{AI05-0269-1}</i> This function (combined with the Variable_Indexing and Implicit_Dereference aspects) provides a convenient way to gain read and write access to an individual element of a list given a cursor.                                                                                                                                                                                                                                                   | 86.9/3  |
| <i>{AI05-0212-1}</i> <i>{AI05-0265-1}</i> If Position equals No_Element, then Constraint_Error is propagated; if Position does not designate an element in Container, then Program_Error is propagated. Otherwise, Reference returns an object whose discriminant is an access value that designates the element designated by Position. Tampering with the elements of Container is prohibited while the object returned by Reference exists and has not been finalized.                   | 86.10/3 |
| <b>procedure</b> Assign (Target : <b>in out</b> List; Source : <b>in</b> List);                                                                                                                                                                                                                                                                                                                                                                                                             | 86.11/3 |
| <i>{AI05-0001-1}</i> <i>{AI05-0248-1}</i> If Target denotes the same object as Source, the operation has no effect. Otherwise, the elements of Source are copied to Target as for an <b>assignment_statement</b> assigning Source to Target.                                                                                                                                                                                                                                                | 86.12/3 |
| <b>Discussion:</b> <i>{AI05-0005-1}</i> This routine exists for compatibility with the bounded list container. For an unbounded list, Assign(A, B) and A := B behave identically. For a bounded list, := will raise an exception if the container capacities are different, while Assign will not raise an exception if there is enough room in the target.                                                                                                                                 | 86.c/3  |

- 89/2       **procedure** Insert (Container : **in out** List;  
                   Before     : **in**     Cursor;  
                   New\_Item   : **in**     Element\_Type;  
                   Count     : **in**     Count\_Type := 1);
- 90/2       {AI95-00302-03} If Before is not No\_Element, and does not designate an element in Container, then Program\_Error is propagated. Otherwise, Insert inserts Count copies of New\_Item prior to the element designated by Before. If Before equals No\_Element, the new elements are inserted after the last node (if any). Any exception raised during allocation of internal storage is propagated, and Container is not modified.
- 90.a/2     **Ramification:** The check on Before checks that the cursor does not belong to some other Container. This check implies that a reference to the container is included in the cursor value. This wording is not meant to require detection of dangling cursors; such cursors are defined to be invalid, which means that execution is erroneous, and any result is allowed (including not raising an exception).
- 91/2       **procedure** Insert (Container : **in out** List;  
                   Before     : **in**     Cursor;  
                   New\_Item   : **in**     Element\_Type;  
                   Position   :     **out** Cursor;  
                   Count     : **in**     Count\_Type := 1);
- 92/3       {AI95-00302-03} {AI05-0257-1} If Before is not No\_Element, and does not designate an element in Container, then Program\_Error is propagated. Otherwise, Insert allocates Count copies of New\_Item, and inserts them prior to the element designated by Before. If Before equals No\_Element, the new elements are inserted after the last element (if any). Position designates the first newly-inserted element, or if Count equals 0, then Position is assigned the value of Before. Any exception raised during allocation of internal storage is propagated, and Container is not modified.
- 93/2       **procedure** Insert (Container : **in out** List;  
                   Before     : **in**     Cursor;  
                   Position   :     **out** Cursor;  
                   Count     : **in**     Count\_Type := 1);
- 94/3       {AI95-00302-03} {AI05-0257-1} If Before is not No\_Element, and does not designate an element in Container, then Program\_Error is propagated. Otherwise, Insert inserts Count new elements prior to the element designated by Before. If Before equals No\_Element, the new elements are inserted after the last node (if any). The new elements are initialized by default (see 3.3.1). Position designates the first newly-inserted element, or if Count equals 0, then Position is assigned the value of Before. Any exception raised during allocation of internal storage is propagated, and Container is not modified.
- 95/2       **procedure** Prepend (Container : **in out** List;  
                   New\_Item   : **in**     Element\_Type;  
                   Count     : **in**     Count\_Type := 1);
- 96/2       {AI95-00302-03} Equivalent to Insert (Container, First (Container), New\_Item, Count).
- 97/2       **procedure** Append (Container : **in out** List;  
                   New\_Item   : **in**     Element\_Type;  
                   Count     : **in**     Count\_Type := 1);
- 98/2       {AI95-00302-03} Equivalent to Insert (Container, No\_Element, New\_Item, Count).
- 99/2       **procedure** Delete (Container : **in out** List;  
                   Position   : **in out** Cursor;  
                   Count     : **in**     Count\_Type := 1);
- 100/3      {AI95-00302-03} {AI05-0264-1} If Position equals No\_Element, then Constraint\_Error is propagated. If Position does not designate an element in Container, then Program\_Error is propagated. Otherwise, Delete removes (from Container) Count elements starting at the element

- designated by Position (or all of the elements starting at Position if there are fewer than Count elements starting at Position). Finally, Position is set to No\_Element.
- procedure** Delete\_First (Container : in out List; 101/2  
Count : in Count\_Type := 1);
- {AI95-00302-03} {AI05-0021-1} If Length (Container) <= Count, then Delete\_First is equivalent 102/3  
to Clear (Container). Otherwise, it removes the first Count nodes from Container.
- procedure** Delete\_Last (Container : in out List; 103/2  
Count : in Count\_Type := 1);
- {AI95-00302-03} {AI05-0264-1} If Length (Container) <= Count, then Delete\_Last is equivalent 104/3  
to Clear (Container). Otherwise, it removes the last Count nodes from Container.
- procedure** Reverse\_Elements (Container : in out List); 105/2
- {AI95-00302-03} Reorders the elements of Container in reverse order. 106/2
- Discussion:** Unlike the similar routine for a vector, elements should not be copied; rather, the nodes should be 106.a/2  
exchanged. Cursors are expected to reference the same elements afterwards.
- procedure** Swap (Container : in out List; 107/2  
I, J : in Cursor);
- {AI95-00302-03} If either I or J is No\_Element, then Constraint\_Error is propagated. If either I 108/2  
or J do not designate an element in Container, then Program\_Error is propagated. Otherwise,  
Swap exchanges the values of the elements designated by I and J.
- Ramification:** After a call to Swap, I designates the element value previously designated by J, and J designates the 108.a/2  
element value previously designated by I. The cursors do not become ambiguous from this operation.
- To be honest:** The implementation is not required to actually copy the elements if it can do the swap some other way. 108.b/2  
But it is allowed to copy the elements if needed.
- procedure** Swap\_Links (Container : in out List; 109/2  
I, J : in Cursor);
- {AI95-00302-03} If either I or J is No\_Element, then Constraint\_Error is propagated. If either I 110/2  
or J do not designate an element in Container, then Program\_Error is propagated. Otherwise,  
Swap\_Links exchanges the nodes designated by I and J.
- Ramification:** Unlike Swap, this exchanges the nodes, not the elements. No copying is performed. I and J designate 110.a/2  
the same elements after this call as they did before it. This operation can provide better performance than Swap if the  
element size is large.
- procedure** Splice (Target : in out List; 111/2  
Before : in Cursor;  
Source : in out List);
- {AI95-00302-03} If Before is not No\_Element, and does not designate an element in Target, then 112/2  
Program\_Error is propagated. Otherwise, if Source denotes the same object as Target, the  
operation has no effect. Otherwise, Splice reorders elements such that they are removed from  
Source and moved to Target, immediately prior to Before. If Before equals No\_Element, the  
nodes of Source are spliced after the last node of Target. The length of Target is incremented by  
the number of nodes in Source, and the length of Source is set to 0.
- procedure** Splice (Target : in out List; 113/2  
Before : in Cursor;  
Source : in out List;  
Position : in out Cursor);
- {AI95-00302-03} {AI05-0264-1} If Position is No\_Element, then Constraint\_Error is propagated. 114/3  
If Before does not equal No\_Element, and does not designate an element in Target, then  
Program\_Error is propagated. If Position does not equal No\_Element, and does not designate a

node in Source, then Program\_Error is propagated. If Source denotes the same object as Target, then there is no effect if Position equals Before, else the element designated by Position is moved immediately prior to Before, or, if Before equals No\_Element, after the last element. In both cases, Position and the length of Target are unchanged. Otherwise, the element designated by Position is removed from Source and moved to Target, immediately prior to Before, or, if Before equals No\_Element, after the last element of Target. The length of Target is incremented, the length of Source is decremented, and Position is updated to represent an element in Target.

114.a/2 **Ramification:** If Source is the same as Target, and Position = Before, or Next(Position) = Before, Splice has no effect, as the element does not have to move to meet the postcondition.

```
115/2 procedure Splice (Container: in out List;
 Before : in Cursor;
 Position : in Cursor);
```

116/3 {AI95-00302-03} {AI05-0264-1} If Position is No\_Element, then Constraint\_Error is propagated. If Before does not equal No\_Element, and does not designate an element in Container, then Program\_Error is propagated. If Position does not equal No\_Element, and does not designate a node in Container, then Program\_Error is propagated. If Position equals Before there is no effect. Otherwise, the element designated by Position is moved immediately prior to Before, or, if Before equals No\_Element, after the last element. The length of Container is unchanged.

```
117/2 function First (Container : List) return Cursor;
```

118/3 {AI95-00302-03} {AI05-0264-1} If Container is empty, First returns the value No\_Element. Otherwise, it returns a cursor that designates the first node in Container.

```
119/2 function First_Element (Container : List) return Element_Type;
```

120/2 {AI95-00302-03} Equivalent to Element (First (Container)).

```
121/2 function Last (Container : List) return Cursor;
```

122/3 {AI95-00302-03} {AI05-0264-1} If Container is empty, Last returns the value No\_Element. Otherwise, it returns a cursor that designates the last node in Container.

```
123/2 function Last_Element (Container : List) return Element_Type;
```

124/2 {AI95-00302-03} Equivalent to Element (Last (Container)).

```
125/2 function Next (Position : Cursor) return Cursor;
```

126/2 {AI95-00302-03} If Position equals No\_Element or designates the last element of the container, then Next returns the value No\_Element. Otherwise, it returns a cursor that designates the successor of the element designated by Position.

```
127/2 function Previous (Position : Cursor) return Cursor;
```

128/2 {AI95-00302-03} If Position equals No\_Element or designates the first element of the container, then Previous returns the value No\_Element. Otherwise, it returns a cursor that designates the predecessor of the element designated by Position.

```
129/2 procedure Next (Position : in out Cursor);
```

130/2 {AI95-00302-03} Equivalent to Position := Next (Position).

```
131/2 procedure Previous (Position : in out Cursor);
```

132/2 {AI95-00302-03} Equivalent to Position := Previous (Position).

- function** Find (Container : List; 133/2  
                   Item      : Element\_Type;  
                   Position  : Cursor := No\_Element)  
**return** Cursor;  
 {AI95-00302-03} If Position is not No\_Element, and does not designate an element in Container, 134/2  
 then Program\_Error is propagated. Find searches the elements of Container for an element equal  
 to Item (using the generic formal equality operator). The search starts at the element designated  
 by Position, or at the first element if Position equals No\_Element. It proceeds towards Last  
 (Container). If no equal element is found, then Find returns No\_Element. Otherwise, it returns a  
 cursor designating the first equal element encountered.
- function** Reverse\_Find (Container : List; 135/2  
                   Item      : Element\_Type;  
                   Position  : Cursor := No\_Element)  
**return** Cursor;  
 {AI95-00302-03} If Position is not No\_Element, and does not designate an element in Container, 136/2  
 then Program\_Error is propagated. Find searches the elements of Container for an element equal  
 to Item (using the generic formal equality operator). The search starts at the element designated  
 by Position, or at the last element if Position equals No\_Element. It proceeds towards First  
 (Container). If no equal element is found, then Reverse\_Find returns No\_Element. Otherwise, it  
 returns a cursor designating the first equal element encountered.
- function** Contains (Container : List; 137/2  
                   Item      : Element\_Type) **return** Boolean;  
 {AI95-00302-03} Equivalent to Find (Container, Item) /= No\_Element. 138/2
- Paragraphs 139 and 140 were moved above.*
- procedure** Iterate 141/2  
 (Container : **in** List;  
 Process   : **not null access procedure** (Position : **in** Cursor));  
 {AI95-00302-03} {AI05-0265-1} Iterate calls Process.all with a cursor that designates each node 142/3  
 in Container, starting with the first node and moving the cursor as per the Next function.  
 Tampering with the cursors of Container is prohibited during the execution of a call on  
 Process.all. Any exception raised by Process.all is propagated.
- Implementation Note:** The purpose of the tamper with cursors check is to prevent erroneous execution from the 142.a/2  
 Position parameter of Process.all becoming invalid. This check takes place when the operations that tamper with the  
 cursors of the container are called. The check cannot be made later (say in the body of Iterate), because that could  
 cause the Position cursor to be invalid and potentially cause execution to become erroneous -- defeating the purpose of  
 the check.
- See Iterate for vectors (A.18.2) for a suggested implementation of the check. 142.b/2
- procedure** Reverse\_Iterate 143/2  
 (Container : **in** List;  
 Process   : **not null access procedure** (Position : **in** Cursor));  
 {AI95-00302-03} {AI05-0212-1} Iterates over the nodes in Container as per procedure Iterate, 144/3  
 except that elements are traversed in reverse order, starting with the last node and moving the  
 cursor as per the Previous function.
- function** Iterate (Container : **in** List) 144.1/3  
**return** List\_Iterator\_Interfaces.Reversible\_Iterator'Class;  
 {AI05-0212-1} {AI05-0265-1} {AI05-0269-1} Iterate returns a reversible iterator object (see 144.2/3  
 5.5.1) that will generate a value for a loop parameter (see 5.5.2) designating each node in  
 Container, starting with the first node and moving the cursor as per the Next function when used  
 as a forward iterator, and starting with the last node and moving the cursor as per the Previous

function when used as a reverse iterator. Tampering with the cursors of Container is prohibited while the iterator object exists (in particular, in the `sequence_of_statements` of the `loop_statement` whose `iterator_specification` denotes this object). The iterator object needs finalization.

- 144.3/3 **function** Iterate (Container : **in** List; Start : **in** Cursor)  
**return** List\_Iterator\_Interfaces.Reversible\_Iterator'Class;
- 144.4/3 {AI05-0212-1} {AI05-0262-1} {AI05-0265-1} {AI05-0269-1} If Start is not No\_Element and does not designate an item in Container, then Program\_Error is propagated. If Start is No\_Element, then Constraint\_Error is propagated. Otherwise, Iterate returns a reversible iterator object (see 5.5.1) that will generate a value for a loop parameter (see 5.5.2) designating each node in Container, starting with the node designated by Start and moving the cursor as per the Next function when used as a forward iterator, or moving the cursor as per the Previous function when used as a reverse iterator. Tampering with the cursors of Container is prohibited while the iterator object exists (in particular, in the `sequence_of_statements` of the `loop_statement` whose `iterator_specification` denotes this object). The iterator object needs finalization.
- 144.a/3 **Discussion:** Exits are allowed from the loops created using the iterator objects. In particular, to stop the iteration at a particular cursor, just add
- 144.b/3 **exit when** Cur = Stop;
- 144.c/3 in the body of the loop (assuming that Cur is the loop parameter and Stop is the cursor that you want to stop at).
- 145/3 {AI05-0044-1} {AI05-0262-1} The actual function for the generic formal function "<" of Generic\_Sorting is expected to return the same value each time it is called with a particular pair of element values. It should define a strict weak ordering relationship (see A.18); it should not modify Container. If the actual for "<" behaves in some other manner, the behavior of the subprograms of Generic\_Sorting are unspecified. The number of times the subprograms of Generic\_Sorting call "<" is unspecified.
- 146/2 **function** Is\_Sorted (Container : List) **return** Boolean;
- 147/2 {AI95-00302-03} Returns True if the elements are sorted smallest first as determined by the generic formal "<" operator; otherwise, Is\_Sorted returns False. Any exception raised during evaluation of "<" is propagated.
- 148/2 **procedure** Sort (Container : **in out** List);
- 149/2 {AI95-00302-03} Reorders the nodes of Container such that the elements are sorted smallest first as determined by the generic formal "<" operator provided. The sort is stable. Any exception raised during evaluation of "<" is propagated.
- 149.a/2 **Ramification:** Unlike array sorts, we do require stable sorts here. That's because algorithms in the merge sort family (as described by Knuth) can be both fast and stable. Such sorts use the extra memory as offered by the links to provide better performance.
- 149.b/2 Note that list sorts never copy elements; it is the nodes, not the elements, that are reordered.
- 150/2 **procedure** Merge (Target : **in out** List;  
Source : **in out** List);
- 151/3 {AI95-00302-03} {AI05-0021-1} If Source is empty, then Merge does nothing. If Source and Target are the same nonempty container object, then Program\_Error is propagated. Otherwise, Merge removes elements from Source and inserts them into Target; afterwards, Target contains the union of the elements that were initially in Source and Target; Source is left empty. If Target and Source are initially sorted smallest first, then Target is ordered smallest first as determined by the generic formal "<" operator; otherwise, the order of elements in Target is unspecified. Any exception raised during evaluation of "<" is propagated.

**Ramification:** It is a bounded error if either of the lists is unsorted, see below. The bounded error can be recovered by sorting Target after the merge call, or the lists can be pretested with Is\_Sorted. 151.a/2

*Bounded (Run-Time) Errors*

{AI95-00302-03} Calling Merge in an instance of Generic\_Sorting with either Source or Target not ordered smallest first using the provided generic formal "<" operator is a bounded error. Either Program\_Error is raised after Target is updated as described for Merge, or the operation works as defined. 152/2

{AI05-0022-1} {AI05-0248-1} It is a bounded error for the actual function associated with a generic formal subprogram, when called as part of an operation of this package, to tamper with elements of any List parameter of the operation. Either Program\_Error is raised, or the operation works as defined on the value of the List either prior to, or subsequent to, some or all of the modifications to the List. 152.1/3

{AI05-0027-1} It is a bounded error to call any subprogram declared in the visible part of Containers.Doubly\_Linked\_Lists when the associated container has been finalized. If the operation takes Container as an **in out** parameter, then it raises Constraint\_Error or Program\_Error. Otherwise, the operation either proceeds as it would for an empty container, or it raises Constraint\_Error or Program\_Error. 152.2/3

*Erroneous Execution*

{AI95-00302-03} A Cursor value is *invalid* if any of the following have occurred since it was created: 153/2

- The list that contains the element it designates has been finalized; 154/2
- {AI05-0160-1} The list that contains the element it designates has been used as the Target of a call to Assign, or as the target of an **assignment\_statement**; 154.1/3
- [The list that contains the element it designates has been used as the Source or Target of a call to Move;] or 155/2

**Proof:** {AI05-0001-1} Move has been reworded in terms of Assign and Clear, which are covered by other bullets, so this text is redundant. 155.a/3

- {AI05-0160-1} {AI05-0262-1} The element it designates has been removed from the list that previously contained the element. 156/3

**To be honest:** {AI05-0160-1} The cursor modified by the four parameter Splice is not invalid, even though the element it designates has been removed from the source list, because that cursor has been modified to designate that element in the target list – the cursor no longer designates an element in the source list. 156.a/3

**Ramification:** {AI05-0160-1} This can happen directly via calls to Delete, Delete\_Last, Clear, Splice with a Source parameter, and Merge; and indirectly via calls to Delete\_First, Assign, and Move. 156.b/3

{AI95-00302-03} The result of "=" or Has\_Element is unspecified if it is called with an invalid cursor parameter. Execution is erroneous if any other subprogram declared in Containers.Doubly\_Linked\_Lists is called with an invalid cursor parameter. 157/2

**Discussion:** The list above is intended to be exhaustive. In other cases, a cursor value continues to designate its original element. For instance, cursor values survive the insertion and deletion of other nodes. 157.a/2

While it is possible to check for these cases, in many cases the overhead necessary to make the check is substantial in time or space. Implementations are encouraged to check for as many of these cases as possible and raise Program\_Error if detected. 157.b/2

{AI05-0212-1} Execution is erroneous if the list associated with the result of a call to Reference or Constant\_Reference is finalized before the result object returned by the call to Reference or Constant\_Reference is finalized. 157.1/3

**Reason:** Each object of Reference\_Type and Constant\_Reference\_Type probably contains some reference to the originating container. If that container is prematurely finalized (which is only possible via Unchecked\_Deallocation, as accessibility checks prevent passing a container to Reference that will not live as long as the result), the finalization of the object of Reference\_Type will try to access a nonexistent object. This is a normal case of a dangling pointer created 157.c/3

by `Unchecked_Deallocation`; we have to explicitly mention it here as the pointer in question is not visible in the specification of the type. (This is the same reason we have to say this for invalid cursors.)

*Implementation Requirements*

- 158/2 {AI95-00302-03} No storage associated with a doubly-linked List object shall be lost upon assignment or scope exit.
- 159/3 {AI95-00302-03} {AI05-0262-1} The execution of an `assignment_statement` for a list shall have the effect of copying the elements from the source list object to the target list object and changing the length of the target object to that of the source object.
- 159.a/3 **Implementation Note:** {AI05-0298-1} An assignment of a List is a “deep” copy; that is the elements are copied as well as the data structures. We say “effect of” in order to allow the implementation to avoid copying elements immediately if it wishes. For instance, an implementation that avoided copying until one of the containers is modified would be allowed. (Note that this implementation would require care, see A.18.2 for more.)

*Implementation Advice*

- 160/2 {AI95-00302-03} `Containers.Doubly_Linked_Lists` should be implemented similarly to a linked list. In particular, if  $N$  is the length of a list, then the worst-case time complexity of `Element`, `Insert` with `Count=1`, and `Delete` with `Count=1` should be  $O(\log N)$ .
- 160.a/2 **Implementation Advice:** The worst-case time complexity of `Element`, `Insert` with `Count=1`, and `Delete` with `Count=1` for `Containers.Doubly_Linked_Lists` should be  $O(\log N)$ .
- 160.b/2 **Reason:** We do not mean to overly constrain implementation strategies here. However, it is important for portability that the performance of large containers has roughly the same factors on different implementations. If a program is moved to an implementation that takes  $O(N)$  time to access elements, that program could be unusable when the lists are large. We allow  $O(\log N)$  access because the proportionality constant and caching effects are likely to be larger than the log factor, and we don't want to discourage innovative implementations.
- 161/2 {AI95-00302-03} The worst-case time complexity of a call on procedure `Sort` of an instance of `Containers.Doubly_Linked_Lists.Generic_Sorting` should be  $O(N^2)$ , and the average time complexity should be better than  $O(N^2)$ .
- 161.a/2 **Implementation Advice:** A call on procedure `Sort` of an instance of `Containers.Doubly_Linked_Lists.Generic_Sorting` should have an average time complexity better than  $O(N^2)$  and worst case no worse than  $O(N^2)$ .
- 161.b/2 **Ramification:** In other words, we're requiring the use of a better than  $O(N^2)$  sorting algorithm, such as Quicksort. No bubble sorts allowed!
- 162/2 {AI95-00302-03} `Move` should not copy elements, and should minimize copying of internal data structures.
- 162.a/2 **Implementation Advice:** `Containers.Doubly_Linked_Lists.Move` should not copy elements, and should minimize copying of internal data structures.
- 162.b/2 **Implementation Note:** Usually that can be accomplished simply by moving the pointer(s) to the internal data structures from the Source container to the Target container.
- 163/2 {AI95-00302-03} If an exception is propagated from a list operation, no storage should be lost, nor any elements removed from a list unless specified by the operation.
- 163.a/2 **Implementation Advice:** If an exception is propagated from a list operation, no storage should be lost, nor any elements removed from a list unless specified by the operation.
- 163.b/2 **Reason:** This is important so that programs can recover from errors. But we don't want to require heroic efforts, so we just require documentation of cases where this can't be accomplished.

NOTES

- 164/2 50 {AI95-00302-03} Sorting a list never copies elements, and is a stable sort (equal elements remain in the original order). This is different than sorting an array or vector, which may need to copy elements, and is probably not a stable sort.

*Extensions to Ada 95*

- 164.a/2 {AI95-00302-03} The generic package `Containers.Doubly_Linked_Lists` is new.

*Inconsistencies With Ada 2005*

{AI05-0248-1} {AI05-0257-1} **Correction:** The Insert versions that return a Position parameter are now defined to return Position = Before if Count = 0. This was unspecified for Ada 2005; so this will only be inconsistent if an implementation did something else and a program depended on that something else — this should be very rare. 164.b/3

*Incompatibilities With Ada 2005*

{AI05-0001-1} Subprograms Assign and Copy are added to Containers.Doubly\_Linked\_Lists. If an instance of Containers.Doubly\_Linked\_Lists is referenced in a use\_clause, and an entity E with the same defining\_identifier as a new entity in Containers.Doubly\_Linked\_Lists is defined in a package that is also referenced in a use\_clause, the entity E may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur. 164.c/3

*Extensions to Ada 2005*

{AI05-0212-1} Added iterator, reference, and indexing support to make list containers more convenient to use. 164.d/3

*Wording Changes from Ada 2005*

{AI05-0001-1} Generalized the definition of Move. Specified which elements are read/written by stream attributes. 164.e/3

{AI05-0022-1} **Correction:** Added a Bounded (Run-Time) Error to cover tampering by generic actual subprograms. 164.f/3

{AI05-0027-1} **Correction:** Added a Bounded (Run-Time) Error to cover access to finalized list containers. 164.g/3

{AI05-0044-1} **Correction:** Redefined "<" actuals to require a strict weak ordering; the old definition allowed indeterminant comparisons that would not have worked in a container. 164.h/3

{AI05-0084-1} **Correction:** Added a pragma Remote\_Types so that containers can be used in distributed programs. 164.i/3

{AI05-0160-1} **Correction:** Revised the definition of invalid cursors to cover missing (and new) cases. 164.j/3

{AI05-0257-1} **Correction:** Added missing wording to describe the Position after Inserting 0 elements. 164.k/3

{AI05-0265-1} **Correction:** Defined when a container prohibits tampering in order to more clearly define where the check is made and the exception raised. 164.l/3

## A.18.4 Maps

{AI95-00302-03} The language-defined generic packages Containers.Hashed\_Maps and Containers.Ordered\_Maps provide private types Map and Cursor, and a set of operations for each type. A map container allows an arbitrary type to be used as a key to find the element associated with that key. A hashed map uses a hash function to organize the keys, while an ordered map orders the keys per a specified relation. 1/2

{AI95-00302-03} {AI05-0299-1} This subclause describes the declarations that are common to both kinds of maps. See A.18.5 for a description of the semantics specific to Containers.Hashed\_Maps and A.18.6 for a description of the semantics specific to Containers.Ordered\_Maps. 2/3

*Static Semantics*

{AI95-00302-03} The actual function for the generic formal function "=" on Element\_Type values is expected to define a reflexive and symmetric relationship and return the same result value each time it is called with a particular pair of values. If it behaves in some other manner, the function "=" on map values returns an unspecified value. The exact arguments and number of calls of this generic formal function by the function "=" on map values are unspecified. 3/2

**Ramification:** If the actual function for "=" is not symmetric and consistent, the result returned by "=" for Map objects cannot be predicted. The implementation is not required to protect against "=" raising an exception, or returning random results, or any other "bad" behavior. And it can call "=" in whatever manner makes sense. But note that only the result of "=" for Map objects is unspecified; other subprograms are not allowed to break if "=" is bad (they aren't expected to use "="). 3.a/2

{AI95-00302-03} The type Map is used to represent maps. The type Map needs finalization (see 7.6). 4/2

- 5/2 {AI95-00302-03} A map contains pairs of keys and elements, called *nodes*. Map cursors designate nodes, but also can be thought of as designating an element (the element contained in the node) for consistency with the other containers. There exists an equivalence relation on keys, whose definition is different for hashed maps and ordered maps. A map never contains two or more nodes with equivalent keys. The *length* of a map is the number of nodes it contains.
- 6/2 {AI95-00302-03} Each nonempty map has two particular nodes called the *first node* and the *last node* (which may be the same). Each node except for the last node has a *successor node*. If there are no other intervening operations, starting with the first node and repeatedly going to the successor node will visit each node in the map exactly once until the last node is reached. The exact definition of these terms is different for hashed maps and ordered maps.
- 7/2 {AI95-00302-03} [Some operations of these generic packages have access-to-subprogram parameters. To ensure such operations are well-defined, they guard against certain actions by the designated subprogram. In particular, some operations check for “tampering with cursors” of a container because they depend on the set of elements of the container remaining constant, and others check for “tampering with elements” of a container because they depend on elements of the container not being replaced.]
- 8/2 {AI95-00302-03} A subprogram is said to *tamper with cursors* of a map object *M* if:
- 9/2
- it inserts or deletes elements of *M*, that is, it calls the Insert, Include, Clear, Delete, or Exclude procedures with *M* as a parameter; or
- 9.a/2 **To be honest:** Operations which are defined to be equivalent to a call on one of these operations also are included. Similarly, operations which call one of these as part of their definition are included.
- 10/2
- it finalizes *M*; or
- 10.1/3
- {AI05-0001-1} it calls the Assign procedure with *M* as the Target parameter; or
- 10.a/3 **Ramification:** We don't need to explicitly mention `assignment_statement`, because that finalizes the target object as part of the operation, and finalization of an object is already defined as tampering with cursors.
- 11/2
- it calls the Move procedure with *M* as a parameter; or
- 12/2
- it calls one of the operations defined to tamper with the cursors of *M*.
- 12.a/2 **Ramification:** Replace only modifies a key and element rather than rehashing, so it does not tamper with cursors.
- 13/2 {AI95-00302-03} A subprogram is said to *tamper with elements* of a map object *M* if:
- 14/2
- it tampers with cursors of *M*; or
- 15/2
- it replaces one or more elements of *M*, that is, it calls the Replace or Replace\_Element procedures with *M* as a parameter.
- 15.a/2 **Reason:** Complete replacement of an element can cause its memory to be deallocated while another operation is holding onto a reference to it. That can't be allowed. However, a simple modification of (part of) an element is not a problem, so Update\_Element does not cause a problem.
- 15.1/3 {AI05-0265-1} When tampering with cursors is *prohibited* for a particular map object *M*, Program\_Error is propagated by a call of any language-defined subprogram that is defined to tamper with the cursors of *M*, leaving *M* unmodified. Similarly, when tampering with elements is *prohibited* for a particular map object *M*, Program\_Error is propagated by a call of any language-defined subprogram that is defined to tamper with the elements of *M* [(or tamper with the cursors of *M*)], leaving *M* unmodified.
- 15.b/3 **Proof:** Tampering with elements includes tampering with cursors, so we mention it only from completeness in the second sentence.
- 16/2 {AI95-00302-03} Empty\_Map represents the empty Map object. It has a length of 0. If an object of type Map is not otherwise initialized, it is initialized to the same value as Empty\_Map.
- 17/2 {AI95-00302-03} No\_Element represents a cursor that designates no node. If an object of type Cursor is not otherwise initialized, it is initialized to the same value as No\_Element.

|                                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                  |              |
|-------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------|
| <code>{AI95-00302-03}</code>                          | The predefined "=" operator for type <code>Cursor</code> returns <code>True</code> if both cursors are <code>No_Element</code> , or designate the same element in the same container.                                                                                                                                                                                                                                                            | 18/2         |
| <code>{AI95-00302-03}</code>                          | Execution of the default implementation of the <code>Input</code> , <code>Output</code> , <code>Read</code> , or <code>Write</code> attribute of type <code>Cursor</code> raises <code>Program_Error</code> .                                                                                                                                                                                                                                    | 19/2         |
|                                                       | <b>Reason:</b> A cursor will probably be implemented in terms of one or more access values, and the effects of streaming access values is unspecified. Rather than letting the user stream junk by accident, we mandate that streaming of cursors raise <code>Program_Error</code> by default. The attributes can always be specified if there is a need to support streaming.                                                                   | 19.a/2       |
| <code>{AI05-0001-1}</code> <code>{AI05-0262-1}</code> | <code>Map'Write</code> for a <code>Map</code> object $M$ writes <code>Length(M)</code> elements of the map to the stream. It also may write additional information about the map.                                                                                                                                                                                                                                                                | 19.1/3       |
| <code>{AI05-0001-1}</code> <code>{AI05-0262-1}</code> | <code>Map'Read</code> reads the representation of a map from the stream, and assigns to <code>Item</code> a map with the same length and elements as was written by <code>Map'Write</code> .                                                                                                                                                                                                                                                     | 19.2/3       |
|                                                       | <b>Ramification:</b> Streaming more elements than the container length is wrong. For implementation implications of this rule, see the Implementation Note in A.18.2.                                                                                                                                                                                                                                                                            | 19.b/3       |

| <code>{AI95-00302-03}</code>                          | If <code>Position</code> equals <code>No_Element</code> , then <code>Constraint_Error</code> is propagated. Otherwise, <code>Element</code> returns the element component of the node designated by <code>Position</code> .                                                                                                                                                                                                                      | 34/2         |

- 35/2 **procedure** Replace\_Element (Container : **in out** Map;  
Position : **in** Cursor;  
New\_Item : **in** Element\_Type);
- 36/3 {AI95-00302-03} {AI05-0264-1} If Position equals No\_Element, then Constraint\_Error is propagated; if Position does not designate an element in Container, then Program\_Error is propagated. Otherwise, Replace\_Element assigns New\_Item to the element of the node designated by Position.
- 37/2 **procedure** Query\_Element  
(Position : **in** Cursor;  
Process : **not null access procedure** (Key : **in** Key\_Type;  
Element : **in** Element\_Type));
- 38/3 {AI95-00302-03} {AI05-0021-1} {AI05-0265-1} If Position equals No\_Element, then Constraint\_Error is propagated. Otherwise, Query\_Element calls Process.all with the key and element from the node designated by Position as the arguments. Tampering with the elements of the map that contains the element designated by Position is prohibited during the execution of the call on Process.all. Any exception raised by Process.all is propagated.
- 39/2 **procedure** Update\_Element  
(Container : **in out** Map;  
Position : **in** Cursor;  
Process : **not null access procedure** (Key : **in** Key\_Type;  
Element : **in out** Element\_Type));
- 40/3 {AI95-00302-03} {AI05-0264-1} {AI05-0265-1} If Position equals No\_Element, then Constraint\_Error is propagated; if Position does not designate an element in Container, then Program\_Error is propagated. Otherwise, Update\_Element calls Process.all with the key and element from the node designated by Position as the arguments. Tampering with the elements of Container is prohibited during the execution of the call on Process.all. Any exception raised by Process.all is propagated.
- 41/2 If Element\_Type is unconstrained and definite, then the actual Element parameter of Process.all shall be unconstrained.
- 41.a/2 **Ramification:** This means that the elements cannot be directly allocated from the heap; it must be possible to change the discriminants of the element in place.
- 41.1/3 **type** Constant\_Reference\_Type  
(Element : **not null access constant** Element\_Type) **is private**  
**with** Implicit\_Dereference => Element;
- 41.2/3 **type** Reference\_Type (Element : **not null access** Element\_Type) **is private**  
**with** Implicit\_Dereference => Element;
- 41.3/3 {AI05-0212-1} The types Constant\_Reference\_Type and Reference\_Type need finalization.
- 41.4/3 The default initialization of an object of type Constant\_Reference\_Type or Reference\_Type propagates Program\_Error.
- 41.b/3 **Reason:** It is expected that Reference\_Type (and Constant\_Reference\_Type) will be a controlled type, for which finalization will have some action to terminate the tampering check for the associated container. If the object is created by default, however, there is no associated container. Since this is useless, and supporting this case would take extra work, we define it to raise an exception.
- 41.5/3 **function** Constant\_Reference (Container : **aliased in** Map;  
Position : **in** Cursor)  
**return** Constant\_Reference\_Type;
- 41.6/3 {AI05-0212-1} {AI05-0269-1} This function (combined with the Constant\_Indexing and Implicit\_Dereference aspects) provides a convenient way to gain read access to an individual element of a map given a cursor.

- {AI05-0212-1}* *{AI05-0265-1}* If `Position` equals `No_Element`, then `Constraint_Error` is propagated; if `Position` does not designate an element in `Container`, then `Program_Error` is propagated. Otherwise, `Constant_Reference` returns an object whose discriminant is an access value that designates the element designated by `Position`. Tampering with the elements of `Container` is prohibited while the object returned by `Constant_Reference` exists and has not been finalized. 41.7/3
- ```
function Reference (Container : aliased in out Map;
                  Position  : in Cursor)
return Reference_Type;
```
- {AI05-0212-1}* *{AI05-0269-1}* This function (combined with the `Variable_Indexing` and `Implicit_Dereference` aspects) provides a convenient way to gain read and write access to an individual element of a map given a cursor. 41.9/3
- {AI05-0212-1}* *{AI05-0265-1}* If `Position` equals `No_Element`, then `Constraint_Error` is propagated; if `Position` does not designate an element in `Container`, then `Program_Error` is propagated. Otherwise, `Reference` returns an object whose discriminant is an access value that designates the element designated by `Position`. Tampering with the elements of `Container` is prohibited while the object returned by `Reference` exists and has not been finalized. 41.10/3
- ```
function Constant_Reference (Container : aliased in Map;
 Key : in Key_Type)
return Constant_Reference_Type;
```
- {AI05-0212-1}* *{AI05-0269-1}* This function (combined with the `Constant_Indexing` and `Implicit_Dereference` aspects) provides a convenient way to gain read access to an individual element of a map given a key value. 41.12/3
- Equivalent to `Constant_Reference (Container, Find (Container, Key))`. 41.13/3
- ```
function Reference (Container : aliased in out Map;
                  Key       : in Key_Type)
return Reference_Type;
```
- {AI05-0212-1}* *{AI05-0269-1}* This function (combined with the `Variable_Indexing` and `Implicit_Dereference` aspects) provides a convenient way to gain read and write access to an individual element of a map given a key value. 41.14/3
- Equivalent to `Reference (Container, Find (Container, Key))`. 41.15/3
- ```
procedure Assign (Target : in out Map; Source : in Map);
```
- {AI05-0001-1}* *{AI05-0248-1}* If `Target` denotes the same object as `Source`, the operation has no effect. Otherwise, the key/element pairs of `Source` are copied to `Target` as for an `assignment_statement` assigning `Source` to `Target`. 41.16/3
- Discussion:** *{AI05-0005-1}* This routine exists for compatibility with the bounded map containers. For an unbounded map, `Assign(A, B)` and `A := B` behave identically. For a bounded map, `:=` will raise an exception if the container capacities are different, while `Assign` will not raise an exception if there is enough room in the target. 41.c/3
- ```
procedure Move (Target : in out Map;
              Source  : in out Map);
```
- {AI95-00302-03}* *{AI05-0001-1}* *{AI05-0248-1}* *{AI05-0262-1}* If `Target` denotes the same object as `Source`, then the operation has no effect. Otherwise, the operation is equivalent to `Assign (Target, Source)` followed by `Clear (Source)`. 43/3

```

44/2  procedure Insert (Container : in out Map;
                    Key       : in     Key_Type;
                    New_Item  : in     Element_Type;
                    Position  : out Cursor;
                    Inserted  : out Boolean);

```

45/2 {AI95-00302-03} Insert checks if a node with a key equivalent to Key is already present in Container. If a match is found, Inserted is set to False and Position designates the element with the matching key. Otherwise, Insert allocates a new node, initializes it to Key and New_Item, and adds it to Container; Inserted is set to True and Position designates the newly-inserted node. Any exception raised during allocation is propagated and Container is not modified.

```

46/2  procedure Insert (Container : in out Map;
                    Key       : in     Key_Type;
                    Position  : out Cursor;
                    Inserted  : out Boolean);

```

47/2 {AI95-00302-03} Insert inserts Key into Container as per the five-parameter Insert, with the difference that an element initialized by default (see 3.3.1) is inserted.

```

48/2  procedure Insert (Container : in out Map;
                    Key       : in     Key_Type;
                    New_Item  : in     Element_Type);

```

49/2 {AI95-00302-03} Insert inserts Key and New_Item into Container as per the five-parameter Insert, with the difference that if a node with a key equivalent to Key is already in the map, then Constraint_Error is propagated.

49.a/2 **Ramification:** This is equivalent to:

```

49.b/2  declare
        Inserted : Boolean; C : Cursor;
begin
    Insert (Container, Key, New_Item, C, Inserted);
    if not Inserted then
        raise Constraint_Error;
    end if;
end;

```

49.c/2 but doesn't require the hassle of **out** parameters.

```

50/2  procedure Include (Container : in out Map;
                    Key       : in     Key_Type;
                    New_Item  : in     Element_Type);

```

51/2 {AI95-00302-03} Include inserts Key and New_Item into Container as per the five-parameter Insert, with the difference that if a node with a key equivalent to Key is already in the map, then this operation assigns Key and New_Item to the matching node. Any exception raised during assignment is propagated.

51.a/2 **Ramification:** This is equivalent to:

```

51.b/2  declare
        C : Cursor := Find (Container, Key);
begin
    if C = No_Element then
        Insert (Container, Key, New_Item);
    else
        Replace (Container, Key, New_Item);
    end if;
end;

```

51.c/2 but this avoids doing the search twice.

procedure Replace (Container : in out Map; Key : in Key_Type; New_Item : in Element_Type);	52/2
{AI95-00302-03} Replace checks if a node with a key equivalent to Key is present in Container. If a match is found, Replace assigns Key and New_Item to the matching node; otherwise, Constraint_Error is propagated.	53/2
Discussion: We update the key as well as the element, as the key might include additional information that does not participate in equivalence. If only the element needs to be updated, use Replace_Element (Find (Container, Key), New_Element).	53.a/2
procedure Exclude (Container : in out Map; Key : in Key_Type);	54/2
{AI95-00302-03} Exclude checks if a node with a key equivalent to Key is present in Container. If a match is found, Exclude removes the node from the map.	55/2
Ramification: Exclude should work on an empty map; nothing happens in that case.	55.a/2
procedure Delete (Container : in out Map; Key : in Key_Type);	56/2
{AI95-00302-03} Delete checks if a node with a key equivalent to Key is present in Container. If a match is found, Delete removes the node from the map; otherwise, Constraint_Error is propagated.	57/2
procedure Delete (Container : in out Map; Position : in out Cursor);	58/2
{AI95-00302-03} If Position equals No_Element, then Constraint_Error is propagated. If Position does not designate an element in Container, then Program_Error is propagated. Otherwise, Delete removes the node designated by Position from the map. Position is set to No_Element on return.	59/2
Ramification: The check on Position checks that the cursor does not belong to some other map. This check implies that a reference to the map is included in the cursor value. This wording is not meant to require detection of dangling cursors; such cursors are defined to be invalid, which means that execution is erroneous, and any result is allowed (including not raising an exception).	59.a/2
function First (Container : Map) return Cursor;	60/2
{AI95-00302-03} If Length (Container) = 0, then First returns No_Element. Otherwise, First returns a cursor that designates the first node in Container.	61/2
function Next (Position : Cursor) return Cursor;	62/2
{AI95-00302-03} Returns a cursor that designates the successor of the node designated by Position. If Position designates the last node, then No_Element is returned. If Position equals No_Element, then No_Element is returned.	63/2
procedure Next (Position : in out Cursor);	64/2
{AI95-00302-03} Equivalent to Position := Next (Position).	65/2
function Find (Container : Map; Key : Key_Type) return Cursor;	66/2
{AI95-00302-03} If Length (Container) equals 0, then Find returns No_Element. Otherwise, Find checks if a node with a key equivalent to Key is present in Container. If a match is found, a cursor designating the matching node is returned; otherwise, No_Element is returned.	67/2
function Element (Container : Map; Key : Key_Type) return Element_Type;	68/2
{AI95-00302-03} Equivalent to Element (Find (Container, Key)).	69/2

70/2 **function** Contains (Container : Map;
 Key : Key_Type) **return** Boolean;
 71/2 {AI95-00302-03} Equivalent to Find (Container, Key) /= No_Element.

Paragraphs 72 and 73 were moved above.

74/2 **procedure** Iterate
 (Container : **in** Map;
 Process : **not null access procedure** (Position : **in** Cursor));

75/3 {AI95-00302-03} {AI05-0265-1} Iterate calls Process.all with a cursor that designates each node in Container, starting with the first node and moving the cursor according to the successor relation. Tampering with the cursors of Container is prohibited during the execution of a call on Process.all. Any exception raised by Process.all is propagated.

75.a/2 **Implementation Note:** The “tamper with cursors” check takes place when the operations that insert or delete elements, and so on, are called.

75.b/2 See Iterate for vectors (A.18.2) for a suggested implementation of the check.

Bounded (Run-Time) Errors

75.1/3 {AI05-0022-1} {AI05-0248-1} It is a bounded error for the actual function associated with a generic formal subprogram, when called as part of an operation of a map package, to tamper with elements of any map parameter of the operation. Either Program_Error is raised, or the operation works as defined on the value of the map either prior to, or subsequent to, some or all of the modifications to the map.

75.2/3 {AI05-0027-1} It is a bounded error to call any subprogram declared in the visible part of a map package when the associated container has been finalized. If the operation takes Container as an **in out** parameter, then it raises Constraint_Error or Program_Error. Otherwise, the operation either proceeds as it would for an empty container, or it raises Constraint_Error or Program_Error.

Erroneous Execution

76/2 {AI95-00302-03} A Cursor value is *invalid* if any of the following have occurred since it was created:

- 77/2 • The map that contains the node it designates has been finalized;
- 77.1/3 • {AI05-0160-1} The map that contains the node it designates has been used as the Target of a call to Assign, or as the target of an assignment_statement;
- 78/2 • The map that contains the node it designates has been used as the Source or Target of a call to Move; or
- 79/3 • {AI05-0160-1} {AI05-0262-1} The node it designates has been removed from the map that previously contained the node.

79.a/3 **Ramification:** {AI05-0160-1} This can happen directly via calls to Clear, Exclude, and Delete.

80/2 The result of "=" or Has_Element is unspecified if these functions are called with an invalid cursor parameter. Execution is erroneous if any other subprogram declared in Containers.Hashing_Maps or Containers.Ordered_Maps is called with an invalid cursor parameter.

80.a/2 **Discussion:** The list above is intended to be exhaustive. In other cases, a cursor value continues to designate its original element. For instance, cursor values survive the insertion and deletion of other nodes.

80.b/2 While it is possible to check for these cases, in many cases the overhead necessary to make the check is substantial in time or space. Implementations are encouraged to check for as many of these cases as possible and raise Program_Error if detected.

80.1/3 {AI05-0212-1} Execution is erroneous if the map associated with the result of a call to Reference or Constant_Reference is finalized before the result object returned by the call to Reference or Constant_Reference is finalized.

- Reason:** Each object of `Reference_Type` and `Constant_Reference_Type` probably contains some reference to the originating container. If that container is prematurely finalized (which is only possible via `Unchecked_Deallocation`, as accessibility checks prevent passing a container to `Reference` that will not live as long as the result), the finalization of the object of `Reference_Type` will try to access a nonexistent object. This is a normal case of a dangling pointer created by `Unchecked_Deallocation`; we have to explicitly mention it here as the pointer in question is not visible in the specification of the type. (This is the same reason we have to say this for invalid cursors.) 80.c/3
- Implementation Requirements*
- {AI95-00302-03} No storage associated with a `Map` object shall be lost upon assignment or scope exit. 81/2
- {AI95-00302-03} {AI05-0262-1} The execution of an `assignment_statement` for a map shall have the effect of copying the elements from the source map object to the target map object and changing the length of the target object to that of the source object. 82/3
- Implementation Note:** {AI05-0298-1} An assignment of a `Map` is a “deep” copy; that is the elements are copied as well as the data structures. We say “effect of” in order to allow the implementation to avoid copying elements immediately if it wishes. For instance, an implementation that avoided copying until one of the containers is modified would be allowed. (Note that this implementation would require care, see A.18.2 for more.) 82.a/3
- Implementation Advice*
- {AI95-00302-03} `Move` should not copy elements, and should minimize copying of internal data structures. 83/2
- Implementation Advice:** `Move` for a map should not copy elements, and should minimize copying of internal data structures. 83.a/2
- Implementation Note:** Usually that can be accomplished simply by moving the pointer(s) to the internal data structures from the Source container to the Target container. 83.b/2
- {AI95-00302-03} If an exception is propagated from a map operation, no storage should be lost, nor any elements removed from a map unless specified by the operation. 84/2
- Implementation Advice:** If an exception is propagated from a map operation, no storage should be lost, nor any elements removed from a map unless specified by the operation. 84.a/2
- Reason:** This is important so that programs can recover from errors. But we don't want to require heroic efforts, so we just require documentation of cases where this can't be accomplished. 84.b/2
- Wording Changes from Ada 95*
- {AI95-00302-03} This description of maps is new; the extensions are documented with the specific packages. 84.c/2
- Extensions to Ada 2005*
- {AI05-0212-1} Added reference support to make map containers more convenient to use. 84.d/3
- Wording Changes from Ada 2005*
- {AI05-0001-1} Added procedure `Assign`; the extension and incompatibility is documented with the specific packages. 84.e/3
- {AI05-0001-1} Generalized the definition of `Move`. Specified which elements are read/written by stream attributes. 84.f/3
- {AI05-0022-1} **Correction:** Added a Bounded (Run-Time) Error to cover tampering by generic actual subprograms. 84.g/3
- {AI05-0027-1} **Correction:** Added a Bounded (Run-Time) Error to cover access to finalized map containers. 84.h/3
- {AI05-0160-1} **Correction:** Revised the definition of invalid cursors to cover missing (and new) cases. 84.i/3
- {AI05-0265-1} **Correction:** Defined when a container prohibits tampering in order to more clearly define where the check is made and the exception raised. 84.j/3

A.18.5 The Generic Package Containers.Hashing_Maps

Static Semantics

```

1/2 {AI95-00302-03} The generic library package Containers.Hashing_Maps has the following declaration:
2/3   {AI05-0084-1} {AI05-0212-1} with Ada.Iterator_Interfaces;
   generic
     type Key_Type is private;
     type Element_Type is private;
     with function Hash (Key : Key_Type) return Hash_Type;
     with function Equivalent_Keys (Left, Right : Key_Type)
       return Boolean;
     with function "=" (Left, Right : Element_Type)
       return Boolean is <>;
   package Ada.Containers.Hashing_Maps is
     pragma Preelaborate (Hashing_Maps);
     pragma Remote_Types (Hashing_Maps);
3/3   {AI05-0212-1}   type Map is tagged private
     with Constant_Indexing => Constant_Reference,
       Variable_Indexing => Reference,
       Default_Iterator => Iterate,
       Iterator_Element => Element_Type;
     pragma Preelaborable_Initialization (Map);
4/2   type Cursor is private;
     pragma Preelaborable_Initialization (Cursor);
5/2   Empty_Map : constant Map;
6/2   No_Element : constant Cursor;
6.1/3 {AI05-0212-1}   function Has_Element (Position : Cursor) return Boolean;
6.2/3 {AI05-0212-1}   package Map_Iterator_Interfaces is new
     Ada.Iterator_Interfaces (Cursor, Has_Element);
7/2   function "=" (Left, Right : Map) return Boolean;
8/2   function Capacity (Container : Map) return Count_Type;
9/2   procedure Reserve_Capacity (Container : in out Map;
     Capacity : in Count_Type);
10/2  function Length (Container : Map) return Count_Type;
11/2  function Is_Empty (Container : Map) return Boolean;
12/2  procedure Clear (Container : in out Map);
13/2  function Key (Position : Cursor) return Key_Type;
14/2  function Element (Position : Cursor) return Element_Type;
15/2  procedure Replace_Element (Container : in out Map;

```

{AI95-00302-03} An object of type Map contains an expandable hash table, which is used to provide direct access to nodes. The *capacity* of an object of type Map is the maximum number of nodes that can be inserted into the hash table prior to it being automatically expanded.

41.a/2 **Implementation Note:** The expected implementation for a Map uses a hash table which is grown when it is too small, with linked lists hanging off of each bucket. Note that in that implementation a cursor needs a back pointer to the Map object to implement iteration; that could either be in the nodes, or in the cursor object. To provide an average $O(1)$ access time, capacity would typically equal the number of buckets in such an implementation, so that the average bucket linked list length would be no more than 1.0.

41.b/2 There is no defined relationship between elements in a hashed map. Typically, iteration will return elements in the order that they are hashed in.

42/2 {AI95-00302-03} Two keys $K1$ and $K2$ are defined to be *equivalent* if `Equivalent_Keys (K1, K2)` returns True.

43/2 {AI95-00302-03} The actual function for the generic formal function Hash is expected to return the same value each time it is called with a particular key value. For any two equivalent key values, the actual for Hash is expected to return the same value. If the actual for Hash behaves in some other manner, the behavior of this package is unspecified. Which subprograms of this package call Hash, and how many times they call it, is unspecified.

43.a/2 **Implementation Note:** The implementation is not required to protect against Hash raising an exception, or returning random numbers, or any other “bad” behavior. It's not practical to do so, and a broken Hash function makes the container unusable.

43.b/2 The implementation can call Hash whenever it is needed; we don't want to specify how often that happens. The result must remain the same (this is logically a pure function), or the behavior is unspecified.

44/2 {AI95-00302-03} The actual function for the generic formal function Equivalent_Keys on Key_Type values is expected to return the same value each time it is called with a particular pair of key values. It should define an equivalence relationship, that is, be reflexive, symmetric, and transitive. If the actual for Equivalent_Keys behaves in some other manner, the behavior of this package is unspecified. Which subprograms of this package call Equivalent_Keys, and how many times they call it, is unspecified.

44.a/2 **Implementation Note:** As with Hash, the implementation is not required to protect against Equivalent_Keys raising an exception or returning random results. Similarly, the implementation can call this operation whenever it is needed. The result must remain the same (this is a logically pure function), or the behavior is unspecified.

45/2 {AI95-00302-03} If the value of a key stored in a node of a map is changed other than by an operation in this package such that at least one of Hash or Equivalent_Keys give different results, the behavior of this package is unspecified.

- Implementation Note:** The implementation is not required to protect against changes to key values other than via the operations declared in the `Hashed_Maps` package. 45.a/2
- To see how this could happen, imagine an instance of `Hashed_Maps` where the key type is an access-to-variable type and `Hash` returns a value derived from the components of the designated object. Then, any operation that has a key value could modify those components and change the hash value. 45.b/2
- ```
Key (Map).Some_Component := New_Value;
```
- This is really a design error on the part of the user of the map; it shouldn't be possible to modify keys stored in a map. But we can't prevent this error anymore than we can prevent someone passing as `Hash` a random number generator. 45.d/2
- {AI95-00302-03}* Which nodes are the first node and the last node of a map, and which node is the successor of a given node, are unspecified, other than the general semantics described in A.18.4. 46/2
- Implementation Note:** Typically the first node will be the first node in the first bucket, the last node will be the last node in the last bucket, and the successor will be obtained by following the collision list, and going to the next bucket at the end of each bucket. 46.a/2
- ```
function Capacity (Container : Map) return Count_Type;
```
- {AI95-00302-03}* Returns the capacity of `Container`. 47/2 48/2
- ```
procedure Reserve_Capacity (Container : in out Map;
 Capacity : in Count_Type);
```
- {AI95-00302-03}* `Reserve_Capacity` allocates a new hash table such that the length of the resulting map can become at least the value `Capacity` without requiring an additional call to `Reserve_Capacity`, and is large enough to hold the current length of `Container`. `Reserve_Capacity` then rehashes the nodes in `Container` onto the new hash table. It replaces the old hash table with the new hash table, and then deallocates the old hash table. Any exception raised during allocation is propagated and `Container` is not modified. 50/2
- `Reserve_Capacity` tampers with the cursors of `Container`. 51/2
- Implementation Note:** This routine is used to preallocate the internal hash table to the specified capacity such that future `Inserts` do not require expansion of the hash table. Therefore, the implementation should allocate the needed memory to make that true at this point, even though the visible semantics could be preserved by waiting until enough elements are inserted. 51.a/2
- {AI05-0005-1}* While `Reserve_Capacity` can be used to reduce the capacity of a map, we do not specify whether an implementation actually supports reduction of the capacity. Since the actual capacity can be anything greater than or equal to `Capacity`, an implementation never has to reduce the capacity. 51.b/3
- `Reserve_Capacity` tampers with the cursors, as rehashing probably will change the order that elements are stored in the map. 51.c/2
- ```
procedure Clear (Container : in out Map);
```
- {AI95-00302-03}* In addition to the semantics described in A.18.4, `Clear` does not affect the capacity of `Container`. 52/2 53/2
- ```
procedure Assign (Target : in out Map; Source : in Map);
```
- {AI05-0001-1}* *{AI05-0248-1}* In addition to the semantics described in A.18.4, if the length of `Source` is greater than the capacity of `Target`, `Reserve_Capacity (Target, Length (Source))` is called before assigning any elements. 53.1/3 53.2/3
- ```
function Copy (Source : Map; Capacity : Count_Type := 0) return Map;
```
- {AI05-0001-1}* Returns a map whose keys and elements are initialized from the keys and elements of `Source`. If `Capacity` is 0, then the map capacity is the length of `Source`; if `Capacity` is equal to or greater than the length of `Source`, the map capacity is at least the specified value. Otherwise, the operation propagates `Capacity_Error`. 53.3/3 53.4/3

- 53.a/2 **Implementation Note:** In:
- 53.b/2

```
procedure Move (Target : in out Map;
                Source : in out Map);
```
- 53.c/2 The intended implementation is that the internal hash table of Target is first deallocated; then the internal hash table is removed from Source and moved to Target.
- 54/2

```
procedure Insert (Container : in out Map;
                 Key       : in   Key_Type;
                 New_Item  : in   Element_Type;
                 Position  : out  Cursor;
                 Inserted  : out  Boolean);
```
- 55/2 *{AI95-00302-03}* In addition to the semantics described in A.18.4, if Length (Container) equals Capacity (Container), then Insert first calls Reserve_Capacity to increase the capacity of Container to some larger value.
- 55.a/2 **Implementation Note:** Insert should only compare keys that hash to the same bucket in the hash table.
- 55.b/2 We specify when Reserve_Capacity is called to bound the overhead of capacity expansion operations (which are potentially expensive). Moreover, expansion can be predicted by comparing Capacity(Map) to Length(Map). Since we don't specify by how much the hash table is expanded, this only can be used to predict the next expansion, not later ones.
- 55.c/2 **Implementation Note:** In:
- 55.d/2

```
procedure Exclude (Container : in out Map;
                  Key       : in   Key_Type);
```
- 55.e/2 Exclude should only compare keys that hash to the same bucket in the hash table.
- 55.f/2 **Implementation Note:** In:
- 55.g/2

```
procedure Delete (Container : in out Map;
                 Key       : in   Key_Type);
```
- 55.h/2 Delete should only compare keys that hash to the same bucket in the hash table. The node containing the element may be deallocated now, or it may be saved and reused later.
- 55.i/2 **Implementation Note:** In:
- 55.j/2

```
function First (Container : Map) return Cursor;
```
- 55.k/2 In a typical implementation, this will be the first node in the lowest numbered hash bucket that contains a node.
- 55.l/2 **Implementation Note:** In:
- 55.m/2

```
function Next (Position : Cursor) return Cursor;
```
- 55.n/2 In a typical implementation, this will return the next node in a bucket; if Position is the last node in a bucket, this will return the first node in the next nonempty bucket.
- 55.o/2 A typical implementation will need to keep a pointer at the map container in the cursor in order to implement this function.
- 55.p/2 **Implementation Note:** In:
- 55.q/2

```
function Find (Container : Map;
              Key       : Key_Type) return Cursor;
```
- 55.r/2 Find should only compare keys that hash to the same bucket in the hash table.
- 56/2

```
function Equivalent_Keys (Left, Right : Cursor)
return Boolean;
```
- 57/2 *{AI95-00302-03}* Equivalent to Equivalent_Keys (Key (Left), Key (Right)).
- 58/2

```
function Equivalent_Keys (Left : Cursor;
                         Right : Key_Type) return Boolean;
```
- 59/2 *{AI95-00302-03}* Equivalent to Equivalent_Keys (Key (Left), Right).
- 60/2

```
function Equivalent_Keys (Left : Key_Type;
                         Right : Cursor) return Boolean;
```
- 61/2 *{AI95-00302-03}* Equivalent to Equivalent_Keys (Left, Key (Right)).

function Iterate (Container : **in** Map) 61.1/3
return Map_Iterator_Interfaces.Forward_Iterator'Class;

{AI05-0212-1} {AI05-0265-1} {AI05-0269-1} Iterate returns an iterator object (see 5.5.1) that will generate a value for a loop parameter (see 5.5.2) designating each node in Container, starting with the first node and moving the cursor according to the successor relation. Tampering with the cursors of Container is prohibited while the iterator object exists (in particular, in the sequence_of_statements of the loop_statement whose iterator_specification denotes this object). The iterator object needs finalization. 61.2/3

Implementation Advice

{AI95-00302-03} If N is the length of a map, the average time complexity of the subprograms Element, Insert, Include, Replace, Delete, Exclude and Find that take a key parameter should be $O(\log N)$. The average time complexity of the subprograms that take a cursor parameter should be $O(1)$. The average time complexity of Reserve_Capacity should be $O(N)$. 62/2

Implementation Advice: The average time complexity of Element, Insert, Include, Replace, Delete, Exclude and Find operations that take a key parameter for Containers.Hashing_Maps should be $O(\log N)$. The average time complexity of the subprograms of Containers.Hashing_Maps that take a cursor parameter should be $O(1)$. The average time complexity of Containers.Hashing_Maps.Reserve_Capacity should be $O(N)$. 62.a/2

Reason: We do not mean to overly constrain implementation strategies here. However, it is important for portability that the performance of large containers has roughly the same factors on different implementations. If a program is moved to an implementation for which Find is $O(N)$, that program could be unusable when the maps are large. We allow $O(\log N)$ access because the proportionality constant and caching effects are likely to be larger than the log factor, and we don't want to discourage innovative implementations. 62.b/2

Extensions to Ada 95

{AI95-00302-03} The generic package Containers.Hashing_Maps is new. 62.c/2

Incompatibilities With Ada 2005

{AI05-0001-1} Subprograms Assign and Copy are added to Containers.Hashing_Maps. If an instance of Containers.Hashing_Maps is referenced in a use_clause, and an entity E with the same defining_identifier as a new entity in Containers.Hashing_Maps is defined in a package that is also referenced in a use_clause, the entity E may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur. 62.d/3

Extensions to Ada 2005

{AI05-0212-1} Added iterator and indexing support to make hashed map containers more convenient to use. 62.e/3

Wording Changes from Ada 2005

{AI05-0084-1} **Correction:** Added a pragma Remote_Types so that containers can be used in distributed programs. 62.f/3

A.18.6 The Generic Package Containers.Ordered_Maps

Static Semantics

{AI95-00302-03} The generic library package Containers.Ordered_Maps has the following declaration: 1/2

```
{AI05-0084-1} {AI05-0212-1} with Ada.Iterator_Interfaces; 2/3
generic
  type Key_Type is private;
  type Element_Type is private;
  with function "<" (Left, Right : Key_Type) return Boolean is <>;
  with function "=" (Left, Right : Element_Type) return Boolean is <>;
package Ada.Containers.Ordered_Maps is
  pragma Preelaborate(Ordered_Maps);
  pragma Remote_Types(Ordered_Maps);
  function Equivalent_Keys (Left, Right : Key_Type) return Boolean; 3/2
```

```

4/3      {AI05-0212-1}    type Map is tagged private
          with Constant_Indexing => Constant_Reference,
              Variable_Indexing => Reference,
              Default_Iterator  => Iterate,
              Iterator_Element  => Element_Type;
          pragma Preelaborable_Initialization(Map);
5/2      type Cursor is private;
          pragma Preelaborable_Initialization(Cursor);

          return Map_Iterator_Interfaces.Reversible_Iterator'Class;
52/2     private
53/2     ... -- not specified by the language
54/2     end Ada.Containers.Ordered_Maps;

```

55/2 {AI95-00302-03} Two keys $K1$ and $K2$ are *equivalent* if both $K1 < K2$ and $K2 < K1$ return False, using the generic formal " $<$ " operator for keys. Function `Equivalent_Keys` returns True if Left and Right are equivalent, and False otherwise.

56/3 {AI95-00302-03} {AI05-0044-1} The actual function for the generic formal function " $<$ " on `Key_Type` values is expected to return the same value each time it is called with a particular pair of key values. It should define a strict weak ordering relationship (see A.18). If the actual for " $<$ " behaves in some other manner, the behavior of this package is unspecified. Which subprograms of this package call " $<$ " and how many times they call it, is unspecified.

56.a/2 **Implementation Note:** The implementation is not required to protect against " $<$ " raising an exception, or returning random results, or any other "bad" behavior. It's not practical to do so, and a broken " $<$ " function makes the container unusable.

56.b/2 The implementation can call " $<$ " whenever it is needed; we don't want to specify how often that happens. The result must remain the same (this is a logically pure function), or the behavior is unspecified.

57/2 {AI95-00302-03} If the value of a key stored in a map is changed other than by an operation in this package such that at least one of " $<$ " or " $=$ " give different results, the behavior of this package is unspecified.

57.a/2 **Implementation Note:** The implementation is not required to protect against changes to key values other than via the operations declared in the `Ordered_Maps` package.

57.b/2 To see how this could happen, imagine an instance of `Ordered_Maps` package where the key type is an access-to-variable type and " $<$ " returns a value derived from comparing the components of the designated objects. Then, any operation that has a key value (even if the key value is constant) could modify those components and change the result of " $<$ ".

57.c/2 `Key (Map).Some_Component := New_Value;`

57.d/2 This is really a design error on the part of the user of the map; it shouldn't be possible to modify keys stored in a map such that " $<$ " changes. But we can't prevent this error anymore than we can prevent someone passing as " $<$ " a routine that produces random answers.

58/3 {AI95-00302-03} {AI05-0262-1} The *first node* of a nonempty map is the one whose key is less than the key of all the other nodes in the map. The *last node* of a nonempty map is the one whose key is greater than the key of all the other elements in the map. The *successor* of a node is the node with the smallest key that is larger than the key of the given node. The *predecessor* of a node is the node with the largest key that is smaller than the key of the given node. All comparisons are done using the generic formal " $<$ " operator for keys.

58.1/3 `function Copy (Source : Map) return Map;`

58.2/3 {AI05-0001-1} Returns a map whose keys and elements are initialized from the corresponding keys and elements of `Source`.

procedure Delete_First (Container : in out Map);	59/2
{AI95-00302-03} {AI05-0264-1} If Container is empty, Delete_First has no effect. Otherwise, the node designated by First (Container) is removed from Container. Delete_First tampers with the cursors of Container.	60/3
procedure Delete_Last (Container : in out Map);	61/2
{AI95-00302-03} {AI05-0264-1} If Container is empty, Delete_Last has no effect. Otherwise, the node designated by Last (Container) is removed from Container. Delete_Last tampers with the cursors of Container.	62/3
function First_Element (Container : Map) return Element_Type;	63/2
{AI95-00302-03} Equivalent to Element (First (Container)).	64/2
function First_Key (Container : Map) return Key_Type;	65/2
{AI95-00302-03} Equivalent to Key (First (Container)).	66/2
function Last (Container : Map) return Cursor;	67/2
{AI95-00302-03} Returns a cursor that designates the last node in Container. If Container is empty, returns No_Element.	68/2
function Last_Element (Container : Map) return Element_Type;	69/2
{AI95-00302-03} Equivalent to Element (Last (Container)).	70/2
function Last_Key (Container : Map) return Key_Type;	71/2
{AI95-00302-03} Equivalent to Key (Last (Container)).	72/2
function Previous (Position : Cursor) return Cursor;	73/2
{AI95-00302-03} {AI05-0262-1} If Position equals No_Element, then Previous returns No_Element. Otherwise, Previous returns a cursor designating the predecessor node of the one designated by Position. If Position designates the first element, then Previous returns No_Element.	74/3
procedure Previous (Position : in out Cursor);	75/2
{AI95-00302-03} Equivalent to Position := Previous (Position).	76/2
function Floor (Container : Map; Key : Key_Type) return Cursor;	77/2
{AI95-00302-03} {AI05-0264-1} Floor searches for the last node whose key is not greater than Key, using the generic formal "<" operator for keys. If such a node is found, a cursor that designates it is returned. Otherwise, No_Element is returned.	78/3
function Ceiling (Container : Map; Key : Key_Type) return Cursor;	79/2
{AI95-00302-03} {AI05-0264-1} Ceiling searches for the first node whose key is not less than Key, using the generic formal "<" operator for keys. If such a node is found, a cursor that designates it is returned. Otherwise, No_Element is returned.	80/3
function "<" (Left, Right : Cursor) return Boolean;	81/2
{AI95-00302-03} Equivalent to Key (Left) < Key (Right).	82/2
function ">" (Left, Right : Cursor) return Boolean;	83/2
{AI95-00302-03} Equivalent to Key (Right) < Key (Left).	84/2

- 85/2 **function** "<" (Left : Cursor; Right : Key_Type) **return** Boolean;
86/2 {AI95-00302-03} Equivalent to Key (Left) < Right.
- 87/2 **function** ">" (Left : Cursor; Right : Key_Type) **return** Boolean;
88/2 {AI95-00302-03} Equivalent to Right < Key (Left).
- 89/2 **function** "<" (Left : Key_Type; Right : Cursor) **return** Boolean;
90/2 {AI95-00302-03} Equivalent to Left < Key (Right).
- 91/2 **function** ">" (Left : Key_Type; Right : Cursor) **return** Boolean;
92/2 {AI95-00302-03} Equivalent to Key (Right) < Left.
- 93/2 **procedure** Reverse_Iterate
 (Container : **in** Map;
 Process : **not null access procedure** (Position : **in** Cursor));
- 94/3 {AI95-00302-03} {AI05-0212-1} Iterates over the nodes in Container as per procedure Iterate,
 with the difference that the nodes are traversed in predecessor order, starting with the last node.
- 94.1/3 **function** Iterate (Container : **in** Map)
 return Map_Iterator_Interfaces.Reversible_Iterator'Class;
- 94.2/3 {AI05-0212-1} {AI05-0265-1} {AI05-0269-1} Iterate returns a reversible iterator object (see
5.5.1) that will generate a value for a loop parameter (see 5.5.2) designating each node in
Container, starting with the first node and moving the cursor according to the successor relation
when used as a forward iterator, and starting with the last node and moving the cursor according
to the predecessor relation when used as a reverse iterator. Tampering with the cursors of
Container is prohibited while the iterator object exists (in particular, in the
sequence_of_statements of the loop_statement whose iterator_specification denotes this
object). The iterator object needs finalization.
- 94.3/3 **function** Iterate (Container : **in** Map; Start : **in** Cursor)
 return Map_Iterator_Interfaces.Reversible_Iterator'Class;
- 94.4/3 {AI05-0262-1} {AI05-0265-1} {AI05-0269-1} If Start is not No_Element and does not designate
an item in Container, then Program_Error is propagated. If Start is No_Element, then
Constraint_Error is propagated. Otherwise, Iterate returns a reversible iterator object (see 5.5.1)
that will generate a value for a loop parameter (see 5.5.2) designating each node in Container,
starting with the node designated by Start and moving the cursor according to the successor
relation when used as a forward iterator, or moving the cursor according to the predecessor
relation when used as a reverse iterator. Tampering with the cursors of Container is prohibited
while the iterator object exists (in particular, in the sequence_of_statements of the
loop_statement whose iterator_specification denotes this object). The iterator object needs
finalization.
- 94.a/3 **Discussion:** Exits are allowed from the loops created using the iterator objects. In particular, to stop the iteration at a
particular cursor, just add
- 94.b/3 **exit when** Cur = Stop;
- 94.c/3 in the body of the loop (assuming that Cur is the loop parameter and Stop is the cursor that you want to stop at).

Implementation Advice

- 95/2 {AI95-00302-03} If N is the length of a map, then the worst-case time complexity of the Element, Insert,
Include, Replace, Delete, Exclude and Find operations that take a key parameter should be $O((\log N)**2)$
or better. The worst-case time complexity of the subprograms that take a cursor parameter should be $O(1)$.

Implementation Advice: The worst-case time complexity of Element, Insert, Include, Replace, Delete, Exclude and Find operations that take a key parameter for Containers.Ordered_Maps should be $O((\log N)^*2)$ or better. The worst-case time complexity of the subprograms of Containers.Ordered_Maps that take a cursor parameter should be $O(1)$. 95.a/2

Implementation Note: A balanced (red-black) tree for keys has $O(\log N)$ worst-case performance. Note that a $O(N)$ worst-case implementation (like a list) would be wrong. 95.b/2

Reason: We do not mean to overly constrain implementation strategies here. However, it is important for portability that the performance of large containers has roughly the same factors on different implementations. If a program is moved to an implementation that takes $O(N)$ to find elements, that program could be unusable when the maps are large. We allow the extra $\log N$ factors because the proportionality constant and caching effects are likely to be larger than the log factor, and we don't want to discourage innovative implementations. 95.c/2

Extensions to Ada 95

{AI95-00302-03} The generic package Containers.Ordered_Maps is new. 95.d/2

Incompatibilities With Ada 2005

{AI05-0001-1} Subprograms Assign and Copy are added to Containers.Ordered_Maps. If an instance of Containers.Ordered_Maps is referenced in a use_clause, and an entity E with the same defining_identifier as a new entity in Containers.Ordered_Maps is defined in a package that is also referenced in a use_clause, the entity E may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur. 95.e/3

Extensions to Ada 2005

{AI05-0212-1} Added iterator and indexing support to make ordered map containers more convenient to use. 95.f/3

Wording Changes from Ada 2005

{AI05-0044-1} **Correction:** Redefined "<" actuals to require a strict weak ordering; the old definition allowed indeterminant comparisons that would not have worked in a container. 95.g/3

{AI05-0084-1} **Correction:** Added a pragma Remote_Types so that containers can be used in distributed programs. 95.h/3

A.18.7 Sets

{AI95-00302-03} The language-defined generic packages Containers.Hashed_Sets and Containers.Ordered_Sets provide private types Set and Cursor, and a set of operations for each type. A set container allows elements of an arbitrary type to be stored without duplication. A hashed set uses a hash function to organize elements, while an ordered set orders its element per a specified relation. 1/2

{AI95-00302-03} {AI05-0299-1} This subclause describes the declarations that are common to both kinds of sets. See A.18.8 for a description of the semantics specific to Containers.Hashed_Sets and A.18.9 for a description of the semantics specific to Containers.Ordered_Sets. 2/3

Static Semantics

{AI95-00302-03} The actual function for the generic formal function "=" on Element_Type values is expected to define a reflexive and symmetric relationship and return the same result value each time it is called with a particular pair of values. If it behaves in some other manner, the function "=" on set values returns an unspecified value. The exact arguments and number of calls of this generic formal function by the function "=" on set values are unspecified. 3/2

Ramification: If the actual function for "=" is not symmetric and consistent, the result returned by the "=" for Set objects cannot be predicted. The implementation is not required to protect against "=" raising an exception, or returning random results, or any other "bad" behavior. And it can call "=" in whatever manner makes sense. But note that only the result of "=" for Set objects is unspecified; other subprograms are not allowed to break if "=" is bad (they aren't expected to use "="). 3.a/2

{AI95-00302-03} The type Set is used to represent sets. The type Set needs finalization (see 7.6). 4/2

- 5/2 {AI95-00302-03} A set contains elements. Set cursors designate elements. There exists an equivalence relation on elements, whose definition is different for hashed sets and ordered sets. A set never contains two or more equivalent elements. The *length* of a set is the number of elements it contains.
- 6/2 {AI95-00302-03} Each nonempty set has two particular elements called the *first element* and the *last element* (which may be the same). Each element except for the last element has a *successor element*. If there are no other intervening operations, starting with the first element and repeatedly going to the successor element will visit each element in the set exactly once until the last element is reached. The exact definition of these terms is different for hashed sets and ordered sets.
- 7/2 {AI95-00302-03} [Some operations of these generic packages have access-to-subprogram parameters. To ensure such operations are well-defined, they guard against certain actions by the designated subprogram. In particular, some operations check for “tampering with cursors” of a container because they depend on the set of elements of the container remaining constant, and others check for “tampering with elements” of a container because they depend on elements of the container not being replaced.]
- 8/2 {AI95-00302-03} A subprogram is said to *tamper with cursors* of a set object *S* if:
- 9/2
- it inserts or deletes elements of *S*, that is, it calls the Insert, Include, Clear, Delete, Exclude, or Replace_Element procedures with *S* as a parameter; or
- 9.a/2 **To be honest:** Operations which are defined to be equivalent to a call on one of these operations also are included. Similarly, operations which call one of these as part of their definition are included.
- 9.b/2 **Discussion:** We have to include Replace_Element here because it might delete and reinsert the element if it moves in the set. That could change the order of iteration, which is what this check is designed to prevent. Replace is also included, as it is defined in terms of Replace_Element.
- 10/2
- it finalizes *S*; or
- 10.1/3
- {AI05-0001-1} it calls the Assign procedure with *S* as the Target parameter; or
- 10.a/3 **Ramification:** We don't need to explicitly mention assignment_statement, because that finalizes the target object as part of the operation, and finalization of an object is already defined as tampering with cursors.
- 11/2
- it calls the Move procedure with *S* as a parameter; or
- 12/2
- it calls one of the operations defined to tamper with cursors of *S*.
- 13/2 {AI95-00302-03} A subprogram is said to *tamper with elements* of a set object *S* if:
- 14/2
- it tampers with cursors of *S*.
- 14.a/2 **Reason:** Complete replacement of an element can cause its memory to be deallocated while another operation is holding onto a reference to it. That can't be allowed. However, a simple modification of (part of) an element is not a problem, so Update_Element_Preserving_Key does not cause a problem.
- 14.b/2 We don't need to list Replace and Replace_Element here because they are covered by “tamper with cursors”. For Set, “tamper with cursors” and “tamper with elements” are the same. We leave both terms so that the rules for routines like Iterate and Query_Element are consistent across all containers.
- 14.1/3 {AI05-0265-1} When tampering with cursors is *prohibited* for a particular set object *S*, Program_Error is propagated by a call of any language-defined subprogram that is defined to tamper with the cursors of *S*, leaving *S* unmodified. Similarly, when tampering with elements is *prohibited* for a particular set object *S*, Program_Error is propagated by a call of any language-defined subprogram that is defined to tamper with the elements of *S* [(or tamper with the cursors of *S*)], leaving *S* unmodified.
- 14.c/3 **Proof:** Tampering with elements includes tampering with cursors, so we mention it only from completeness in the second sentence.
- 15/2 {AI95-00302-03} Empty_Set represents the empty Set object. It has a length of 0. If an object of type Set is not otherwise initialized, it is initialized to the same value as Empty_Set.
- 16/2 {AI95-00302-03} No_Element represents a cursor that designates no element. If an object of type Cursor is not otherwise initialized, it is initialized to the same value as No_Element.

<i>{AI95-00302-03}</i> The predefined "=" operator for type <code>Cursor</code> returns <code>True</code> if both cursors are <code>No_Element</code> , or designate the same element in the same container.	17/2
<i>{AI95-00302-03}</i> Execution of the default implementation of the <code>Input</code> , <code>Output</code> , <code>Read</code> , or <code>Write</code> attribute of type <code>Cursor</code> raises <code>Program_Error</code> .	18/2
Reason: A cursor will probably be implemented in terms of one or more access values, and the effects of streaming access values is unspecified. Rather than letting the user stream junk by accident, we mandate that streaming of cursors raise <code>Program_Error</code> by default. The attributes can always be specified if there is a need to support streaming.	18.a/2
<i>{AI05-0001-1}</i> <i>{AI05-0262-1}</i> <code>Set'Write</code> for a <code>Set</code> object <i>S</i> writes <code>Length(S)</code> elements of the set to the stream. It also may write additional information about the set.	18.1/3
<i>{AI05-0001-1}</i> <i>{AI05-0262-1}</i> <code>Set'Read</code> reads the representation of a set from the stream, and assigns to <i>Item</i> a set with the same length and elements as was written by <code>Set'Write</code> .	18.2/3
Ramification: Streaming more elements than the container length is wrong. For implementation implications of this rule, see the Implementation Note in A.18.2.	18.b/3
function <code>Has_Element</code> (<code>Position</code> : <code>Cursor</code>) return <code>Boolean</code> ;	18.3/3
<i>{AI05-0212-1}</i> Returns <code>True</code> if <code>Position</code> designates an element, and returns <code>False</code> otherwise.	18.4/3
To be honest: <i>{AI05-0005-1}</i> <i>{AI05-0212-1}</i> This function might not detect cursors that designate deleted elements; such cursors are invalid (see below) and the result of calling <code>Has_Element</code> with an invalid cursor is unspecified (but not erroneous).	18.c/3
function <code>"=</code> (<code>Left</code> , <code>Right</code> : <code>Set</code>) return <code>Boolean</code> ;	19/2
<i>{AI95-00302-03}</i> If <code>Left</code> and <code>Right</code> denote the same set object, then the function returns <code>True</code> . If <code>Left</code> and <code>Right</code> have different lengths, then the function returns <code>False</code> . Otherwise, for each element <i>E</i> in <code>Left</code> , the function returns <code>False</code> if an element equal to <i>E</i> (using the generic formal equality operator) is not present in <code>Right</code> . If the function has not returned a result after checking all of the elements, it returns <code>True</code> . Any exception raised during evaluation of element equality is propagated.	20/2
Implementation Note: This wording describes the canonical semantics. However, the order and number of calls on the formal equality function is unspecified for all of the operations that use it in this package, so an implementation can call it as many or as few times as it needs to get the correct answer. Specifically, there is no requirement to call the formal equality additional times once the answer has been determined.	20.a/2
function <code>Equivalent_Sets</code> (<code>Left</code> , <code>Right</code> : <code>Set</code>) return <code>Boolean</code> ;	21/2
<i>{AI95-00302-03}</i> If <code>Left</code> and <code>Right</code> denote the same set object, then the function returns <code>True</code> . If <code>Left</code> and <code>Right</code> have different lengths, then the function returns <code>False</code> . Otherwise, for each element <i>E</i> in <code>Left</code> , the function returns <code>False</code> if an element equivalent to <i>E</i> is not present in <code>Right</code> . If the function has not returned a result after checking all of the elements, it returns <code>True</code> . Any exception raised during evaluation of element equivalence is propagated.	22/2
function <code>To_Set</code> (<code>New_Item</code> : <code>Element_Type</code>) return <code>Set</code> ;	23/2
<i>{AI95-00302-03}</i> Returns a set containing the single element <code>New_Item</code> .	24/2
function <code>Length</code> (<code>Container</code> : <code>Set</code>) return <code>Count_Type</code> ;	25/2
<i>{AI95-00302-03}</i> Returns the number of elements in <code>Container</code> .	26/2
function <code>Is_Empty</code> (<code>Container</code> : <code>Set</code>) return <code>Boolean</code> ;	27/2
<i>{AI95-00302-03}</i> Equivalent to <code>Length (Container) = 0</code> .	28/2
procedure <code>Clear</code> (<code>Container</code> : in out <code>Set</code>);	29/2
<i>{AI95-00302-03}</i> Removes all the elements from <code>Container</code> .	30/2

- 31/2 **function** Element (Position : Cursor) **return** Element_Type;
- 32/2 {AI95-00302-03} If Position equals No_Element, then Constraint_Error is propagated. Otherwise, Element returns the element designated by Position.
- 33/2 **procedure** Replace_Element (Container : **in out** Set;
 Position : **in** Cursor;
 New_Item : **in** Element_Type);
- 34/2 {AI95-00302-03} If Position equals No_Element, then Constraint_Error is propagated; if Position does not designate an element in Container, then Program_Error is propagated. If an element equivalent to New_Item is already present in Container at a position other than Position, Program_Error is propagated. Otherwise, Replace_Element assigns New_Item to the element designated by Position. Any exception raised by the assignment is propagated.
- 34.a/2 **Implementation Note:** The final assignment may require that the node of the element be moved in the Set's data structures. That could mean that implementing this operation exactly as worded above could require the overhead of searching twice. Implementations are encouraged to avoid this extra overhead when possible, by prechecking if the old element is equivalent to the new one, by inserting a placeholder node while checking for an equivalent element, and similar optimizations.
- 34.b/2 The cursor still designates the same element after this operation; only the value of that element has changed. Cursors cannot include information about the relative position of an element in a Set (as they must survive insertions and deletions of other elements), so this should not pose an implementation hardship.
- 35/2 **procedure** Query_Element
 (Position : **in** Cursor;
 Process : **not null access procedure** (Element : **in** Element_Type));
- 36/3 {AI95-00302-03} {AI05-0021-1} {AI05-0265-1} If Position equals No_Element, then Constraint_Error is propagated. Otherwise, Query_Element calls Process.all with the element designated by Position as the argument. Tampering with the elements of the set that contains the element designated by Position is prohibited during the execution of the call on Process.all. Any exception raised by Process.all is propagated.
- 36.1/3 **type** Constant_Reference_Type
 (Element : **not null access constant** Element_Type) **is private**
 with Implicit_Dereference => Element;
- 36.2/3 {AI05-0212-1} The type Constant_Reference_Type needs finalization.
- 36.3/3 The default initialization of an object of type Constant_Reference_Type propagates Program_Error.
- 36.a/3 **Reason:** It is expected that Constant_Reference_Type will be a controlled type, for which finalization will have some action to terminate the tampering check for the associated container. If the object is created by default, however, there is no associated container. Since this is useless, and supporting this case would take extra work, we define it to raise an exception.
- 36.4/3 **function** Constant_Reference (Container : **aliased in** Set;
 Position : **in** Cursor)
 return Constant_Reference_Type;
- 36.5/3 {AI05-0212-1} {AI05-0269-1} This function (combined with the Constant_Indexing and Implicit_Dereference aspects) provides a convenient way to gain read access to an individual element of a set given a cursor.
- 36.6/3 {AI05-0212-1} {AI05-0265-1} If Position equals No_Element, then Constraint_Error is propagated; if Position does not designate an element in Container, then Program_Error is propagated. Otherwise, Constant_Reference returns an object whose discriminant is an access value that designates the element designated by Position. Tampering with the elements of Container is prohibited while the object returned by Constant_Reference exists and has not been finalized.

procedure Assign (Target : in out Set; Source : in Set);	36.7/3
{AI05-0001-1} {AI05-0248-1} If Target denotes the same object as Source, the operation has no effect. Otherwise, the elements of Source are copied to Target as for an <code>assignment_statement</code> assigning Source to Target.	36.8/3
Discussion: {AI05-0005-1} This routine exists for compatibility with the bounded set containers. For an unbounded set, <code>Assign(A, B)</code> and <code>A := B</code> behave identically. For a bounded set, <code>:=</code> will raise an exception if the container capacities are different, while <code>Assign</code> will not raise an exception if there is enough room in the target.	36.b/3
procedure Move (Target : in out Set; Source : in out Set);	37/2
{AI95-00302-03} {AI05-0001-1} {AI05-0248-1} {AI05-0262-1} If Target denotes the same object as Source, then the operation has no effect. Otherwise, the operation is equivalent to <code>Assign(Target, Source)</code> followed by <code>Clear(Source)</code> .	38/3
procedure Insert (Container : in out Set; New_Item : in Element_Type; Position : out Cursor; Inserted : out Boolean);	39/2
{AI95-00302-03} <code>Insert</code> checks if an element equivalent to <code>New_Item</code> is already present in <code>Container</code> . If a match is found, <code>Inserted</code> is set to <code>False</code> and <code>Position</code> designates the matching element. Otherwise, <code>Insert</code> adds <code>New_Item</code> to <code>Container</code> ; <code>Inserted</code> is set to <code>True</code> and <code>Position</code> designates the newly-inserted element. Any exception raised during allocation is propagated and <code>Container</code> is not modified.	40/2
procedure Insert (Container : in out Set; New_Item : in Element_Type);	41/2
{AI95-00302-03} <code>Insert</code> inserts <code>New_Item</code> into <code>Container</code> as per the four-parameter <code>Insert</code> , with the difference that if an element equivalent to <code>New_Item</code> is already in the set, then <code>Constraint_Error</code> is propagated.	42/2
Discussion: This is equivalent to:	42.a/2
declare	42.b/2
Inserted : Boolean; C : Cursor;	
begin	
Insert (Container, New_Item, C, Inserted);	
if not Inserted then	
raise Constraint_Error;	
end if;	
end;	
but doesn't require the hassle of out parameters.	42.c/2
procedure Include (Container : in out Set; New_Item : in Element_Type);	43/2
{AI95-00302-03} <code>Include</code> inserts <code>New_Item</code> into <code>Container</code> as per the four-parameter <code>Insert</code> , with the difference that if an element equivalent to <code>New_Item</code> is already in the set, then it is replaced. Any exception raised during assignment is propagated.	44/2
procedure Replace (Container : in out Set; New_Item : in Element_Type);	45/2
{AI95-00302-03} <code>Replace</code> checks if an element equivalent to <code>New_Item</code> is already in the set. If a match is found, that element is replaced with <code>New_Item</code> ; otherwise, <code>Constraint_Error</code> is propagated.	46/2

- 47/2 **procedure** Exclude (Container : **in out** Set;
 Item : **in** Element_Type);
- 48/2 {AI95-00302-03} Exclude checks if an element equivalent to Item is present in Container. If a match is found, Exclude removes the element from the set.
- 49/2 **procedure** Delete (Container : **in out** Set;
 Item : **in** Element_Type);
- 50/2 {AI95-00302-03} Delete checks if an element equivalent to Item is present in Container. If a match is found, Delete removes the element from the set; otherwise, Constraint_Error is propagated.
- 51/2 **procedure** Delete (Container : **in out** Set;
 Position : **in out** Cursor);
- 52/2 {AI95-00302-03} If Position equals No_Element, then Constraint_Error is propagated. If Position does not designate an element in Container, then Program_Error is propagated. Otherwise, Delete removes the element designated by Position from the set. Position is set to No_Element on return.
- 52.a/2 **Ramification:** The check on Position checks that the cursor does not belong to some other set. This check implies that a reference to the set is included in the cursor value. This wording is not meant to require detection of dangling cursors; such cursors are defined to be invalid, which means that execution is erroneous, and any result is allowed (including not raising an exception).
- 53/2 **procedure** Union (Target : **in out** Set;
 Source : **in** Set);
- 54/2 {AI95-00302-03} Union inserts into Target the elements of Source that are not equivalent to some element already in Target.
- 54.a/2 **Implementation Note:** If the objects are the same, the result is the same as the original object. The implementation needs to take care so that aliasing effects do not make the result trash; Union (S, S); must work.
- 55/2 **function** Union (Left, Right : Set) **return** Set;
- 56/2 {AI95-00302-03} Returns a set comprising all of the elements of Left, and the elements of Right that are not equivalent to some element of Left.
- 57/2 **procedure** Intersection (Target : **in out** Set;
 Source : **in** Set);
- 58/3 {AI95-00302-03} {AI05-0004-1} Intersection deletes from Target the elements of Target that are not equivalent to some element of Source.
- 58.a/2 **Implementation Note:** If the objects are the same, the result is the same as the original object. The implementation needs to take care so that aliasing effects do not make the result trash; Intersection (S, S); must work.
- 59/2 **function** Intersection (Left, Right : Set) **return** Set;
- 60/2 {AI95-00302-03} Returns a set comprising all the elements of Left that are equivalent to the some element of Right.
- 61/2 **procedure** Difference (Target : **in out** Set;
 Source : **in** Set);
- 62/2 {AI95-00302-03} If Target denotes the same object as Source, then Difference clears Target. Otherwise, it deletes from Target the elements that are equivalent to some element of Source.
- 63/2 **function** Difference (Left, Right : Set) **return** Set;
- 64/2 {AI95-00302-03} Returns a set comprising the elements of Left that are not equivalent to some element of Right.

procedure Symmetric_Difference (Target : in out Set; Source : in Set);	65/2
{AI95-00302-03} If Target denotes the same object as Source, then Symmetric_Difference clears Target. Otherwise, it deletes from Target the elements that are equivalent to some element of Source, and inserts into Target the elements of Source that are not equivalent to some element of Target.	66/2
function Symmetric_Difference (Left, Right : Set) return Set;	67/2
{AI95-00302-03} Returns a set comprising the elements of Left that are not equivalent to some element of Right, and the elements of Right that are not equivalent to some element of Left.	68/2
function Overlap (Left, Right : Set) return Boolean;	69/2
{AI95-00302-03} {AI05-0264-1} If an element of Left is equivalent to some element of Right, then Overlap returns True. Otherwise, it returns False.	70/3
Discussion: This operation is commutative. If Overlap returns False, the two sets are disjoint.	70.a/2
function Is_Subset (Subset : Set; Of_Set : Set) return Boolean;	71/2
{AI95-00302-03} {AI05-0264-1} If an element of Subset is not equivalent to some element of Of_Set, then Is_Subset returns False. Otherwise, it returns True.	72/3
Discussion: This operation is not commutative, so we use parameter names that make it clear in named notation which set is which.	72.a/2
function First (Container : Set) return Cursor;	73/2
{AI95-00302-03} If Length (Container) = 0, then First returns No_Element. Otherwise, First returns a cursor that designates the first element in Container.	74/2
function Next (Position : Cursor) return Cursor;	75/2
{AI95-00302-03} Returns a cursor that designates the successor of the element designated by Position. If Position designates the last element, then No_Element is returned. If Position equals No_Element, then No_Element is returned.	76/2
procedure Next (Position : in out Cursor);	77/2
{AI95-00302-03} Equivalent to Position := Next (Position).	78/2
<i>This paragraph was deleted.</i> {AI95-00302-03} {AI05-0004-1}	79/3
function Find (Container : Set; Item : Element_Type) return Cursor;	80/2
{AI95-00302-03} If Length (Container) equals 0, then Find returns No_Element. Otherwise, Find checks if an element equivalent to Item is present in Container. If a match is found, a cursor designating the matching element is returned; otherwise, No_Element is returned.	81/2
function Contains (Container : Set; Item : Element_Type) return Boolean;	82/2
{AI05-0004-1} Equivalent to Find (Container, Item) /= No_Element.	82.1/3
<i>Paragraphs 83 and 84 were moved above.</i>	
procedure Iterate (Container : in Set; Process : not null access procedure (Position : in Cursor));	85/2
{AI95-00302-03} {AI05-0265-1} Iterate calls Process.all with a cursor that designates each element in Container, starting with the first element and moving the cursor according to the	86/3

successor relation. Tampering with the cursors of Container is prohibited during the execution of a call on Process.all. Any exception raised by Process.all is propagated.

- 86.a/2 **Implementation Note:** The “tamper with cursors” check takes place when the operations that insert or delete elements, and so on are called.
- 86.b/2 See Iterate for vectors (A.18.2) for a suggested implementation of the check.
- 87/2 {AI95-00302-03} Both Containers.Hash_Set and Containers.Ordered_Set declare a nested generic package Generic_Keys, which provides operations that allow set manipulation in terms of a key (typically, a portion of an element) instead of a complete element. The formal function Key of Generic_Keys extracts a key value from an element. It is expected to return the same value each time it is called with a particular element. The behavior of Generic_Keys is unspecified if Key behaves in some other manner.
- 88/2 {AI95-00302-03} A key is expected to unambiguously determine a single equivalence class for elements. The behavior of Generic_Keys is unspecified if the formal parameters of this package behave in some other manner.
- 89/2 **function** Key (Position : Cursor) **return** Key_Type;
- 90/2 {AI95-00302-03} Equivalent to Key (Element (Position)).
- 91/2 {AI95-00302-03} The subprograms in package Generic_Keys named Contains, Find, Element, Delete, and Exclude, are equivalent to the corresponding subprograms in the parent package, with the difference that the Key parameter is used to locate an element in the set.
- 92/2 **procedure** Replace (Container : **in out** Set;
 Key : **in** Key_Type;
 New_Item : **in** Element_Type);
- 93/2 {AI95-00302-03} Equivalent to Replace_Element (Container, Find (Container, Key), New_Item).
- 94/2 **procedure** Update_Element_Preserving_Key
 (Container : **in out** Set;
 Position : **in** Cursor;
 Process : **not null access procedure**
 (Element : **in out** Element_Type));
- 95/3 {AI95-00302-03} {AI05-0265-1} If Position equals No_Element, then Constraint_Error is propagated; if Position does not designate an element in Container, then Program_Error is propagated. Otherwise, Update_Element_Preserving_Key uses Key to save the key value *K* of the element designated by Position. Update_Element_Preserving_Key then calls Process.all with that element as the argument. Tampering with the elements of Container is prohibited during the execution of the call on Process.all. Any exception raised by Process.all is propagated. After Process.all returns, Update_Element_Preserving_Key checks if *K* determines the same equivalence class as that for the new element; if not, the element is removed from the set and Program_Error is propagated.
- 95.a/2 **Reason:** The key check ensures that the invariants of the set are preserved by the modification. The “tampers with the elements” check prevents data loss (if Element_Type is by-copy) or erroneous execution (if element type is unconstrained and indefinite).
- 96/2 If Element_Type is unconstrained and definite, then the actual Element parameter of Process.all shall be unconstrained.
- 96.a/2 **Ramification:** This means that the elements cannot be directly allocated from the heap; it must be possible to change the discriminants of the element in place.
- 96.1/3 **type** Reference_Type (Element : **not null access** Element_Type) **is private**
 with Implicit_Dereference => Element;
- 96.2/3 {AI05-0212-1} The type Reference_Type needs finalization.

- The default initialization of an object of type `Reference_Type` propagates `Program_Error`. 96.3/3
- ```
function Reference_Preserving_Key (Container : aliased in out Set;
 Position : in Cursor)
return Reference_Type;
96.4/3
```
- {AI05-0212-1} {AI05-0269-1} This function (combined with the `Implicit_Dereference` aspect) provides a convenient way to gain read and write access to an individual element of a set given a cursor. 96.5/3
- {AI05-0212-1} {AI05-0265-1} If `Position` equals `No_Element`, then `Constraint_Error` is propagated; if `Position` does not designate an element in `Container`, then `Program_Error` is propagated. Otherwise, `Reference_Preserving_Key` uses `Key` to save the key value  $K$ ; then returns an object whose discriminant is an access value that designates the element designated by `Position`. Tampering with the elements of `Container` is prohibited while the object returned by `Reference_Preserving_Key` exists and has not been finalized. When the object returned by `Reference_Preserving_Key` is finalized, a check is made if  $K$  determines the same equivalence class as that for the new element; if not, the element is removed from the set and `Program_Error` is propagated. 96.6/3
- ```
function Constant_Reference (Container : aliased in Set;
                             Key       : in Key_Type)
return Constant_Reference_Type;
96.7/3
```
- {AI05-0212-1} {AI05-0269-1} This function (combined with the `Implicit_Dereference` aspect) provides a convenient way to gain read access to an individual element of a set given a key value. 96.8/3
- Equivalent to `Constant_Reference (Container, Find (Container, Key))`. 96.9/3
- ```
function Reference_Preserving_Key (Container : aliased in out Set;
 Key : in Key_Type)
return Reference_Type;
96.10/3
```
- {AI05-0212-1} {AI05-0269-1} This function (combined with the `Implicit_Dereference` aspect) provides a convenient way to gain read and write access to an individual element of a set given a key value. 96.11/3
- Equivalent to `Reference_Preserving_Key (Container, Find (Container, Key))`. 96.12/3

*Bounded (Run-Time) Errors*

- {AI05-0022-1} {AI05-0248-1} It is a bounded error for the actual function associated with a generic formal subprogram, when called as part of an operation of a set package, to tamper with elements of any set parameter of the operation. Either `Program_Error` is raised, or the operation works as defined on the value of the set either prior to, or subsequent to, some or all of the modifications to the set. 96.13/3
- {AI05-0027-1} It is a bounded error to call any subprogram declared in the visible part of a set package when the associated container has been finalized. If the operation takes `Container` as an **in out** parameter, then it raises `Constraint_Error` or `Program_Error`. Otherwise, the operation either proceeds as it would for an empty container, or it raises `Constraint_Error` or `Program_Error`. 96.14/3

*Erroneous Execution*

- {AI95-00302-03} A `Cursor` value is *invalid* if any of the following have occurred since it was created: 97/2
- The set that contains the element it designates has been finalized; 98/2
  - {AI05-0160-1} The set that contains the element it designates has been used as the `Target` of a call to `Assign`, or as the `target` of an `assignment_statement`; 98.1/3

- 99/2 • The set that contains the element it designates has been used as the Source or Target of a call to Move; or
- 100/3 • *{AI05-0160-1}* *{AI05-0262-1}* The element it designates has been removed from the set that previously contained the element.
- 100.a/3 **Ramification:** *{AI05-0160-1}* This can happen directly via calls to Clear, Exclude, Delete, and Update\_Element\_Preserving\_Key, and indirectly via calls to procedures Intersection, Difference, and Symmetric\_Difference.
- 101/2 *{AI95-00302-03}* The result of "=" or Has\_Element is unspecified if these functions are called with an invalid cursor parameter. Execution is erroneous if any other subprogram declared in Containers.Hashing\_Sets or Containers.Ordered\_Sets is called with an invalid cursor parameter.
- 101.a/2 **Discussion:** The list above is intended to be exhaustive. In other cases, a cursor value continues to designate its original element. For instance, cursor values survive the insertion and deletion of other elements.
- 101.b/2 While it is possible to check for these cases, in many cases the overhead necessary to make the check is substantial in time or space. Implementations are encouraged to check for as many of these cases as possible and raise Program\_Error if detected.
- 101.1/3 *{AI05-0212-1}* Execution is erroneous if the set associated with the result of a call to Reference or Constant\_Reference is finalized before the result object returned by the call to Reference or Constant\_Reference is finalized.
- 101.c/3 **Reason:** Each object of Reference\_Type and Constant\_Reference\_Type probably contains some reference to the originating container. If that container is prematurely finalized (which is only possible via Unchecked\_Deallocation, as accessibility checks prevent passing a container to Reference that will not live as long as the result), the finalization of the object of Reference\_Type will try to access a nonexistent object. This is a normal case of a dangling pointer created by Unchecked\_Deallocation; we have to explicitly mention it here as the pointer in question is not visible in the specification of the type. (This is the same reason we have to say this for invalid cursors.)

*Implementation Requirements*

- 102/2 *{AI95-00302-03}* No storage associated with a Set object shall be lost upon assignment or scope exit.
- 103/3 *{AI95-00302-03}* *{AI05-0262-1}* The execution of an assignment\_statement for a set shall have the effect of copying the elements from the source set object to the target set object and changing the length of the target object to that of the source object.
- 103.a/3 **Implementation Note:** *{AI05-0298-1}* An assignment of a Set is a “deep” copy; that is the elements are copied as well as the data structures. We say “effect of” in order to allow the implementation to avoid copying elements immediately if it wishes. For instance, an implementation that avoided copying until one of the containers is modified would be allowed. (Note that this implementation would require care, see A.18.2 for more.)

*Implementation Advice*

- 104/2 *{AI95-00302-03}* Move should not copy elements, and should minimize copying of internal data structures.
- 104.a/2 **Implementation Advice:** Move for sets should not copy elements, and should minimize copying of internal data structures.
- 104.b/2 **Implementation Note:** Usually that can be accomplished simply by moving the pointer(s) to the internal data structures from the Source container to the Target container.
- 105/2 *{AI95-00302-03}* If an exception is propagated from a set operation, no storage should be lost, nor any elements removed from a set unless specified by the operation.
- 105.a/2 **Implementation Advice:** If an exception is propagated from a set operation, no storage should be lost, nor any elements removed from a set unless specified by the operation.
- 105.b/2 **Reason:** This is important so that programs can recover from errors. But we don't want to require heroic efforts, so we just require documentation of cases where this can't be accomplished.

*Wording Changes from Ada 95*

{AI95-00302-03} This description of sets is new; the extensions are documented with the specific packages. 105.c/2

*Extensions to Ada 2005*

{AI05-0212-1} Added reference support to make set containers more convenient to use. 105.d/3

*Wording Changes from Ada 2005*

{AI05-0001-1} Added procedure Assign; the extension and incompatibility is documented with the specific packages. 105.e/3

{AI05-0001-1} Generalized the definition of Move. Specified which elements are read/written by stream attributes. 105.f/3

{AI05-0022-1} **Correction:** Added a Bounded (Run-Time) Error to cover tampering by generic actual subprograms. 105.g/3

{AI05-0027-1} **Correction:** Added a Bounded (Run-Time) Error to cover access to finalized set containers. 105.h/3

{AI05-0160-1} **Correction:** Revised the definition of invalid cursors to cover missing (and new) cases. 105.i/3

{AI05-0265-1} **Correction:** Defined when a container prohibits tampering in order to more clearly define where the check is made and the exception raised. 105.j/3

## A.18.8 The Generic Package Containers.Hashing\_Sets

*Static Semantics*

{AI95-00302-03} The generic library package Containers.Hashing\_Sets has the following declaration: 1/2

```
{AI05-0084-1} {AI05-0212-1} with Ada.Iterator_Interfaces; 2/3
generic
```

```
 type Element_Type is private;
 with function Hash (Element : Element_Type) return Hash_Type;
 with function Equivalent_Elements (Left, Right : Element_Type)
 return Boolean;
```

```
 with function "=" (Left, Right : Element_Type) return Boolean is <>;
package Ada.Containers.Hashing_Sets is
 pragma Preelaborate(Hashing_Sets);
 pragma Remote_Types(Hashing_Sets);
```

```
{AI05-0212-1} type Set is tagged private 3/3
```

```
 with Constant_Indexing => Constant_Reference,
 Default_Iterator => Iterate,
 Iterator_Element => Element_Type;
```

```
 pragma Preelaborable_Initialization(Set);
```

```
 type Cursor is private; 4/2
```

```
 pragma Preelaborable_Initialization(Cursor);
```

```

| {AI05-0212-1} {AI05-0265-1} {AI05-0269-1} Iterate returns an iterator object (see 5.5.1) that will generate a value for a loop parameter (see 5.5.2) designating each element in Container, starting with the first element and moving the cursor according to the successor relation. Tampering with the cursors of Container is prohibited while the iterator object exists (in particular, in the sequence_of_statements of the loop_statement whose iterator_specification denotes this object). The iterator object needs finalization. | 85.2/3 |

86/2 {AI95-00302-03} For any element  $E$ , the actual function for the generic formal function `Generic_Keys.Hash` is expected to be such that  $\text{Hash}(E) = \text{Generic\_Keys.Hash}(\text{Key}(E))$ . If the actuals for `Key` or `Generic_Keys.Hash` behave in some other manner, the behavior of `Generic_Keys` is unspecified. Which subprograms of `Generic_Keys` call `Generic_Keys.Hash`, and how many times they call it, is unspecified.

87/2 {AI95-00302-03} For any two elements  $E1$  and  $E2$ , the boolean values `Equivalent_Elements(E1, E2)` and `Equivalent_Keys(Key(E1), Key(E2))` are expected to be equal. If the actuals for `Key` or `Equivalent_Keys` behave in some other manner, the behavior of `Generic_Keys` is unspecified. Which subprograms of `Generic_Keys` call `Equivalent_Keys`, and how many times they call it, is unspecified.

*Implementation Advice*

88/2 {AI95-00302-03} If  $N$  is the length of a set, the average time complexity of the subprograms `Insert`, `Include`, `Replace`, `Delete`, `Exclude` and `Find` that take an element parameter should be  $O(\log N)$ . The average time complexity of the subprograms that take a cursor parameter should be  $O(1)$ . The average time complexity of `Reserve_Capacity` should be  $O(N)$ .

88.a/2 **Implementation Advice:** The average time complexity of the `Insert`, `Include`, `Replace`, `Delete`, `Exclude` and `Find` operations of `Containers.Hashed_Sets` that take an element parameter should be  $O(\log N)$ . The average time complexity of the subprograms of `Containers.Hashed_Sets` that take a cursor parameter should be  $O(1)$ . The average time complexity of `Containers.Hashed_Sets.Reserve_Capacity` should be  $O(N)$ .

88.b/2 **Implementation Note:** {AI95-00302-03} See A.18.5, “The Generic Package `Containers.Hashed_Maps`” for implementation notes regarding some of the operations of this package.

*Extensions to Ada 95*

88.c/2 {AI95-00302-03} The generic package `Containers.Hashed_Sets` is new.

*Incompatibilities With Ada 2005*

88.d/3 {AI05-0001-1} Subprograms `Assign` and `Copy` are added to `Containers.Hashed_Sets`. If an instance of `Containers.Hashed_Sets` is referenced in a `use_clause`, and an entity  $E$  with the same `defining_identifier` as a new entity in `Containers.Hashed_Sets` is defined in a package that is also referenced in a `use_clause`, the entity  $E$  may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur.

*Extensions to Ada 2005*

88.e/3 {AI05-0212-1} Added iterator and indexing support to make hashed set containers more convenient to use.

*Wording Changes from Ada 2005*

88.f/3 {AI05-0044-1} **Correction:** Added wording to require the formal function be such that equal elements are also equivalent.

88.g/3 {AI05-0084-1} **Correction:** Added a pragma `Remote_Types` so that containers can be used in distributed programs.

## A.18.9 The Generic Package `Containers.Ordered_Sets`

*Static Semantics*

1/2 {AI95-00302-03} The generic library package `Containers.Ordered_Sets` has the following declaration:

 Key : in Key_Type)
 return Constant_Reference_Type;

```

```

73.4/3 {AI05-0212-1} function Reference_Preserving_Key (Container : aliased in out
Set;
 Key : in Key_Type)
 return Reference_Type;
74/2 end Generic_Keys;
75/2 private
76/2 ... -- not specified by the language
77/2 end Ada.Containers.Ordered_Sets;
78/2 {AI95-00302-03} Two elements E1 and E2 are equivalent if both E1 < E2 and E2 < E1 return False,
using the generic formal "<" operator for elements. Function Equivalent_Elements returns True if Left
and Right are equivalent, and False otherwise.
79/3 {AI95-00302-03} {AI05-0044-1} The actual function for the generic formal function "<" on
Element_Type values is expected to return the same value each time it is called with a particular pair of
key values. It should define a strict weak ordering relationship (see A.18). If the actual for "<" behaves in
some other manner, the behavior of this package is unspecified. Which subprograms of this package call
"<" and how many times they call it, is unspecified.
79.1/3 {AI05-0044-1} If the actual function for the generic formal function "=" returns True for any pair of
nonequivalent elements, then the behavior of the container function "=" is unspecified.
80/2 {AI95-00302-03} If the value of an element stored in a set is changed other than by an operation in this
package such that at least one of "<" or "=" give different results, the behavior of this package is
unspecified.
80.a/2 Discussion: See A.18.6, "The Generic Package Containers.Ordered_Maps" for a suggested implementation, and for
justification of the restrictions regarding "<" and "=". Note that sets only need to store elements, not key/element pairs.
81/3 {AI95-00302-03} {AI05-0262-1} The first element of a nonempty set is the one which is less than all the
other elements in the set. The last element of a nonempty set is the one which is greater than all the other
elements in the set. The successor of an element is the smallest element that is larger than the given
element. The predecessor of an element is the largest element that is smaller than the given element. All
comparisons are done using the generic formal "<" operator for elements.
81.1/3 function Copy (Source : Set) return Set;
81.2/3 {AI05-0001-1} Returns a set whose elements are initialized from the corresponding elements of
Source.
82/2 procedure Delete_First (Container : in out Set);
83/3 {AI95-00302-03} {AI05-0264-1} If Container is empty, Delete_First has no effect. Otherwise,
the element designated by First (Container) is removed from Container. Delete_First tampers with
the cursors of Container.
84/2 procedure Delete_Last (Container : in out Set);
85/3 {AI95-00302-03} {AI05-0264-1} If Container is empty, Delete_Last has no effect. Otherwise, the
element designated by Last (Container) is removed from Container. Delete_Last tampers with the
cursors of Container.
86/2 function First_Element (Container : Set) return Element_Type;
87/2 {AI95-00302-03} Equivalent to Element (First (Container)).
88/2 function Last (Container : Set) return Cursor;
89/2 {AI95-00302-03} Returns a cursor that designates the last element in Container. If Container is
empty, returns No_Element.

```

| {AI95-00302-03} {AI05-0212-1} Iterates over the elements in Container as per procedure Iterate, with the difference that the elements are traversed in predecessor order, starting with the last element.                                                                              | 113/3   |
| <b>function</b> Iterate (Container : <b>in</b> Set)<br><b>return</b> Set_Iterator_Interfaces.Reversible_Iterator'Class;                                                                                                                                                                | 113.1/3 |
| {AI05-0212-1} {AI05-0265-1} {AI05-0269-1} Iterate returns a reversible iterator object (see 5.5.1) that will generate a value for a loop parameter (see 5.5.2) designating each element in                                                                                             | 113.2/3 |

Container, starting with the first element and moving the cursor according to the successor relation when used as a forward iterator, and starting with the last element and moving the cursor according to the predecessor relation when used as a reverse iterator. Tampering with the cursors of Container is prohibited while the iterator object exists (in particular, in the `sequence_of_statements` of the `loop_statement` whose `iterator_specification` denotes this object). The iterator object needs finalization.

113.3/3 **function** Iterate (Container : in Set; Start : in Cursor)  
**return** Set\_Iterator\_Interfaces.Reversible\_Iterator'Class;

113.4/3 {AI05-0262-1} {AI05-0265-1} {AI05-0269-1} If Start is not No\_Element and does not designate an item in Container, then Program\_Error is propagated. If Start is No\_Element, then Constraint\_Error is propagated. Otherwise, Iterate returns a reversible iterator object (see 5.5.1) that will generate a value for a loop parameter (see 5.5.2) designating each element in Container, starting with the element designated by Start and moving the cursor according to the successor relation when used as a forward iterator, or moving the cursor according to the predecessor relation when used as a reverse iterator. Tampering with the cursors of Container is prohibited while the iterator object exists (in particular, in the `sequence_of_statements` of the `loop_statement` whose `iterator_specification` denotes this object). The iterator object needs finalization.

113.a/3 **Discussion:** Exits are allowed from the loops created using the iterator objects. In particular, to stop the iteration at a particular cursor, just add

113.b/3 **exit when** Cur = Stop;

113.c/3 in the body of the loop (assuming that Cur is the loop parameter and Stop is the cursor that you want to stop at).

114/2 {AI95-00302-03} For any two elements *E1* and *E2*, the boolean values (*E1* < *E2*) and (Key(*E1*) < Key(*E2*)) are expected to be equal. If the actuals for Key or Generic\_Keys."<" behave in some other manner, the behavior of this package is unspecified. Which subprograms of this package call Key and Generic\_Keys."<", and how many times the functions are called, is unspecified.

115/2 {AI95-00302-03} In addition to the semantics described in A.18.7, the subprograms in package Generic\_Keys named Floor and Ceiling, are equivalent to the corresponding subprograms in the parent package, with the difference that the Key subprogram parameter is compared to elements in the container using the Key and "<" generic formal functions. The function named Equivalent\_Keys in package Generic\_Keys returns True if both Left < Right and Right < Left return False using the generic formal "<" operator, and returns True otherwise.

#### *Implementation Advice*

116/2 {AI95-00302-03} If *N* is the length of a set, then the worst-case time complexity of the Insert, Include, Replace, Delete, Exclude and Find operations that take an element parameter should be  $O((\log N)**2)$  or better. The worst-case time complexity of the subprograms that take a cursor parameter should be  $O(1)$ .

116.a/2 **Implementation Advice:** The worst-case time complexity of the Insert, Include, Replace, Delete, Exclude and Find operations of Containers.Ordered\_Sets that take an element parameter should be  $O((\log N)**2)$ . The worst-case time complexity of the subprograms of Containers.Ordered\_Sets that take a cursor parameter should be  $O(1)$ .

116.b/2 **Implementation Note:** {AI95-00302-03} See A.18.6, “The Generic Package Containers.Ordered\_Maps” for implementation notes regarding some of the operations of this package.

#### *Extensions to Ada 95*

116.c/2 {AI95-00302-03} The generic package Containers.Ordered\_Sets is new.

#### *Incompatibilities With Ada 2005*

116.d/3 {AI05-0001-1} Subprograms Assign and Copy are added to Containers.Ordered\_Sets. If an instance of Containers.Ordered\_Sets is referenced in a `use_clause`, and an entity *E* with the same `defining_identifier` as a new

entity in Containers.Ordered\_Sets is defined in a package that is also referenced in a `use_clause`, the entity *E* may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur.

*Extensions to Ada 2005*

{AI05-0212-1} Added iterator and indexing support to make ordered set containers more convenient to use. 116.e/3

*Wording Changes from Ada 2005*

{AI05-0044-1} **Correction:** Added wording to require the formal function be such that equal elements are also equivalent. 116.f/3

{AI05-0044-1} **Correction:** Redefined "<" actuals to require a strict weak ordering; the old definition allowed indeterminant comparisons that would not have worked in a container. 116.g/3

{AI05-0084-1} **Correction:** Added a pragma `Remote_Types` so that containers can be used in distributed programs. 116.h/3

## A.18.10 The Generic Package Containers.Multiway\_Trees

{AI05-0136-1} The language-defined generic package Containers.Multiway\_Trees provides private types Tree and Cursor, and a set of operations for each type. A multiway tree container is well-suited to represent nested structures. 1/3

**Discussion:** {AI05-0136-1} This tree just provides a basic structure, and make no promises about balancing or other automatic organization. In this sense, it is different than the indexed (Map, Set) forms. Rather, it provides a building block on which to construct more complex and more specialized tree containers. 1.a/3

{AI05-0136-1} A multiway tree container object manages a tree of internal *nodes*, each of which contains an element and pointers to the parent, first child, last child, next (successor) sibling, and previous (predecessor) sibling internal nodes. A cursor designates a particular node within a tree (and by extension the element contained in that node, if any). A cursor keeps designating the same node (and element) as long as the node is part of the container, even if the node is moved within the container. 2/3

{AI05-0136-1} {AI05-0269-1} A *subtree* is a particular node (which *roots the subtree*) and all of its child nodes (including all of the children of the child nodes, recursively). There is a special node, the *root*, which is always present and has neither an associated element value nor any parent node. The root node provides a place to add nodes to an otherwise empty tree and represents the base of the tree. 3/3

{AI05-0136-1} {AI05-0269-1} A node that has no children is called a *leaf node*. The *ancestors* of a node are the node itself, its parent node, the parent of the parent node, and so on until a node with no parent is reached. Similarly, the *descendants* of a node are the node itself, its child nodes, the children of each child node, and so on. 4/3

{AI05-0136-1} {AI05-0262-1} {AI05-0269-1} The nodes of a subtree can be visited in several different orders. For a *depth-first order*, after visiting a node, the nodes of its child list are each visited in depth-first order, with each child node visited in natural order (first child to last child). 5/3

**Ramification:** For the depth-first order, when each child node is visited, the child list of the child node is visited before the next sibling of the child node is visited. 5.a/3

*Static Semantics*

{AI05-0136-1} The generic library package Containers.Multiway\_Trees has the following declaration: 6/3

```
{AI05-0136-1} {AI05-0212-1} with Ada.Iterator_Interfaces;
generic
 type Element_Type is private;
 with function "=" (Left, Right : Element_Type) return Boolean is <>;
package Ada.Containers.Multiway_Trees is
 pragma Preelaborate(Multiway_Trees);
 pragma Remote_Types(Multiway_Trees);
```

7/3

```

8/3 {AI05-0136-1} {AI05-0212-1} type Tree is tagged private
 with Constant_Indexing => Constant_Reference,
 Variable_Indexing => Reference,
 Default_Iterator => Iterate,
 Iterator_Element => Element_Type;
 pragma Preelaborable_Initialization(Tree);
9/3 type Cursor is private;
 pragma Preelaborable_Initialization(Cursor);
10/3 Empty_Tree : constant Tree;
11/3 No_Element : constant Cursor;
12/3 function Has_Element (Position : Cursor) return Boolean;
13/3 {AI05-0212-1} package Tree_Iterator_Interfaces is new
 Ada.Iterator_Interfaces (Cursor, Has_Element);
14/3 function Equal_Subtree (Left_Position : Cursor;
 Right_Position: Cursor) return Boolean;
15/3 function "=" (Left, Right : Tree) return Boolean;
16/3 function Is_Empty (Container : Tree) return Boolean;

```

55/3 procedure Splice_Subtree (Target : in out Tree;
 Parent : in Cursor;
 Before : in Cursor;
 Source : in out Tree;
 Position : in out Cursor);

56/3 procedure Splice_Subtree (Container: in out Tree;
 Parent : in Cursor;
 Before : in Cursor;
 Position : in Cursor);

57/3 procedure Splice_Children (Target : in out Tree;
 Target_Parent : in Cursor;
 Before : in Cursor;
 Source : in out Tree;
 Source_Parent : in Cursor);

58/3 procedure Splice_Children (Container : in out Tree;
 Target_Parent : in Cursor;
 Before : in Cursor;
 Source_Parent : in Cursor);

59/3 function Parent (Position : Cursor) return Cursor;

60/3 function First_Child (Parent : Cursor) return Cursor;

61/3 function First_Child_Element (Parent : Cursor) return Element_Type;

62/3 function Last_Child (Parent : Cursor) return Cursor;

63/3 function Last_Child_Element (Parent : Cursor) return Element_Type;

64/3 function Next_Sibling (Position : Cursor) return Cursor;

65/3 function Previous_Sibling (Position : Cursor) return Cursor;

66/3 procedure Next_Sibling (Position : in out Cursor);

67/3 procedure Previous_Sibling (Position : in out Cursor);

68/3 procedure Iterate_Children
 (Parent : in Cursor;
 Process : not null access procedure (Position : in Cursor));

69/3 procedure Reverse_Iterate_Children
 (Parent : in Cursor;
 Process : not null access procedure (Position : in Cursor));

70/3 {AI05-0212-1} function Iterate_Children (Container : in Tree; Parent : in
 Cursor)
 return Tree_Iterator_Interfaces.Reversible_Iterator'Class;

71/3 private
 ... -- not specified by the language
 end Ada.Containers.Multiway_Trees;

72/3 {AI05-0136-1} The actual function for the generic formal function "=" on Element_Type values is
 expected to define a reflexive and symmetric relationship and return the same result value each time it
 is called with a particular pair of values. If it behaves in some other manner, the functions Find,
 Reverse_Find, Equal_Subtree, and "=" on tree values return an unspecified value. The exact arguments
 and number of calls of this generic formal function by the functions Find, Reverse_Find, Equal_Subtree,
 and "=" on tree values are unspecified.

73/3 {AI05-0136-1} The type Tree is used to represent trees. The type Tree needs finalization (see 7.6).

74/3 {AI05-0136-1} {AI05-0248-1} Empty_Tree represents the empty Tree object. It contains only the root
 node (Node_Count (Empty_Tree) returns 1). If an object of type Tree is not otherwise initialized, it
 is initialized to the same value as Empty_Tree.

75/3 {AI05-0136-1} No_Element represents a cursor that designates no element. If an object of type Cursor is
 not otherwise initialized, it is initialized to the same value as No_Element.

```

- {AI05-0136-1} The predefined "=" operator for type Cursor returns True if both cursors are No\_Element, or designate the same element in the same container. 76/3
- {AI05-0136-1} Execution of the default implementation of the Input, Output, Read, or Write attribute of type Cursor raises Program\_Error. 77/3
- {AI05-0136-1} {AI05-0248-1} {AI05-0262-1} Tree'Write for a Tree object *T* writes Node\_Count(*T*) - 1 elements of the tree to the stream. It also may write additional information about the tree. 78/3
- {AI05-0136-1} {AI05-0248-1} {AI05-0262-1} Tree'Read reads the representation of a tree from the stream, and assigns to *Item* a tree with the same elements and structure as was written by Tree'Write. 79/3
- Ramification:** Streaming more elements than the container holds is wrong. For implementation implications of this rule, see the Implementation Note in A.18.2. 79.a/3
- {AI05-0136-1} [Some operations of this generic package have access-to-subprogram parameters. To ensure such operations are well-defined, they guard against certain actions by the designated subprogram. In particular, some operations check for "tampering with cursors" of a container because they depend on the set of elements of the container remaining constant, and others check for "tampering with elements" of a container because they depend on elements of the container not being replaced.] 80/3
- {AI05-0136-1} A subprogram is said to *tamper with cursors* of a tree object *T* if: 81/3
- it inserts or deletes elements of *T*, that is, it calls the Clear, Delete\_Leaf, Insert\_Child, Delete\_Children, Delete\_Subtree, or Copy\_Subtree procedures with *T* as a parameter; or 82/3
 

**To be honest:** Operations which are defined to be equivalent to a call on one of these operations also are included. Similarly, operations which call one of these as part of their definition are included. 82.a/3
  - {AI05-0136-1} {AI05-0248-1} it reorders the elements of *T*, that is, it calls the Splice\_Subtree or Splice\_Children procedures with *T* as a parameter; or 83/3
  - it finalizes *T*; or 84/3
  - it calls Assign with *T* as the Target parameter; or 85/3
 

**Ramification:** We don't need to explicitly mention assignment\_statement, because that finalizes the target object as part of the operation, and finalization of an object is already defined as tampering with cursors. 85.a.1/3
  - it calls the Move procedure with *T* as a parameter. 86/3
 

**Reason:** Swap copies elements rather than reordering them, so it doesn't tamper with cursors. 86.a/3
- {AI05-0136-1} A subprogram is said to *tamper with elements* of a tree object *T* if: 87/3
- it tampers with cursors of *T*; or 88/3
  - it replaces one or more elements of *T*, that is, it calls the Replace\_Element or Swap procedures with *T* as a parameter. 89/3
 

**Reason:** Complete replacement of an element can cause its memory to be deallocated while another operation is holding onto a reference to it. That can't be allowed. However, a simple modification of (part of) an element is not a problem, so Update\_Element does not cause a problem. 89.a/3

**Ramification:** Assign is defined in terms of Clear and Replace\_Element, so we don't need to mention it explicitly. Similarly, we don't need to explicitly mention assignment\_statement, because that finalizes the target object as part of the operation, and finalization of an object is already defined as tampering with the element. 89.a.1/3
- {AI05-0265-1} When tampering with cursors is *prohibited* for a particular tree object *T*, Program\_Error is propagated by a call of any language-defined subprogram that is defined to tamper with the cursors of *T*, leaving *T* unmodified. Similarly, when tampering with elements is *prohibited* for a particular tree object *T*, Program\_Error is propagated by a call of any language-defined subprogram that is defined to tamper with the elements of *T* [(or tamper with the cursors of *T*)], leaving *T* unmodified. 90/3
- Proof:** Tampering with elements includes tampering with cursors, so we mention it only from completeness in the second sentence. 90.a/3

- 91/3     **function** Has\_Element (Position : Cursor) **return** Boolean;
- 92/3         Returns True if Position designates an element, and returns False otherwise. [In particular, Has\_Element returns False if the cursor designates a root node or equals No\_Element.]
- 92.a/3     **To be honest:** {AI05-0005-1} {AI05-0136-1} This function might not detect cursors that designate deleted elements; such cursors are invalid (see below) and the result of calling Has\_Element with an invalid cursor is unspecified (but not erroneous).
- 93/3     **function** Equal\_Subtree (Left\_Position : Cursor;  
                                  Right\_Position: Cursor) **return** Boolean;
- 94/3         {AI05-0136-1} {AI05-0248-1} {AI05-0262-1} {AI05-0264-1} If Left\_Position or Right\_Position equals No\_Element, propagates Constraint\_Error. If the number of child nodes of the element designated by Left\_Position is different from the number of child nodes of the element designated by Right\_Position, the function returns False. If Left\_Position designates a root node and Right\_Position does not, the function returns False. If Right\_Position designates a root node and Left\_Position does not, the function returns False. Unless both cursors designate a root node, the elements are compared using the generic formal equality operator. If the result of the element comparison is False, the function returns False. Otherwise, it calls Equal\_Subtree on a cursor designating each child element of the element designated by Left\_Position and a cursor designating the corresponding child element of the element designated by Right\_Position. If any such call returns False, the function returns False; otherwise, it returns True. Any exception raised during the evaluation of element equality is propagated.
- 94.a/3     **Ramification:** Left\_Position and Right\_Position do not need to be from the same tree.
- 94.b/3     **Implementation Note:** This wording describes the canonical semantics. However, the order and number of calls on the formal equality function is unspecified for all of the operations that use it in this package, so an implementation can call it as many or as few times as it needs to get the correct answer. Similarly, a global rule (see the introduction of Annex A) says that language-defined routines are not affected by overriding of other language-defined routines. This means that no reasonable program can tell how many times Equal\_Subtree is called, and thus an implementation can call it as many or as few times as it needs to get the correct answer. Specifically, there is no requirement to call the formal equality or Equal\_Subtree additional times once the answer has been determined.
- 95/3     **function** "=" (Left, Right : Tree) **return** Boolean;
- 96/3         {AI05-0136-1} {AI05-0262-1} If Left and Right denote the same tree object, then the function returns True. Otherwise, it calls Equal\_Subtree with cursors designating the root nodes of Left and Right; the result is returned. Any exception raised during the evaluation of Equal\_Subtree is propagated.
- 96.a/3     **Implementation Note:** Similar considerations apply here as apply to Equal\_Subtree. The actual number of calls performed is unspecified.
- 97/3     **function** Node\_Count (Container : Tree) **return** Count\_Type;
- 98/3         {AI05-0136-1} Node\_Count returns the number of nodes in Container.
- 98.a/3     **Ramification:** Since all tree objects have a root node, this can never return a value of 0. Node\_Count (Some\_Tree) should always equal Subtree\_Node\_Count (Root (Some\_Tree)).
- 99/3     **function** Subtree\_Node\_Count (Position : Cursor) **return** Count\_Type;
- 100/3         {AI05-0136-1} {AI05-0248-1} If Position is No\_Element, Subtree\_Node\_Count returns 0; otherwise, Subtree\_Node\_Count returns the number of nodes in the subtree that is rooted by Position.
- 101/3     **function** Is\_Empty (Container : Tree) **return** Boolean;
- 102/3         {AI05-0136-1} Equivalent to Node\_Count (Container) = 1.
- 102.a/3     **Ramification:** An empty tree contains just the root node.

| {AI05-0136-1} Removes all the elements from Container.                                                                                                                                                                                                                                                                                                                                                                                                                                           | 112/3   |
| <b>Ramification:</b> The root node is not removed; all trees have a root node.                                                                                                                                                                                                                                                                                                                                                                                                                   | 112.a/3 |
| <b>function</b> Element (Position : Cursor) <b>return</b> Element_Type;                                                                                                                                                                                                                                                                                                                                                                                                                          | 113/3   |
| {AI05-0136-1} If Position equals No_Element, then Constraint_Error is propagated; if Position designates the root node of a tree, then Program_Error is propagated. Otherwise, Element returns the element designated by Position.                                                                                                                                                                                                                                                               | 114/3   |
| <b>Ramification:</b> The root node does not contain an element, so that value cannot be read or written.                                                                                                                                                                                                                                                                                                                                                                                         | 114.a/3 |
| <b>procedure</b> Replace_Element (Container : <b>in out</b> Tree;<br>Position : <b>in</b> Cursor;<br>New_Item : <b>in</b> Element_Type);                                                                                                                                                                                                                                                                                                                                                         | 115/3   |
| {AI05-0136-1} {AI05-0264-1} If Position equals No_Element, then Constraint_Error is propagated; if Position does not designate an element in Container (including if it designates the root node), then Program_Error is propagated. Otherwise, Replace_Element assigns the value New_Item to the element designated by Position.                                                                                                                                                                | 116/3   |
| <b>procedure</b> Query_Element<br>(Position : <b>in</b> Cursor;<br>Process : <b>not null access procedure</b> (Element : <b>in</b> Element_Type));                                                                                                                                                                                                                                                                                                                                               | 117/3   |
| {AI05-0136-1} {AI05-0265-1} If Position equals No_Element, then Constraint_Error is propagated; if Position designates the root node of a tree, then Program_Error is propagated. Otherwise, Query_Element calls Process.all with the element designated by Position as the argument. Tampering with the elements of the tree that contains the element designated by Position is prohibited during the execution of the call on Process.all. Any exception raised by Process.all is propagated. | 118/3   |

- 119/3     **procedure** Update\_Element  
           (Container : **in out** Tree;  
           Position : **in**    Cursor;  
           Process : **not null access procedure**  
                       (Element : **in out** Element\_Type));
- 120/3     {AI05-0136-1} {AI05-0264-1} {AI05-0265-1} If Position equals No\_Element, then Constraint\_Error is propagated; if Position does not designate an element in Container (including if it designates the root node), then Program\_Error is propagated. Otherwise, Update\_Element calls Process.all with the element designated by Position as the argument. Tampering with the elements of Container is prohibited during the execution of the call on Process.all. Any exception raised by Process.all is propagated.
- 121/3     If Element\_Type is unconstrained and definite, then the actual Element parameter of Process.all shall be unconstrained.
- 121.a/3    **Ramification:** This means that the elements cannot be directly allocated from the heap; it must be possible to change the discriminants of the element in place.
- 122/3     **type** Constant\_Reference\_Type  
           (Element : **not null access constant** Element\_Type) **is private**  
           with Implicit\_Dereference => Element;
- 123/3     **type** Reference\_Type (Element : **not null access** Element\_Type) **is private**  
           with Implicit\_Dereference => Element;
- 124/3     {AI05-0212-1} The types Constant\_Reference\_Type and Reference\_Type need finalization.
- 125/3     The default initialization of an object of type Constant\_Reference\_Type or Reference\_Type propagates Program\_Error.
- 125.a/3    **Reason:** It is expected that Reference\_Type (and Constant\_Reference\_Type) will be a controlled type, for which finalization will have some action to terminate the tampering check for the associated container. If the object is created by default, however, there is no associated container. Since this is useless, and supporting this case would take extra work, we define it to raise an exception.
- 126/3     **function** Constant\_Reference (Container : **aliased in** Tree;  
                                       Position : **in** Cursor)  
           **return** Constant\_Reference\_Type;
- 127/3     {AI05-0212-1} {AI05-0269-1} This function (combined with the Constant\_Indexing and Implicit\_Dereference aspects) provides a convenient way to gain read access to an individual element of a tree given a cursor.
- 128/3     {AI05-0212-1} {AI05-0265-1} If Position equals No\_Element, then Constraint\_Error is propagated; if Position does not designate an element in Container, then Program\_Error is propagated. Otherwise, Constant\_Reference returns an object whose discriminant is an access value that designates the element designated by Position. Tampering with the elements of Container is prohibited while the object returned by Constant\_Reference exists and has not been finalized.
- 129/3     **function** Reference (Container : **aliased in out** Tree;  
                               Position : **in** Cursor)  
           **return** Reference\_Type;
- 130/3     {AI05-0212-1} {AI05-0269-1} This function (combined with the Variable\_Indexing and Implicit\_Dereference aspects) provides a convenient way to gain read and write access to an individual element of a tree given a cursor.
- 131/3     {AI05-0212-1} {AI05-0265-1} If Position equals No\_Element, then Constraint\_Error is propagated; if Position does not designate an element in Container, then Program\_Error is propagated. Otherwise, Reference returns an object whose discriminant is an access value that

- designates the element designated by Position. Tampering with the elements of Container is prohibited while the object returned by Reference exists and has not been finalized.
- procedure** Assign (Target : in out Tree; Source : in Tree); 132/3
- {AI05-0136-1} {AI05-0248-1} If Target denotes the same object as Source, the operation has no effect. Otherwise, the elements of Source are copied to Target as for an assignment\_statement assigning Source to Target. 133/3
- Ramification:** Each element in Target has a parent element that corresponds to the parent element of the Source element, and has child elements that correspond to the child elements of the Source element. 133.a/3
- Discussion:** {AI05-0005-1} This routine exists for compatibility with the bounded tree container. For an unbounded tree, Assign(A, B) and A := B behave identically. For a bounded tree, := will raise an exception if the container capacities are different, while Assign will not raise an exception if there is enough room in the target. 133.b/3
- function** Copy (Source : Tree) return Tree; 134/3
- {AI05-0136-1} Returns a tree with the same structure as Source and whose elements are initialized from the corresponding elements of Source. 135/3
- procedure** Move (Target : in out Tree;  
Source : in out Tree); 136/3
- {AI05-0136-1} {AI05-0248-1} If Target denotes the same object as Source, then the operation has no effect. Otherwise, Move first calls Clear (Target). Then, the nodes other than the root node in Source are moved to Target (in the same positions). After Move completes, Node\_Count (Target) is the number of nodes originally in Source, and Node\_Count (Source) is 1. 137/3
- procedure** Delete\_Leaf (Container : in out Tree;  
Position : in out Cursor); 138/3
- {AI05-0136-1} {AI05-0248-1} If Position equals No\_Element, then Constraint\_Error is propagated; if Position does not designate an element in Container (including if it designates the root node), then Program\_Error is propagated. If the element designated by position has any child elements, then Constraint\_Error is propagated. Otherwise, Delete\_Leaf removes (from Container) the element designated by Position. Finally, Position is set to No\_Element. 139/3
- Ramification:** The check on Position checks that the cursor does not belong to some other Container. This check implies that a reference to the container is included in the cursor value. This wording is not meant to require detection of dangling cursors; such cursors are defined to be invalid, which means that execution is erroneous, and any result is allowed (including not raising an exception). 139.a/3
- The root node cannot be deleted. 139.b/3
- procedure** Delete\_Subtree (Container : in out Tree;  
Position : in out Cursor); 140/3
- {AI05-0136-1} {AI05-0264-1} {AI05-0269-1} If Position equals No\_Element, then Constraint\_Error is propagated. If Position does not designate an element in Container (including if it designates the root node), then Program\_Error is propagated. Otherwise, Delete\_Subtree removes (from Container) the subtree designated by Position (that is, all descendants of the node designated by Position including the node itself), and Position is set to No\_Element. 141/3
- Ramification:** The root node cannot be deleted. To delete the entire contents of the tree, call Clear(Container). 141.a/3
- procedure** Swap (Container : in out Tree;  
I, J : in Cursor); 142/3
- {AI05-0136-1} If either I or J equals No\_Element, then Constraint\_Error is propagated. If either I or J do not designate an element in Container (including if either designates the root node), then Program\_Error is propagated. Otherwise, Swap exchanges the values of the elements designated by I and J. 143/3

- 143.a/3 **Ramification:** After a call to `Swap`, `I` designates the element value previously designated by `J`, and `J` designates the element value previously designated by `I`. The position of the elements do not change; for instance, the parent node and the first child node of `I` are unchanged by the operation.
- 143.b/3 The root nodes do not contain element values, so they cannot be swapped.
- 143.c/3 **To be honest:** The implementation is not required to actually copy the elements if it can do the swap some other way. But it is allowed to copy the elements if needed.
- 144/3 **function** Find (Container : Tree;  
                  Item      : Element\_Type)  
          **return** Cursor;
- 145/3 {AI05-0136-1} {AI05-0262-1} Find searches the elements of Container for an element equal to Item (using the generic formal equality operator). The search starts at the root node. The search traverses the tree in a depth-first order. If no equal element is found, then Find returns No\_Element. Otherwise, it returns a cursor designating the first equal element encountered.
- 146/3 **function** Find\_In\_Subtree (Position : Cursor;  
                          Item      : Element\_Type)  
          **return** Cursor;
- 147/3 {AI05-0136-1} {AI05-0248-1} {AI05-0262-1} If Position equals No\_Element, then Constraint\_Error is propagated. Find\_In\_Subtree searches the subtree rooted by Position for an element equal to Item (using the generic formal equality operator). The search starts at the element designated by Position. The search traverses the subtree in a depth-first order. If no equal element is found, then Find returns No\_Element. Otherwise, it returns a cursor designating the first equal element encountered.
- 147.a/3 **Ramification:** Find\_In\_Subtree does not check any siblings of the element designated by Position. The root node does not contain an element, and therefore it can never be returned, but it can be explicitly passed to Position.
- 148/3 **function** Ancestor\_Find (Position : Cursor;  
                          Item      : Element\_Type)  
          **return** Cursor;
- 149/3 {AI05-0136-1} {AI05-0248-1} If Position equals No\_Element, then Constraint\_Error is propagated. Otherwise, Ancestor\_Find searches for an element equal to Item (using the generic formal equality operator). The search starts at the node designated by Position, and checks each ancestor proceeding toward the root of the subtree. If no equal element is found, then Ancestor\_Find returns No\_Element. Otherwise, it returns a cursor designating the first equal element encountered.
- 149.a/3 **Ramification:** {AI05-0248-1} No\_Element is returned if Position is the root node.
- 150/3 **function** Contains (Container : Tree;  
                  Item      : Element\_Type) **return** Boolean;
- 151/3 {AI05-0136-1} Equivalent to Find (Container, Item) /= No\_Element.
- 152/3 **procedure** Iterate  
(Container : **in** Tree;  
  Process  : **not null access procedure** (Position : **in** Cursor));
- 153/3 {AI05-0136-1} {AI05-0265-1} Iterate calls Process.all with a cursor that designates each element in Container, starting with the root node and proceeding in a depth-first order. Tampering with the cursors of Container is prohibited during the execution of a call on Process.all. Any exception raised by Process.all is propagated.
- 153.a/3 **Ramification:** Process is not called with the root node, which does not have an associated element.
- 153.b/3 **Implementation Note:** The purpose of the tamper with cursors check is to prevent erroneous execution from the Position parameter of Process.all becoming invalid. This check takes place when the operations that tamper with the cursors of the container are called. The check cannot be made later (say in the body of Iterate), because that could

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |         |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| cause the Position cursor to be invalid and potentially cause execution to become erroneous — defeating the purpose of the check.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |         |
| See Iterate for vectors (A.18.2) for a suggested implementation of the check.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 153.c/3 |

If Parent does not designate a node in Container, then Program\_Error is propagated. If Before is not equal to No\_Element, and does not designate a node in Container, then Program\_Error is propagated. If Before is not equal to No\_Element, and Parent does not designate the parent node of the node designated by Before, then Constraint\_Error is propagated. Otherwise, Insert\_Child allocates Count nodes, the elements contained in the new nodes are initialized by default (see 3.3.1), and the new nodes are inserted as children of Parent. If Parent already has child nodes, then the new nodes are inserted prior to the node designated by Before, or, if Before equals No\_Element, the new nodes are inserted after the last existing child node of Parent. Position designates the first newly-inserted node, or if Count equals 0, then Position is assigned the value of Before. Any exception raised during allocation of internal storage is propagated, and Container is not modified.

- procedure** Prepend\_Child (Container : **in out** Tree; 170/3  
                           Parent     : **in**        Cursor;  
                           New\_Item  : **in**        Element\_Type;  
                           Count     : **in**        Count\_Type := 1);
- {AI05-0136-1} Equivalent to Insert\_Child (Container, Parent, First\_Child (Container, Parent), 171/3  
 New\_Item, Count).
- procedure** Append\_Child (Container : **in out** Tree; 172/3  
                           Parent     : **in**        Cursor;  
                           New\_Item  : **in**        Element\_Type;  
                           Count     : **in**        Count\_Type := 1);
- {AI05-0136-1} {AI05-0269-1} Equivalent to Insert\_Child (Container, Parent, No\_Element, 173/3  
 New\_Item, Count).
- procedure** Delete\_Children (Container : **in out** Tree; 174/3  
                               Parent     : **in**        Cursor);
- {AI05-0136-1} If Parent equals No\_Element, then Constraint\_Error is propagated. If Parent does 175/3  
 not designate a node in Container, Program\_Error is propagated. Otherwise, Delete\_Children  
 removes (from Container) all of the descendants of Parent other than Parent itself.
- Discussion:** This routine deletes all of the child subtrees of Parent at once. Use Delete\_Subtree to delete an individual 175.a/3  
 subtree.
- procedure** Copy\_Subtree (Target     : **in out** Tree; 176/3  
                           Parent     : **in**        Cursor;  
                           Before     : **in**        Cursor;  
                           Source     : **in**        Cursor);
- {AI05-0136-1} {AI05-0248-1} {AI05-0262-1} If Parent equals No\_Element, then 177/3  
 Constraint\_Error is propagated. If Parent does not designate a node in Target, then  
 Program\_Error is propagated. If Before is not equal to No\_Element, and does not designate a  
 node in Target, then Program\_Error is propagated. If Before is not equal to No\_Element, and  
 Parent does not designate the parent node of the node designated by Before, then  
 Constraint\_Error is propagated. If Source designates a root node, then Constraint\_Error  
 is propagated. If Source is equal to No\_Element, then the operation has no effect. Otherwise,  
 the subtree rooted by Source (which can be from any tree; it does not have to be a subtree of  
 Target) is copied (new nodes are allocated to create a new subtree with the same structure as  
 the Source subtree, with each element initialized from the corresponding element of the  
 Source subtree) and inserted into Target as a child of Parent. If Parent already has child  
 nodes, then the new nodes are inserted prior to the node designated by Before, or, if  
 Before equals No\_Element, the new nodes are inserted after the last existing child node of  
 Parent. The parent of the newly created subtree is set to Parent, and the overall count of  
 Target is incremented by Subtree\_Node\_Count (Source). Any exception raised during  
 allocation of internal storage is propagated, and Container is not modified.
- Discussion:** We only need one routine here, as the source object is not modified, so we can use the same routine for 177.a/3  
 both copying within and between containers.
- Ramification:** We do not allow copying a subtree that includes a root node, as that would require inserting a node with 177.b/3  
 no value in the middle of the target tree. To copy an entire tree to another tree object, use Copy.
- procedure** Splice\_Subtree (Target     : **in out** Tree; 178/3  
                           Parent     : **in**        Cursor;  
                           Before     : **in**        Cursor;  
                           Source     : **in out** Tree;  
                           Position  : **in out** Cursor);
- {AI05-0136-1} {AI05-0248-1} {AI05-0262-1} {AI05-0269-1} If Parent equals No\_Element, then 179/3  
 Constraint\_Error is propagated. If Parent does not designate a node in Target, then

Program\_Error is propagated. If Before is not equal to No\_Element, and does not designate a node in Target, then Program\_Error is propagated. If Before is not equal to No\_Element, and Parent does not designate the parent node of the node designated by Before, then Constraint\_Error is propagated. If Position equals No\_Element, Constraint\_Error is propagated. If Position does not designate a node in Source or designates a root node, then Program\_Error is propagated. If Source denotes the same object as Target, then: if Position equals Before there is no effect; if Position designates an ancestor of Parent (including Parent itself), Constraint\_Error is propagated; otherwise, the subtree rooted by the element designated by Position is moved to be a child of Parent. If Parent already has child nodes, then the moved nodes are inserted prior to the node designated by Before, or, if Before equals No\_Element, the moved nodes are inserted after the last existing child node of Parent. In each of these cases, Position and the count of Target are unchanged, and the parent of the element designated by Position is set to Parent.

179.a/3 **Reason:** We can't allow moving the subtree of Position to a proper descendant node of the subtree, as the descendant node will be part of the subtree being moved. The result would be a circularly linked tree, or one with inaccessible nodes. Thus we have to check Position against Parent, even though such a check is  $O(\text{Depth}(\text{Source}))$ .

180/3 {AI05-0136-1} {AI05-0248-1} Otherwise (if Source does not denote the same object as Target), the subtree designated by Position is removed from Source and moved to Target. The subtree is inserted as a child of Parent. If Parent already has child nodes, then the moved nodes are inserted prior to the node designated by Before, or, if Before equals No\_Element, the moved nodes are inserted after the last existing child node of Parent. In each of these cases, the count of Target is incremented by Subtree\_Node\_Count (Position), and the count of Source is decremented by Subtree\_Node\_Count (Position), Position is updated to represent an element in Target.

180.a/3 **Ramification:** If Source is the same as Target, and Position = Before, or Next\_Sibling(Position) = Before, Splice\_Subtree has no effect, as the subtree does not have to move to meet the postcondition.

180.b/3 We do not allow splicing a subtree that includes a root node, as that would require inserting a node with no value in the middle of the target tree. Splice the children of the root node instead.

180.c/3 For this reason there is no operation to splice an entire tree, as that would necessarily involve splicing a root node.

181/3 **procedure** Splice\_Subtree (Container: **in out** Tree;  
                           Parent : **in** Cursor;  
                           Before : **in** Cursor;  
                           Position : **in** Cursor);

182/3 {AI05-0136-1} {AI05-0248-1} {AI05-0262-1} {AI05-0269-1} If Parent equals No\_Element, then Constraint\_Error is propagated. If Parent does not designate a node in Container, then Program\_Error is propagated. If Before is not equal to No\_Element, and does not designate a node in Container, then Program\_Error is propagated. If Before is not equal to No\_Element, and Parent does not designate the parent node of the node designated by Before, then Constraint\_Error is propagated. If Position equals No\_Element, Constraint\_Error is propagated. If Position does not designate a node in Container or designates a root node, then Program\_Error is propagated. If Position equals Before, there is no effect. If Position designates an ancestor of Parent (including Parent itself), Constraint\_Error is propagated. Otherwise, the subtree rooted by the element designated by Position is moved to be a child of Parent. If Parent already has child nodes, then the moved nodes are inserted prior to the node designated by Before, or, if Before equals No\_Element, the moved nodes are inserted after the last existing child node of Parent. The parent of the element designated by Position is set to Parent.

182.a/3 **Reason:** We can't allow moving the subtree of Position to a proper descendant node of the subtree, as the descendant node will be part of the subtree being moved.

```

procedure Splice_Children (Target : in out Tree; 183/3
 Target_Parent : in Cursor;
 Before : in Cursor;
 Source : in out Tree;
 Source_Parent : in Cursor);

```

*{AI05-0136-1}* *{AI05-0262-1}* If Target\_Parent equals No\_Element, then Constraint\_Error is propagated. If Target\_Parent does not designate a node in Target, then Program\_Error is propagated. If Before is not equal to No\_Element, and does not designate an element in Target, then Program\_Error is propagated. If Source\_Parent equals No\_Element, then Constraint\_Error is propagated. If Source\_Parent does not designate a node in Source, then Program\_Error is propagated. If Before is not equal to No\_Element, and Target\_Parent does not designate the parent node of the node designated by Before, then Constraint\_Error is propagated. 184/3

If Source denotes the same object as Target, then: 185/3

- if Target\_Parent equals Source\_Parent there is no effect; else 186/3
- *{AI05-0136-1}* *{AI05-0269-1}* if Source\_Parent is an ancestor of Target\_Parent other than Target\_Parent itself, then Constraint\_Error is propagated; else 187/3
- *{AI05-0136-1}* *{AI05-0248-1}* *{AI05-0269-1}* the child elements (and the further descendants) of Source\_Parent are moved to be child elements of Target\_Parent. If Target\_Parent already has child elements, then the moved elements are inserted prior to the node designated by Before, or, if Before equals No\_Element, the moved elements are inserted after the last existing child node of Target\_Parent. The parent of each moved child element is set to Target\_Parent. 188/3

**Reason:** We can't allow moving the children of Source\_Parent to a proper descendant node, as the descendant node will be part of one of the subtrees being moved. 188.a/3

*{AI05-0136-1}* *{AI05-0248-1}* *{AI05-0269-1}* Otherwise (if Source does not denote the same object as Target), the child elements (and the further descendants) of Source\_Parent are removed from Source and moved to Target. The child elements are inserted as children of Target\_Parent. If Target\_Parent already has child elements, then the moved elements are inserted prior to the node designated by Before, or, if Before equals No\_Element, the moved elements are inserted after the last existing child node of Target\_Parent. In each of these cases, the overall count of Target is incremented by Subtree\_Node\_Count (Source\_Parent)-1, and the overall count of Source is decremented by Subtree\_Node\_Count (Source\_Parent)-1. 189/3

**Ramification:** The node designated by Source\_Parent is not moved, thus we never need to update Source\_Parent. 189.a/3

Move (Target, Source) could be written Splice\_Children (Target, Target.Root, No\_Element, Source, Source.Root); 189.b/3

```

procedure Splice_Children (Container : in out Tree; 190/3
 Target_Parent : in Cursor;
 Before : in Cursor;
 Source_Parent : in Cursor);

```

*{AI05-0136-1}* *{AI05-0248-1}* *{AI05-0262-1}* *{AI05-0264-1}* *{AI05-0269-1}* If Target\_Parent equals No\_Element, then Constraint\_Error is propagated. If Target\_Parent does not designate a node in Container, then Program\_Error is propagated. If Before is not equal to No\_Element, and does not designate an element in Container, then Program\_Error is propagated. If Source\_Parent equals No\_Element, then Constraint\_Error is propagated. If Source\_Parent does not designate a node in Container, then Program\_Error is propagated. If Before is not equal to No\_Element, and Target\_Parent does not designate the parent node of the node designated by Before, then Constraint\_Error is propagated. If Target\_Parent equals Source\_Parent there is no effect. If Source\_Parent is an ancestor of Target\_Parent other than Target\_Parent itself, then Constraint\_Error is propagated. Otherwise, the child elements (and the further descendants) of Source\_Parent are moved to be child elements of Target\_Parent. If Target\_Parent already has 191/3

child elements, then the moved elements are inserted prior to the node designated by Before, or, if Before equals No\_Element, the moved elements are inserted after the last existing child node of Target\_Parent. The parent of each moved child element is set to Target\_Parent.

- 192/3    **function** Parent (Position : Cursor) **return** Cursor;
- 193/3    {AI05-0136-1} If Position is equal to No\_Element or designates a root node, No\_Element is returned. Otherwise, a cursor designating the parent node of the node designated by Position is returned.
- 194/3    **function** First\_Child (Parent : Cursor) **return** Cursor;
- 195/3    {AI05-0136-1} If Parent is equal to No\_Element, then Constraint\_Error is propagated. Otherwise, First\_Child returns a cursor designating the first child node of the node designated by Parent; if there is no such node, No\_Element is returned.
- 196/3    **function** First\_Child\_Element (Parent : Cursor) **return** Element\_Type;
- 197/3    {AI05-0136-1} Equivalent to Element (First\_Child (Parent)).
- 198/3    **function** Last\_Child (Parent : Cursor) **return** Cursor;
- 199/3    {AI05-0136-1} If Parent is equal to No\_Element, then Constraint\_Error is propagated. Otherwise, Last\_Child returns a cursor designating the last child node of the node designated by Parent; if there is no such node, No\_Element is returned.
- 200/3    **function** Last\_Child\_Element (Parent : Cursor) **return** Element\_Type;
- 201/3    {AI05-0136-1} Equivalent to Element (Last\_Child (Parent)).
- 202/3    **function** Next\_Sibling (Position : Cursor) **return** Cursor;
- 203/3    {AI05-0136-1} If Position equals No\_Element or designates the last child node of its parent, then Next\_Sibling returns the value No\_Element. Otherwise, it returns a cursor that designates the successor (with the same parent) of the node designated by Position.
- 204/3    **function** Previous\_Sibling (Position : Cursor) **return** Cursor;
- 205/3    {AI05-0136-1} If Position equals No\_Element or designates the first child node of its parent, then Previous\_Sibling returns the value No\_Element. Otherwise, it returns a cursor that designates the predecessor (with the same parent) of the node designated by Position.
- 206/3    **procedure** Next\_Sibling (Position : **in out** Cursor);

| {AI05-0212-1} {AI05-0265-1} Iterate_Children returns a reversible iterator object (see 5.5.1) that will generate a value for a loop parameter (see 5.5.2) designating each child node of Parent. If Parent equals No_Element, then Constraint_Error is propagated. If Parent does not designate a node in Container, then Program_Error is propagated. Otherwise, when used as a forward iterator, the nodes are designated starting with the first child node and moving the cursor as per the function Next_Sibling; when used as a reverse iterator, the nodes are designated starting with the last child node and moving the cursor as per the function Previous_Sibling. Tampering with the cursors of Container is prohibited while the iterator object exists (in particular, in the sequence_of_statements of the loop_statement whose iterator_specification denotes this object). The iterator object needs finalization. | 219/3 |

*Bounded (Run-Time) Errors*

|                                                                                                                                                                                                                                                                                                                                                                                                                         |       |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|
| {AI05-0136-1} {AI05-0248-1} It is a bounded error for the actual function associated with a generic formal subprogram, when called as part of an operation of this package, to tamper with elements of any Tree parameter of the operation. Either Program_Error is raised, or the operation works as defined on the value of the Tree either prior to, or subsequent to, some or all of the modifications to the Tree. | 220/3 |
| {AI05-0136-1} It is a bounded error to call any subprogram declared in the visible part of Containers.Multiway_Trees when the associated container has been finalized. If the operation takes Container as an <b>in out</b> parameter, then it raises Constraint_Error or Program_Error. Otherwise, the operation either proceeds as it would for an empty container, or it raises Constraint_Error or Program_Error.   | 221/3 |

*Erroneous Execution*

|                                                                                                                                                                                                                                                                                                                                                                          |         |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| {AI05-0136-1} A Cursor value is <i>invalid</i> if any of the following have occurred since it was created:                                                                                                                                                                                                                                                               | 222/3   |
| <ul style="list-style-type: none"> <li>• The tree that contains the element it designates has been finalized;</li> </ul>                                                                                                                                                                                                                                                 | 223/3   |
| <ul style="list-style-type: none"> <li>• The tree that contains the element it designates has been used as the Source or Target of a call to Move;</li> </ul>                                                                                                                                                                                                            | 224/3   |
| <ul style="list-style-type: none"> <li>• The tree that contains the element it designates has been used as the Target of a call to Assign or the target of an assignment_statement;</li> </ul>                                                                                                                                                                           | 225/3   |
| <ul style="list-style-type: none"> <li>• The element it designates has been removed from the tree that previously contained the element.</li> </ul>                                                                                                                                                                                                                      | 226/3   |
| <b>Reason:</b> We talk about which tree the element was removed from in order to handle splicing nodes from one tree to another. The node still exists, but any cursors that designate it in the original tree are now invalid. This bullet covers removals caused by calls to Clear, Delete_Leaf, Delete_Subtree, Delete_Children, Splice_Children, and Splice_Subtree. | 226.a/3 |

227/3 The result of "=" or Has\_Element is unspecified if it is called with an invalid cursor parameter. Execution is erroneous if any other subprogram declared in Containers.Multiway\_Trees is called with an invalid cursor parameter.

227.a/3 **Discussion:** The list above is intended to be exhaustive. In other cases, a cursor value continues to designate its original element (or the root node). For instance, cursor values survive the insertion and deletion of other nodes.

227.b/3 While it is possible to check for these cases, in many cases the overhead necessary to make the check is substantial in time or space. Implementations are encouraged to check for as many of these cases as possible and raise Program\_Error if detected.

228/3 {AI05-0212-1} Execution is erroneous if the tree associated with the result of a call to Reference or Constant\_Reference is finalized before the result object returned by the call to Reference or Constant\_Reference is finalized.

228.a/3 **Reason:** Each object of Reference\_Type and Constant\_Reference\_Type probably contains some reference to the originating container. If that container is prematurely finalized (which is only possible via Unchecked\_Deallocation, as accessibility checks prevent passing a container to Reference that will not live as long as the result), the finalization of the object of Reference\_Type will try to access a nonexistent object. This is a normal case of a dangling pointer created by Unchecked\_Deallocation; we have to explicitly mention it here as the pointer in question is not visible in the specification of the type. (This is the same reason we have to say this for invalid cursors.)

*Implementation Requirements*

229/3 {AI05-0136-1} No storage associated with a multiway tree object shall be lost upon assignment or scope exit.

230/3 {AI05-0136-1} {AI05-0262-1} The execution of an assignment\_statement for a tree shall have the effect of copying the elements from the source tree object to the target tree object and changing the node count of the target object to that of the source object.

230.a/3 **Implementation Note:** {AI05-0298-1} An assignment of a Tree is a “deep” copy; that is the elements are copied as well the data structures. We say “effect of” in order to allow the implementation to avoid copying elements immediately if it wishes. For instance, an implementation that avoided copying until one of the containers is modified would be allowed. (Note that this implementation would require care, see A.18.2 for more.)

*Implementation Advice*

231/3 {AI05-0136-1} Containers.Multiway\_Trees should be implemented similarly to a multiway tree. In particular, if  $N$  is the overall number of nodes for a particular tree, then the worst-case time complexity of Element, Parent, First\_Child, Last\_Child, Next\_Sibling, Previous\_Sibling, Insert\_Child with Count=1, and Delete should be  $O(\log N)$ .

231.a/3 **Implementation Advice:** The worst-case time complexity of the Element, Parent, First\_Child, Last\_Child, Next\_Sibling, Previous\_Sibling, Insert\_Child with Count=1, and Delete operations of Containers.Multiway\_Trees should be  $O(\log N)$ .

231.b/3 **Reason:** We do not mean to overly constrain implementation strategies here. However, it is important for portability that the performance of large containers has roughly the same factors on different implementations. If a program is moved to an implementation that takes  $O(N)$  time to access elements, that program could be unusable when the trees are large. We allow  $O(\log N)$  access because the proportionality constant and caching effects are likely to be larger than the log factor, and we don't want to discourage innovative implementations.

232/3 {AI05-0136-1} Move should not copy elements, and should minimize copying of internal data structures.

232.a/3 **Implementation Advice:** Containers.Multiway\_Trees.Move should not copy elements, and should minimize copying of internal data structures.

232.b/3 **Implementation Note:** Usually that can be accomplished simply by moving the pointer(s) to the internal data structures from the Source container to the Target container.

233/3 {AI05-0136-1} If an exception is propagated from a tree operation, no storage should be lost, nor any elements removed from a tree unless specified by the operation.

233.a/3 **Implementation Advice:** If an exception is propagated from a tree operation, no storage should be lost, nor any elements removed from a tree unless specified by the operation.

**Reason:** This is important so that programs can recover from errors. But we don't want to require heroic efforts, so we just require documentation of cases where this can't be accomplished. 233.b/3

*Extensions to Ada 2005*

{AI05-0136-1} {AI05-0257-1} {AI05-0265-1} {AI05-0269-1} The generic package Containers.Multiway\_Trees is new. 233.c/3

## A.18.11 The Generic Package Containers.Indefinite\_Vectors

{AI95-00302-03} The language-defined generic package Containers.Indefinite\_Vectors provides a private type Vector and a set of operations. It provides the same operations as the package Containers.Vectors (see A.18.2), with the difference that the generic formal Element\_Type is indefinite. 1/2

*Static Semantics*

{AI95-00302-03} {AI05-0092-1} The declaration of the generic library package Containers.Indefinite\_Vectors has the same contents and semantics as Containers.Vectors except: 2/3

- The generic formal Element\_Type is indefinite. 3/2

- The procedures with the profiles: 4/2

```
procedure Insert (Container : in out Vector;
 Before : in Extended_Index;
 Count : in Count_Type := 1); 5/2
```

```
procedure Insert (Container : in out Vector;
 Before : in Cursor;
 Position : in out Cursor;
 Count : in Count_Type := 1); 6/2
```

are omitted. 7/2

**Discussion:** These procedures are omitted because there is no way to create a default-initialized object of an indefinite type. Note that Insert\_Space can be used instead of this routine in most cases. Omitting the routine completely allows any problems to be diagnosed by the compiler when converting from a definite to indefinite vector. 7.a/2

- The actual Element parameter of access subprogram Process of Update\_Element may be constrained even if Element\_Type is unconstrained. 8/2

*Extensions to Ada 95*

{AI95-00302-03} The generic package Containers.Indefinite\_Vectors is new. 8.a/2

## A.18.12 The Generic Package Containers.Indefinite\_Doubly\_Linked\_Lists

{AI95-00302-03} The language-defined generic package Containers.Indefinite\_Doubly\_Linked\_Lists provides private types List and Cursor, and a set of operations for each type. It provides the same operations as the package Containers.Doubly\_Linked\_Lists (see A.18.3), with the difference that the generic formal Element\_Type is indefinite. 1/2

*Static Semantics*

{AI95-00302-03} {AI05-0092-1} The declaration of the generic library package Containers.Indefinite\_Doubly\_Linked\_Lists has the same contents and semantics as Containers.Doubly\_Linked\_Lists except: 2/3

- The generic formal Element\_Type is indefinite. 3/2

4/2 • The procedure with the profile:  
 5/2 `procedure Insert (Container : in out List;  
                   Before      : in      Cursor;  
                   Position   :      out Cursor;  
                   Count      : in      Count_Type := 1);`

6/2 is omitted.

6.a/2 **Discussion:** This procedure is omitted because there is no way to create a default-initialized object of an indefinite type. We considered having this routine insert an empty element similar to the empty elements of a vector, but rejected this possibility because the semantics are fairly complex and very different from the existing definite container. That would make it more error-prone to convert a container from a definite type to an indefinite type; by omitting the routine completely, any problems will be diagnosed by the compiler.

7/2 • The actual Element parameter of access subprogram Process of Update\_Element may be constrained even if Element\_Type is unconstrained.

*Extensions to Ada 95*

7.a/2 {AI95-00302-03} The generic package Containers.Indefinite\_Doubly\_Linked\_Lists is new.

### A.18.13 The Generic Package Containers.Indefinite\_Hashed\_Maps

1/2 {AI95-00302-03} The language-defined generic package Containers.Indefinite\_Hashed\_Maps provides a map with the same operations as the package Containers.Hashed\_Maps (see A.18.5), with the difference that the generic formal types Key\_Type and Element\_Type are indefinite.

*Static Semantics*

2/3 {AI95-00302-03} {AI05-0092-1} The declaration of the generic library package Containers.Indefinite\_Hashed\_Maps has the same contents and semantics as Containers.Hashed\_Maps except:

- 3/2 • The generic formal Key\_Type is indefinite.
- 4/2 • The generic formal Element\_Type is indefinite.
- 5/2 • The procedure with the profile:

6/2 `procedure Insert (Container : in out Map;  
                   Key       : in      Key_Type;  
                   Position  :      out Cursor;  
                   Inserted  :      out Boolean);`

7/2 is omitted.

7.a/2 **Discussion:** This procedure is omitted because there is no way to create a default-initialized object of an indefinite type. We considered having this routine insert an empty element similar to the empty elements of a vector, but rejected this possibility because the semantics are fairly complex and very different from the existing case. That would make it more error-prone to convert a container from a definite type to an indefinite type; by omitting the routine completely, any problems will be diagnosed by the compiler.

8/2 • The actual Element parameter of access subprogram Process of Update\_Element may be constrained even if Element\_Type is unconstrained.

*Extensions to Ada 95*

8.a/2 {AI95-00302-03} The generic package Containers.Indefinite\_Hashed\_Maps is new.

### A.18.14 The Generic Package Containers.Indefinite\_Ordered\_Maps

1/2 {AI95-00302-03} The language-defined generic package Containers.Indefinite\_Ordered\_Maps provides a map with the same operations as the package Containers.Ordered\_Maps (see A.18.6), with the difference that the generic formal types Key\_Type and Element\_Type are indefinite.

*Static Semantics*

{AI95-00302-03} {AI05-0092-1} The declaration of the generic library package Containers.Indefinite\_Ordered\_Maps has the same contents and semantics as Containers.Ordered\_Maps except:

- The generic formal Key\_Type is indefinite. 3/2
- The generic formal Element\_Type is indefinite. 4/2
- The procedure with the profile: 5/2

```

procedure Insert (Container : in out Map;
 Key : in Key_Type;
 Position : out Cursor;
 Inserted : out Boolean);

```

is omitted. 7/2

**Discussion:** This procedure is omitted because there is no way to create a default-initialized object of an indefinite type. We considered having this routine insert an empty element similar to the empty elements of a vector, but rejected this possibility because the semantics are fairly complex and very different from the existing case. That would make it more error-prone to convert a container from a definite type to an indefinite type; by omitting the routine completely, any problems will be diagnosed by the compiler. 7.a/2

- The actual Element parameter of access subprogram Process of Update\_Element may be constrained even if Element\_Type is unconstrained. 8/2

*Extensions to Ada 95*

{AI95-00302-03} The generic package Containers.Indefinite\_Ordered\_Maps is new. 8.a/2

## A.18.15 The Generic Package Containers.Indefinite\_Hashed\_Sets

{AI95-00302-03} The language-defined generic package Containers.Indefinite\_Hashed\_Sets provides a set with the same operations as the package Containers.Hashed\_Sets (see A.18.8), with the difference that the generic formal type Element\_Type is indefinite. 1/2

*Static Semantics*

{AI95-00302-03} {AI05-0092-1} The declaration of the generic library package Containers.Indefinite\_Hashed\_Sets has the same contents and semantics as Containers.Hashed\_Sets except:

- The generic formal Element\_Type is indefinite. 3/2
- The actual Element parameter of access subprogram Process of Update\_Element\_Preserving\_Key may be constrained even if Element\_Type is unconstrained. 4/2

*Extensions to Ada 95*

{AI95-00302-03} The generic package Containers.Indefinite\_Hashed\_Sets is new. 4.a/2

## A.18.16 The Generic Package Containers.Indefinite\_Ordered\_Sets

{AI95-00302-03} The language-defined generic package Containers.Indefinite\_Ordered\_Sets provides a set with the same operations as the package Containers.Ordered\_Sets (see A.18.9), with the difference that the generic formal type Element\_Type is indefinite. 1/2

*Static Semantics*

2/3 {AI95-00302-03} {AI05-0092-1} The declaration of the generic library package Containers.Indefinite\_Ordered\_Sets has the same contents and semantics as Containers.Ordered\_Sets except:

- 3/2 • The generic formal Element\_Type is indefinite.
- 4/2 • The actual Element parameter of access subprogram Process of Update\_Element\_Preserving\_Key may be constrained even if Element\_Type is unconstrained.

*Extensions to Ada 95*

4.a/2 {AI95-00302-03} The generic package Containers.Indefinite\_Ordered\_Sets is new.

**A.18.17 The Generic Package Containers.Indefinite\_Multiway\_Trees**

1/3 {AI05-0136-1} The language-defined generic package Containers.Indefinite\_Multiway\_Trees provides a multiway tree with the same operations as the package Containers.Multiway\_Trees (see A.18.10), with the difference that the generic formal Element\_Type is indefinite.

*Static Semantics*

2/3 {AI05-0136-1} The declaration of the generic library package Containers.Indefinite\_Multiway\_Trees has the same contents and semantics as Containers.Multiway\_Trees except:

- 3/3 • The generic formal Element\_Type is indefinite.
- 4/3 • The procedure with the profile:

```
5/3 procedure Insert_Child (Container : in out Tree;
 Parent : in Cursor;
 Before : in Cursor;
 Position : out Cursor;
 Count : in Count_Type := 1);
```

6/3 is omitted.

6.a/3 **Discussion:** This procedure is omitted because there is no way to create a default-initialized object of an indefinite type. We considered having this routine insert an empty element similar to the empty elements of a vector, but rejected this possibility because the semantics are fairly complex and very different from the existing case. That would make it more error-prone to convert a container from a definite type to an indefinite type; by omitting the routine completely, any problems will be diagnosed by the compiler.

- 7/3 • The actual Element parameter of access subprogram Process of Update\_Element may be constrained even if Element\_Type is unconstrained.

*Extensions to Ada 2005*

7.a/3 {AI05-0136-1} The generic package Containers.Indefinite\_Multiway\_Trees is new.

**A.18.18 The Generic Package Containers.Indefinite\_Holders**

1/3 {AI05-0069-1} The language-defined generic package Containers.Indefinite\_Holders provides a private type Holder and a set of operations for that type. A holder container holds a single element of an indefinite type.

2/3 {AI05-0069-1} A holder container allows the declaration of an object that can be used like an uninitialized variable or component of an indefinite type.

3/3 {AI05-0069-1} A holder container may be *empty*. An empty holder does not contain an element.

## Static Semantics

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |        |

| <i>{AI05-0069-1}</i> | The actual function for the generic formal function "=" on Element_Type values is expected to define a reflexive and symmetric relationship and return the same result value each time it is called with a particular pair of values. If it behaves in some other manner, the function "=" on holder values returns an unspecified value. The exact arguments and number of calls of this generic formal function by the function "=" on holder values are unspecified.                             | 26/3   |
|                      | <b>Ramification:</b> If the actual function for "=" is not symmetric and consistent, the result returned by any of the functions defined to use "=" cannot be predicted. The implementation is not required to protect against "=" raising an exception, or returning random results, or any other "bad" behavior. And it can call "=" in whatever manner makes sense. But note that only the results of the function "=" is unspecified; other subprograms are not allowed to break if "=" is bad. | 26.a/3 |
| <i>{AI05-0069-1}</i> | The type Holder is used to represent holder containers. The type Holder needs finalization (see 7.6).                                                                                                                                                                                                                                                                                                                                                                                               | 27/3   |

- 28/3 {AI05-0069-1} Empty\_Holder represents an empty holder object. If an object of type Holder is not otherwise initialized, it is initialized to the same value as Empty\_Holder.
- 29/3 {AI05-0069-1} {AI05-0262-1} [Some operations of this generic package have access-to-subprogram parameters. To ensure such operations are well-defined, they guard against certain actions by the designated subprogram. In particular, some operations check for “tampering with the element” of a container because they depend on the element of the container not being replaced.]
- 30/3 {AI05-0069-1} {AI05-0262-1} A subprogram is said to *tamper with the element* of a holder object *H* if:
- 31/3 • It clears the element contained by *H*, that is, it calls the Clear procedure with *H* as a parameter;
  - 32/3 • It replaces the element contained by *H*, that is, it calls the Replace\_Element procedure with *H* as a parameter;
  - 33/3 • It calls the Move procedure with *H* as a parameter;
  - 34/3 • It finalizes *H*.
- 34.a/3 **Reason:** Complete replacement of an element can cause its memory to be deallocated while another operation is holding onto a reference to it. That can't be allowed. However, a simple modification of (part of) an element is not a problem, so Update\_Element does not cause a problem.
- 35/3 {AI05-0265-1} When tampering with the element is *prohibited* for a particular holder object *H*, Program\_Error is propagated by a call of any language-defined subprogram that is defined to tamper with the element of *H*, leaving *H* unmodified.
- 36/3 **function** "=" (Left, Right : Holder) **return** Boolean;
- 37/3 {AI05-0069-1} If Left and Right denote the same holder object, then the function returns True. Otherwise, it compares the element contained in Left to the element contained in Right using the generic formal equality operator, returning the result of that operation. Any exception raised during the evaluation of element equality is propagated.
- 37.a/3 **Implementation Note:** This wording describes the canonical semantics. However, the order and number of calls on the formal equality **function** is unspecified, so an implementation need not call the equality function if the correct answer can be determined without doing so.
- 38/3 **function** To\_Holder (New\_Item : Element\_Type) **return** Holder;
- 39/3 {AI05-0069-1} Returns a nonempty holder containing an element initialized to New\_Item.
- 40/3 **function** Is\_Empty (Container : Holder) **return** Boolean;
- 41/3 {AI05-0069-1} Returns True if Container is empty, and False if it contains an element.
- 42/3 **procedure** Clear (Container : **in out** Holder);
- 43/3 {AI05-0069-1} Removes the element from Container. Container is empty after a successful Clear operation.
- 44/3 **function** Element (Container : Holder) **return** Element\_Type;
- 45/3 {AI05-0069-1} If Container is empty, Constraint\_Error is propagated. Otherwise, returns the element stored in Container.
- 46/3 **procedure** Replace\_Element (Container : **in out** Holder;  
New\_Item : **in** Element\_Type);
- 47/3 {AI05-0069-1} Replace\_Element assigns the value New\_Item into Container, replacing any preexisting content of Container. Container is not empty after a successful call to Replace\_Element.

Tampering with the elements of Container is prohibited while the object returned by Constant_Reference exists and has not been finalized.                                           | 58/3   |
| {AI05-0212-1} <b>function</b> Reference (Container : <b>aliased in out</b> Holder)<br><b>return</b> Reference_Type;                                                                                                                                                                                                                                                                                               | 59/3   |
| {AI05-0212-1} This function (combined with the Implicit_Dereference aspects) provides a convenient way to gain read and write access to the contained element of a holder container.                                                                                                                                                                                                                              | 60/3   |
| {AI05-0212-1} {AI05-0262-1} {AI05-0265-1} If Container is empty, Constraint_Error is propagated. Otherwise, Reference returns an object whose discriminant is an access value that designates the contained element. Tampering with the elements of Container is prohibited while the object returned by Reference exists and has not been finalized.                                                             | 61/3   |

- 62/3     **procedure** Assign (Target : **in out** Holder; Source : **in** Holder);
- 63/3     {AI05-0001-1} If Target denotes the same object as Source, the operation has no effect. If Source is empty, Clear (Target) is called. Otherwise, Replace\_Element (Target, Element (Source)) is called.
- 63.a/3     **Discussion:** {AI05-0005-1} This routine exists for compatibility with the other containers. For a holder, Assign (A, B) and A := B behave effectively the same. (Assign Clears the Target, while := finalizes the Target, but these should have similar effects.)
- 64/3     **function** Copy (Source : Holder) **return** Holder;
- 65/3     {AI05-0001-1} If Source is empty, returns an empty holder container; otherwise, returns To\_Holder (Element (Source)).
- 66/3     **procedure** Move (Target : **in out** Holder; Source : **in out** Holder);
- 67/3     {AI05-0069-1} {AI05-0248-1} If Target denotes the same object as Source, then the operation has no effect. Otherwise, the element contained by Source (if any) is removed from Source and inserted into Target, replacing any preexisting content. Source is empty after a successful call to Move.

*Bounded (Run-Time) Errors*

- 68/3     {AI05-0022-1} {AI05-0069-1} {AI05-0248-1} {AI05-0262-1} It is a bounded error for the actual function associated with a generic formal subprogram, when called as part of an operation of this package, to tamper with the element of any Holder parameter of the operation. Either Program\_Error is raised, or the operation works as defined on the value of the Holder either prior to, or subsequent to, some or all of the modifications to the Holder.
- 69/3     {AI05-0027-1} {AI05-0069-1} It is a bounded error to call any subprogram declared in the visible part of Containers.Indefinite\_Holders when the associated container has been finalized. If the operation takes Container as an **in out** parameter, then it raises Constraint\_Error or Program\_Error. Otherwise, the operation either proceeds as it would for an empty container, or it raises Constraint\_Error or Program\_Error.

*Erroneous Execution*

- 70/3     {AI05-0212-1} {AI05-0269-1} Execution is erroneous if the holder container associated with the result of a call to Reference or Constant\_Reference is finalized before the result object returned by the call to Reference or Constant\_Reference is finalized.
- 70.a/3     **Reason:** {AI05-0212-1} Each object of Reference\_Type and Constant\_Reference\_Type probably contains some reference to the originating container. If that container is prematurely finalized (which is only possible via Unchecked\_Deallocation, as accessibility checks prevent passing a container to Reference that will not live as long as the result), the finalization of the object of Reference\_Type will try to access a nonexistent object. This is a normal case of a dangling pointer created by Unchecked\_Deallocation; we have to explicitly mention it here as the pointer in question is not visible in the specification of the type. (This is the same reason we have to say this for invalid cursors.)

*Implementation Requirements*

- 71/3     {AI05-0069-1} No storage associated with a holder object shall be lost upon assignment or scope exit.
- 72/3     {AI05-0069-1} {AI05-0269-1} The execution of an **assignment\_statement** for a holder container shall have the effect of copying the element (if any) from the source holder object to the target holder object.
- 72.a/3     **Implementation Note:** {AI05-0298-1} An assignment of a holder container is a “deep” copy; that is the element is copied as well as any data structures. We say “effect of” in order to allow the implementation to avoid copying the element immediately if it wishes. For instance, an implementation that avoided copying until one of the containers is modified would be allowed. (Note that this implementation would require care, see A.18.2 for more.)

*Implementation Advice*

- {AI05-0069-1} {AI05-0269-1} Move should not copy the element, and should minimize copying of internal data structures. 73/3
- Implementation Advice:** Containers.Indefinite\_Holders.Move should not copy the element, and should minimize copying of internal data structures. 73.a.1/3
- Implementation Note:** Usually that can be accomplished simply by moving the pointer(s) to the internal data structures from the Source holder to the Target holder. 73.a/3
- {AI05-0069-1} {AI05-0269-1} If an exception is propagated from a holder operation, no storage should be lost, nor should the element be removed from a holder container unless specified by the operation. 74/3
- Implementation Advice:** If an exception is propagated from a holder operation, no storage should be lost, nor should the element be removed from a holder container unless specified by the operation. 74.a.1/3
- Reason:** This is important so that programs can recover from errors. But we don't want to require heroic efforts, so we just require documentation of cases where this can't be accomplished. 74.a/3
- Extensions to Ada 2005*
- {AI05-0069-1} {AI05-0084-1} {AI05-0265-1} The generic package Containers.Indefinite\_Holders is new. 74.b/3

**A.18.19 The Generic Package Containers.Bounded\_Vectors**

{AI05-0001-1} The language-defined generic package Containers.Bounded\_Vectors provides a private type Vector and a set of operations. It provides the same operations as the package Containers.Vectors (see A.18.2), with the difference that the maximum storage is bounded. 1/3

*Static Semantics*

- {AI05-0001-1} The declaration of the generic library package Containers.Bounded\_Vectors has the same contents and semantics as Containers.Vectors except: 2/3
- The pragma Preelaborate is replaced with pragma Pure. 3/3
  - The type Vector is declared with a discriminant that specifies the capacity: 4/3  
`type Vector (Capacity : Count_Type) is tagged private;` 5/3
  - The type Vector needs finalization if and only if type Element\_Type needs finalization. 6/3  
**Implementation Note:** {AI05-0212-1} The type Vector cannot depend on package Ada.Finalization unless the element type depends on that package. The objects returned from the Iterator and Reference functions probably do depend on package Ada.Finalization. Restricted environments may need to avoid use of those functions and their associated types. 6.a/3
  - In function Copy, if the Capacity parameter is equal to or greater than the length of Source, the vector capacity exactly equals the value of the Capacity parameter. 7/3
  - The description of Reserve\_Capacity is replaced with: 8/3  
 If the specified Capacity is larger than the capacity of Container, then Reserve\_Capacity propagates Capacity\_Error. Otherwise, the operation has no effect. 9/3

*Bounded (Run-Time) Errors*

- {AI05-0160-1} {AI05-0265-1} It is a bounded error to assign from a bounded vector object while tampering with elements [or cursors] of that object is prohibited. Either Program\_Error is raised by the assignment, execution proceeds with the target object prohibiting tampering with elements [or cursors], or execution proceeds normally. 10/3
- Proof:** Tampering with elements includes tampering with cursors, so we only really need to talk about tampering with elements here; we mention cursors for clarity. 10.a/3

*Erroneous Execution*

11/3 {AI05-0265-1} When a bounded vector object *V* is finalized, if tampering with cursors is prohibited for *V* other than due to an assignment from another vector, then execution is erroneous.

11.a/3 **Reason:** This is a tampering event, but since the implementation is not allowed to use `Ada.Finalization`, it is not possible in a pure Ada implementation to detect this error. (There is no `Finalize` routine that will be called that could make the check.) Since the check probably cannot be made, the bad effects that could occur (such as an iterator going into an infinite loop or accessing a nonexistent element) cannot be prevented and we have to allow anything. We do allow re-assigning an object that only prohibits tampering because it was copied from another object as that cannot cause any negative effects.

*Implementation Requirements*

12/3 {AI05-0184-1} {AI05-0264-1} For each instance of `Containers.Vectors` and each instance of `Containers.Bounded_Vectors`, if the two instances meet the following conditions, then the output generated by the `Vector'Output` or `Vector'Write` subprograms of either instance shall be readable by the `Vector'Input` or `Vector'Read` of the other instance, respectively:

- 13/3 • {AI05-0184-1} {AI05-0248-1} the `Element_Type` parameters of the two instances are statically matching subtypes of the same type; and
- 14/3 • {AI05-0184-1} the output generated by `Element_Type'Output` or `Element_Type'Write` is readable by `Element_Type'Input` or `Element_Type'Read`, respectively (where `Element_Type` denotes the type of the two actual `Element_Type` parameters); and
- 15/3 • {AI05-0184-1} the preceding two conditions also hold for the `Index_Type` parameters of the instances.

*Implementation Advice*

16/3 {AI05-0001-1} Bounded vector objects should be implemented without implicit pointers or dynamic allocation.

16.a.1/3 **Implementation Advice:** Bounded vector objects should be implemented without implicit pointers or dynamic allocation.

17/3 {AI05-0001-1} The implementation advice for procedure `Move` to minimize copying does not apply.

17.a.1/3 **Implementation Advice:** The implementation advice for procedure `Move` to minimize copying does not apply to bounded vectors.

*Extensions to Ada 2005*

17.a/3 {AI05-0001-1} {AI05-0160-1} {AI05-0184-1} The generic package `Containers.Bounded_Vectors` is new.

## A.18.20 The Generic Package `Containers.Bounded_Doubly_Linked_Lists`

1/3 {AI05-0001-1} The language-defined generic package `Containers.Bounded_Doubly_Linked_Lists` provides a private type `List` and a set of operations. It provides the same operations as the package `Containers.Doubly_Linked_Lists` (see A.18.3), with the difference that the maximum storage is bounded.

*Static Semantics*

2/3 {AI05-0001-1} The declaration of the generic library package `Containers.Bounded_Doubly_Linked_Lists` has the same contents and semantics as `Containers.Doubly_Linked_Lists` except:

- 3/3 • The pragma `Preelaborate` is replaced with pragma `Pure`.
- 4/3 • The type `List` is declared with a discriminant that specifies the capacity (maximum number of elements) as follows:

- `type List (Capacity : Count_Type) is tagged private;` 5/3
- The type List needs finalization if and only if type Element\_Type needs finalization. 6/3
    - Implementation Note:** {AI05-0212-1} The type List cannot depend on package Ada.Finalization unless the element type depends on that package. The objects returned from the Iterator and Reference functions probably do depend on package Ada.Finalization. Restricted environments may need to avoid use of those functions and their associated types. 6.a/3
  - The allocation of internal storage includes a check that the capacity is not exceeded, and Capacity\_Error is raised if this check fails. 7/3
  - In procedure Assign, if Source length is greater than Target capacity, then Capacity\_Error is propagated. 8/3
  - The function Copy is replaced with: 9/3
 

```
function Copy (Source : List; Capacity : Count_Type := 0)
 return List;
```

 10/3
 

If Capacity is 0, then the list capacity is the length of Source; if Capacity is equal to or greater than the length of Source, the list capacity equals the value of the Capacity parameter; otherwise, the operation propagates Capacity\_Error. 11/3
  - In the three-parameter procedure Splice whose Source has type List, if the sum of the length of Target and the length of Source is greater than the capacity of Target, then Splice propagates Capacity\_Error. 12/3
  - In the four-parameter procedure Splice, if the length of Target equals the capacity of Target, then Splice propagates Capacity\_Error. 13/3

*Bounded (Run-Time) Errors*

{AI05-0160-1} {AI05-0265-1} It is a bounded error to assign from a bounded list object while tampering with elements [or cursors] of that object is prohibited. Either Program\_Error is raised by the assignment, execution proceeds with the target object prohibiting tampering with elements [or cursors], or execution proceeds normally. 14/3

**Proof:** Tampering with elements includes tampering with cursors, so we only really need to talk about tampering with elements here; we mention cursors for clarity. 14.a/3

*Erroneous Execution*

{AI05-0265-1} When a bounded list object *L* is finalized, if tampering with cursors is prohibited for *L* other than due to an assignment from another list, then execution is erroneous. 15/3

**Reason:** This is a tampering event, but since the implementation is not allowed to use Ada.Finalization, it is not possible in a pure Ada implementation to detect this error. (There is no Finalize routine that will be called that could make the check.) Since the check probably cannot be made, the bad effects that could occur (such as an iterator going into an infinite loop or accessing a nonexistent element) cannot be prevented and we have to allow anything. We do allow re-assigning an object that only prohibits tampering because it was copied from another object as that cannot cause any negative effects. 15.a/3

*Implementation Requirements*

{AI05-0184-1} {AI05-0264-1} For each instance of Containers.Doubly\_Linked\_Lists and each instance of Containers.Bounded\_Doubly\_Linked\_Lists, if the two instances meet the following conditions, then the output generated by the List'Output or List'Write subprograms of either instance shall be readable by the List'Input or List'Read of the other instance, respectively: 16/3

- {AI05-0184-1} {AI05-0248-1} the Element\_Type parameters of the two instances are statically matching subtypes of the same type; and 17/3
- {AI05-0184-1} the output generated by Element\_Type'Output or Element\_Type'Write is readable by Element\_Type'Input or Element\_Type'Read, respectively (where Element\_Type denotes the type of the two actual Element\_Type parameters). 18/3

*Implementation Advice*

- 19/3 {AI05-0001-1} Bounded list objects should be implemented without implicit pointers or dynamic allocation.
- 19.a.1/3 **Implementation Advice:** Bounded list objects should be implemented without implicit pointers or dynamic allocation.
- 20/3 {AI05-0001-1} The implementation advice for procedure Move to minimize copying does not apply.
- 20.a.1/3 **Implementation Advice:** The implementation advice for procedure Move to minimize copying does not apply to bounded lists.

*Extensions to Ada 2005*

- 20.a/3 {AI05-0001-1} {AI05-0160-1} {AI05-0184-1} The generic package Containers.Bounded\_Doubly\_Linked\_Lists is new.

**A.18.21 The Generic Package Containers.Bounded\_Hashed\_Maps**

- 1/3 {AI05-0001-1} The language-defined generic package Containers.Bounded\_Hashed\_Maps provides a private type Map and a set of operations. It provides the same operations as the package Containers.Hashed\_Maps (see A.18.5), with the difference that the maximum storage is bounded.

*Static Semantics*

- 2/3 {AI05-0001-1} The declaration of the generic library package Containers.Bounded\_Hashed\_Maps has the same contents and semantics as Containers.Hashed\_Maps except:
- 3/3
- The pragma Preelaborate is replaced with pragma Pure.
- 4/3
- The type Map is declared with discriminants that specify both the capacity (number of elements) and modulus (number of distinct hash values) of the hash table as follows:
- 5/3
- ```
type Map (Capacity : Count_Type;
          Modulus   : Hash_Type) is tagged private;
```
- 6/3
- The type Map needs finalization if and only if type Key_Type or type Element_Type needs finalization.
- 6.a/3
- Implementation Note:** {AI05-0212-1} The type Map cannot depend on package Ada.Finalization unless the element or key type depends on that package. The objects returned from the Iterator and Reference functions probably do depend on package Ada.Finalization. Restricted environments may need to avoid use of those functions and their associated types.
- 7/3
- The description of Reserve_Capacity is replaced with:
- 8/3
- If the specified Capacity is larger than the capacity of Container, then Reserve_Capacity propagates Capacity_Error. Otherwise, the operation has no effect.
- 9/3
- An additional operation is added immediately following Reserve_Capacity:
- 10/3
- ```
function Default_Modulus (Capacity : Count_Type) return Hash_Type;
```
- 11/3
- Default\_Modulus returns an implementation-defined value for the number of distinct hash values to be used for the given capacity (maximum number of elements).
- 12/3
- The function Copy is replaced with:
- 13/3
- ```
function Copy (Source   : Map;
              Capacity : Count_Type := 0;
              Modulus   : Hash_Type := 0) return Map;
```
- 14/3
- {AI05-0264-1} Returns a map with key/element pairs initialized from the values in Source. If Capacity is 0, then the map capacity is the length of Source; if Capacity is equal to or greater than the length of Source, the map capacity is the value of the Capacity parameter; otherwise, the operation propagates Capacity_Error. If the Modulus argument is 0, then the map modulus is the

value returned by a call to `Default_Modulus` with the map capacity as its argument; otherwise, the map modulus is the value of the `Modulus` parameter.

Bounded (Run-Time) Errors

{AI05-0160-1} {AI05-0265-1} It is a bounded error to assign from a bounded map object while tampering with elements [or cursors] of that object is prohibited. Either `Program_Error` is raised by the assignment, execution proceeds with the target object prohibiting tampering with elements [or cursors], or execution proceeds normally. 15/3

Proof: Tampering with elements includes tampering with cursors, so we only really need to talk about tampering with elements here; we mention cursors for clarity. 15.a/3

Erroneous Execution

{AI05-0265-1} When a bounded map object *M* is finalized, if tampering with cursors is prohibited for *M* other than due to an assignment from another map, then execution is erroneous. 16/3

Reason: This is a tampering event, but since the implementation is not allowed to use `Ada.Finalization`, it is not possible in a pure Ada implementation to detect this error. (There is no `Finalize` routine that will be called that could make the check.) Since the check probably cannot be made, the bad effects that could occur (such as an iterator going into an infinite loop or accessing a nonexistent element) cannot be prevented and we have to allow anything. We do allow re-assigning an object that only prohibits tampering because it was copied from another object as that cannot cause any negative effects. 16.a/3

Implementation Requirements

{AI05-0184-1} {AI05-0264-1} For each instance of `Containers.Hashed_Maps` and each instance of `Containers.Bounded_Hashed_Maps`, if the two instances meet the following conditions, then the output generated by the `Map'Output` or `Map'Write` subprograms of either instance shall be readable by the `Map'Input` or `Map'Read` of the other instance, respectively: 17/3

- {AI05-0184-1} {AI05-0248-1} the `Element_Type` parameters of the two instances are statically matching subtypes of the same type; and 18/3
- {AI05-0184-1} the output generated by `Element_Type'Output` or `Element_Type'Write` is readable by `Element_Type'Input` or `Element_Type'Read`, respectively (where `Element_Type` denotes the type of the two actual `Element_Type` parameters); and 19/3
- {AI05-0184-1} the preceding two conditions also hold for the `Key_Type` parameters of the instances. 20/3

Implementation Advice

{AI05-0001-1} {AI05-0269-1} Bounded hashed map objects should be implemented without implicit pointers or dynamic allocation. 21/3

Implementation Advice: Bounded hashed map objects should be implemented without implicit pointers or dynamic allocation. 21.a.1/3

{AI05-0001-1} The implementation advice for procedure `Move` to minimize copying does not apply. 22/3

Implementation Advice: The implementation advice for procedure `Move` to minimize copying does not apply to bounded hashed maps. 22.a.1/3

Extensions to Ada 2005

{AI05-0001-1} {AI05-0160-1} {AI05-0184-1} The generic package `Containers.Bounded_Hashed_Maps` is new. 22.a/3

A.18.22 The Generic Package Containers.Bounded_Ordered_Maps

1/3 {AI05-0001-1} The language-defined generic package Containers.Bounded_Ordered_Maps provides a private type Map and a set of operations. It provides the same operations as the package Containers.Ordered_Maps (see A.18.6), with the difference that the maximum storage is bounded.

Static Semantics

2/3 {AI05-0001-1} The declaration of the generic library package Containers.Bounded_Ordered_Maps has the same contents and semantics as Containers.Ordered_Maps except:

- 3/3 • The pragma Preelaborate is replaced with pragma Pure.
- 4/3 • The type Map is declared with a discriminant that specifies the capacity (maximum number of elements) as follows:

5/3 **type** Map (Capacity : Count_Type) **is tagged private**;

- 6/3 • The type Map needs finalization if and only if type Key_Type or type Element_Type needs finalization.

6.a/3 **Implementation Note:** {AI05-0212-1} The type Map cannot depend on package Ada.Finalization unless the element type depends on that package. The objects returned from the Iterator and Reference functions probably do depend on package Ada.Finalization. Restricted environments may need to avoid use of those functions and their associated types.

- 7/3 • The allocation of a new node includes a check that the capacity is not exceeded, and Capacity_Error is raised if this check fails.

- 8/3 • In procedure Assign, if Source length is greater than Target capacity, then Capacity_Error is propagated.

- 9/3 • The function Copy is replaced with:

10/3 **function** Copy (Source : Map;
 Capacity : Count_Type := 0) **return** Map;

11/3 Returns a map with key/element pairs initialized from the values in Source. If Capacity is 0, then the map capacity is the length of Source; if Capacity is equal to or greater than the length of Source, the map capacity is the specified value; otherwise, the operation propagates Capacity_Error.

Bounded (Run-Time) Errors

12/3 {AI05-0160-1} {AI05-0265-1} It is a bounded error to assign from a bounded map object while tampering with elements [or cursors] of that object is prohibited. Either Program_Error is raised by the assignment, execution proceeds with the target object prohibiting tampering with elements [or cursors], or execution proceeds normally.

12.a/3 **Proof:** Tampering with elements includes tampering with cursors, so we only really need to talk about tampering with elements here; we mention cursors for clarity.

Erroneous Execution

13/3 {AI05-0265-1} When a bounded map object *M* is finalized, if tampering with cursors is prohibited for *M* other than due to an assignment from another map, then execution is erroneous.

13.a/3 **Reason:** This is a tampering event, but since the implementation is not allowed to use Ada.Finalization, it is not possible in a pure Ada implementation to detect this error. (There is no Finalize routine that will be called that could make the check.) Since the check probably cannot be made, the bad effects that could occur (such as an iterator going into an infinite loop or accessing a nonexistent element) cannot be prevented and we have to allow anything. We do allow re-assigning an object that only prohibits tampering because it was copied from another object as that cannot cause any negative effects.

Implementation Requirements

{AI05-0184-1} {AI05-0264-1} For each instance of Containers.Ordered_Maps and each instance of Containers.Bounded_Ordered_Maps, if the two instances meet the following conditions, then the output generated by the Map'Output or Map'Write subprograms of either instance shall be readable by the Map'Input or Map'Read of the other instance, respectively: 14/3

- {AI05-0184-1} {AI05-0248-1} the Element_Type parameters of the two instances are statically matching subtypes of the same type; and 15/3
- {AI05-0184-1} the output generated by Element_Type'Output or Element_Type'Write is readable by Element_Type'Input or Element_Type'Read, respectively (where Element_Type denotes the type of the two actual Element_Type parameters); and 16/3
- {AI05-0184-1} the preceding two conditions also hold for the Key_Type parameters of the instances. 17/3

Implementation Advice

A.18.23 The Generic Package Containers.Bounded_Hashed_Sets

{AI05-0001-1} The language-defined generic package Containers.Bounded_Hashed_Sets provides a private type Set and a set of operations. It provides the same operations as the package Containers.Hashed_Sets (see A.18.8), with the difference that the maximum storage is bounded. 1/3

Static Semantics

{AI05-0001-1} The declaration of the generic library package Containers.Bounded_Hashed_Sets has the same contents and semantics as Containers.Hashed_Sets except: 2/3

- The pragma Preelaborate is replaced with pragma Pure. 3/3
- The type Set is declared with discriminants that specify both the capacity (number of elements) and modulus (number of distinct hash values) of the hash table as follows: 4/3

```
type Set (Capacity : Count_Type;
          Modulus   : Hash_Type) is tagged private; 5/3
```

- The type Set needs finalization if and only if type Element_Type needs finalization. 6/3

Implementation Note: {AI05-0212-1} The type Set cannot depend on package Ada.Finalization unless the element or key type depends on that package. The objects returned from the Iterator and Reference functions probably do depend on package Ada.Finalization. Restricted environments may need to avoid use of those functions and their associated types. 6.a/3

- The description of Reserve_Capacity is replaced with: 7/3

If the specified Capacity is larger than the capacity of Container, then Reserve_Capacity propagates Capacity_Error. Otherwise, the operation has no effect. 8/3

- 9/3 • An additional operation is added immediately following Reserve_Capacity:

10/3 `function` Default_Modulus (Capacity : Count_Type) `return` Hash_Type;

11/3 Default_Modulus returns an implementation-defined value for the number of distinct hash values to be used for the given capacity (maximum number of elements).

- 12/3 • The function Copy is replaced with:

13/3 `function` Copy (Source : Set;
Capacity : Count_Type := 0;
Modulus : Hash_Type := 0) `return` Set;

14/3 *{AI05-0264-1}* Returns a set whose elements are initialized from the values in Source. If Capacity is 0, then the set capacity is the length of Source; if Capacity is equal to or greater than the length of Source, the set capacity is the value of the Capacity parameter; otherwise, the operation propagates Capacity_Error. If the Modulus argument is 0, then the set modulus is the value returned by a call to Default_Modulus with the set capacity as its argument; otherwise, the set modulus is the value of the Modulus parameter.

Bounded (Run-Time) Errors

15/3 *{AI05-0160-1}* *{AI05-0265-1}* It is a bounded error to assign from a bounded set object while tampering with elements [or cursors] of that object is prohibited. Either Program_Error is raised by the assignment, execution proceeds with the target object prohibiting tampering with elements [or cursors], or execution proceeds normally.

15.a/3 **Proof:** Tampering with elements includes tampering with cursors, so we only really need to talk about tampering with elements here; we mention cursors for clarity.

Erroneous Execution

16/3 *{AI05-0265-1}* When a bounded set object *S* is finalized, if tampering with cursors is prohibited for *S* other than due to an assignment from another set, then execution is erroneous.

A.18.24 The Generic Package Containers.Bounded_Ordered_Sets

- {AI05-0001-1} The language-defined generic package Containers.Bounded_Ordered_Sets provides a private type Set and a set of operations. It provides the same operations as the package Containers.Ordered_Sets (see A.18.9), with the difference that the maximum storage is bounded. 1/3

Static Semantics

- {AI05-0001-1} The declaration of the generic library package Containers.Bounded_Ordered_Sets has the same contents and semantics as Containers.Ordered_Sets except: 2/3

- The pragma Preelaborate is replaced with pragma Pure. 3/3
- The type Set is declared with a discriminant that specifies the capacity (maximum number of elements) as follows: 4/3

```
type Set (Capacity : Count_Type) is tagged private; 5/3
```

- The type Set needs finalization if and only if type Element_Type needs finalization. 6/3

Implementation Note: {AI05-0212-1} The type Set cannot depend on package Ada.Finalization unless the element type depends on that package. The objects returned from the Iterator and Reference functions probably do depend on package Ada.Finalization. Restricted environments may need to avoid use of those functions and their associated types. 6.a/3

- If Insert (or Include) adds an element, a check is made that the capacity is not exceeded, and Capacity_Error is raised if this check fails. 7/3
- In procedure Assign, if Source length is greater than Target capacity, then Capacity_Error is propagated. 8/3
- The function Copy is replaced with: 9/3

```
function Copy (Source : Set; 10/3
              Capacity : Count_Type := 0) return Set;
```

Returns a set whose elements are initialized from the values in Source. If Capacity is 0, then the set capacity is the length of Source; if Capacity is equal to or greater than the length of Source, the set capacity is the specified value; otherwise, the operation propagates Capacity_Error. 11/3

Bounded (Run-Time) Errors

- {AI05-0160-1} {AI05-0265-1} It is a bounded error to assign from a bounded set object while tampering with elements [or cursors] of that object is prohibited. Either Program_Error is raised by the assignment, execution proceeds with the target object prohibiting tampering with elements [or cursors], or execution proceeds normally. 12/3

Proof: Tampering with elements includes tampering with cursors, so we only really need to talk about tampering with elements here; we mention cursors for clarity. 12.a/3

Erroneous Execution

- {AI05-0265-1} When a bounded set object *S* is finalized, if tampering with cursors is prohibited for *S* other than due to an assignment from another set, then execution is erroneous. 13/3

Reason: This is a tampering event, but since the implementation is not allowed to use Ada.Finalization, it is not possible in a pure Ada implementation to detect this error. (There is no Finalize routine that will be called that could 13.a/3

make the check.) Since the check probably cannot be made, the bad effects that could occur (such as an iterator going into an infinite loop or accessing a nonexistent element) cannot be prevented and we have to allow anything. We do allow re-assigning an object that only prohibits tampering because it was copied from another object as that cannot cause any negative effects.

Implementation Requirements

- 14/3 {AI05-0184-1} {AI05-0264-1} For each instance of Containers.Ordered_Sets and each instance of Containers.Bounded_Ordered_Sets, if the two instances meet the following conditions, then the output generated by the Set'Output or Set'Write subprograms of either instance shall be readable by the Set'Input or Set'Read of the other instance, respectively:
- 15/3 • {AI05-0184-1} {AI05-0248-1} the Element_Type parameters of the two instances are statically matching subtypes of the same type; and
- 16/3 • {AI05-0184-1} the output generated by Element_Type'Output or Element_Type'Write is readable by Element_Type'Input or Element_Type'Read, respectively (where Element_Type denotes the type of the two actual Element_Type parameters).

Implementation Advice

- 17/3 {AI05-0001-1} {AI05-0269-1} Bounded ordered set objects should be implemented without implicit pointers or dynamic allocation.
- 17.a.1/3 **Implementation Advice:** Bounded ordered set objects should be implemented without implicit pointers or dynamic allocation.
- 18/3 {AI05-0001-1} The implementation advice for procedure Move to minimize copying does not apply.
- 18.a.1/3 **Implementation Advice:** The implementation advice for procedure Move to minimize copying does not apply to bounded ordered sets.

Extensions to Ada 2005

- 18.a/3 {AI05-0001-1} {AI05-0160-1} {AI05-0184-1} The generic package Containers.Bounded_Ordered_Sets is new.

A.18.25 The Generic Package Containers.Bounded_Multiway_Trees

- 1/3 {AI05-0136-1} The language-defined generic package Containers.Bounded_Multiway_Trees provides a private type Tree and a set of operations. It provides the same operations as the package Containers.Multiway_Trees (see A.18.10), with the difference that the maximum storage is bounded.

Static Semantics

- 2/3 {AI05-0136-1} The declaration of the generic library package Containers.Bounded_Multiway_Trees has the same contents and semantics as Containers.Multiway_Trees except:
- 3/3 • The pragma Preelaborate is replaced with pragma Pure.
- 4/3 • The type Tree is declared with a discriminant that specifies the capacity (maximum number of elements) as follows:
- 5/3 `type Tree (Capacity : Count_Type) is tagged private;`
- 6/3 • The type Tree needs finalization if and only if type Element_Type needs finalization.
- 6.a/3 **Implementation Note:** {AI05-0212-1} The type Tree cannot depend on package Ada.Finalization unless the element type depends on that package. The objects returned from the Iterator and Reference functions probably do depend on package Ada.Finalization. Restricted environments may need to avoid use of those functions and their associated types.
- 7/3 • The allocation of internal storage includes a check that the capacity is not exceeded, and Capacity_Error is raised if this check fails.
- 8/3 • In procedure Assign, if Source length is greater than Target capacity, then Capacity_Error is propagated.

- Function Copy is declared as follows: 9/3

```
function Copy (Source : Tree; Capacity : Count_Type := 0)
  return List;
```

10/3

If Capacity is 0, then the tree capacity is the count of Source; if Capacity is equal to or greater than Source.Count, the tree capacity equals the value of the Capacity parameter; otherwise, the operation propagates Capacity_Error. 11/3
- {AI05-0136-1} {AI05-0248-1} In the five-parameter procedure Splice_Subtree, if Source is not the same object as Target, and if the sum of Target.Count and Subtree_Node_Count (Position) is greater than Target.Capacity, then Splice_Subtree propagates Capacity_Error. 12/3
- {AI05-0136-1} {AI05-0248-1} In the five-parameter procedure Splice_Children, if Source is not the same object as Target, and if the sum of Target.Count and Subtree_Node_Count (Source_Parent)-1 is greater than Target.Capacity, then Splice_Children propagates Capacity_Error. 13/3

Bounded (Run-Time) Errors

{AI05-0160-1} {AI05-0265-1} It is a bounded error to assign from a bounded tree object while tampering with elements [or cursors] of that object is prohibited. Either Program_Error is raised by the assignment, execution proceeds with the target object prohibiting tampering with elements [or cursors], or execution proceeds normally. 14/3

Proof: Tampering with elements includes tampering with cursors, so we only really need to talk about tampering with elements here; we mention cursors for clarity. 14.a/3

Erroneous Execution

{AI05-0265-1} When a bounded tree object *T* is finalized, if tampering with cursors is prohibited for *T* other than due to an assignment from another tree, then execution is erroneous. 15/3

Reason: This is a tampering event, but since the implementation is not allowed to use Ada.Finalization, it is not possible in a pure Ada implementation to detect this error. (There is no Finalize routine that will be called that could make the check.) Since the check probably cannot be made, the bad effects that could occur (such as an iterator going into an infinite loop or accessing a nonexistent element) cannot be prevented and we have to allow anything. We do allow re-assigning an object that only prohibits tampering because it was copied from another object as that cannot cause any negative effects. 15.a/3

Implementation Requirements

{AI05-0184-1} {AI05-0264-1} For each instance of Containers.Multiway_Trees and each instance of Containers.Bounded_Multiway_Trees, if the two instances meet the following conditions, then the output generated by the Tree'Output or Tree'Write subprograms of either instance shall be readable by the Tree'Input or Tree'Read of the other instance, respectively: 16/3

- {AI05-0184-1} {AI05-0248-1} the Element_Type parameters of the two instances are statically matching subtypes of the same type; and 17/3
- {AI05-0184-1} the output generated by Element_Type'Output or Element_Type'Write is readable by Element_Type'Input or Element_Type'Read, respectively (where Element_Type denotes the type of the two actual Element_Type parameters). 18/3

Implementation Advice

{AI05-0136-1} Bounded tree objects should be implemented without implicit pointers or dynamic allocation. 19/3

Implementation Advice: Bounded tree objects should be implemented without implicit pointers or dynamic allocation. 19.a.1/3

{AI05-0136-1} The implementation advice for procedure Move to minimize copying does not apply. 20/3

20.a.1/3 **Implementation Advice:** The implementation advice for procedure `Move` to minimize copying does not apply to bounded trees.

Extensions to Ada 2005

20.a/3 {*AI05-0136-1*} {*AI05-0184-1*} The generic package `Containers.Bounded_Multiway_Trees` is new.

A.18.26 Array Sorting

1/3 {*AI95-00302-03*} {*AI05-0001-1*} The language-defined generic procedures `Containers.Generic_Array_Sort`, `Containers.Generic_Constrained_Array_Sort`, and `Containers.Generic_Sort` provide sorting on arbitrary array types.

Static Semantics

2/2 {*AI95-00302-03*} The generic library procedure `Containers.Generic_Array_Sort` has the following declaration:

```
3/2  generic
      type Index_Type is (<>);
      type Element_Type is private;
      type Array_Type is array (Index_Type range <>) of Element_Type;
      with function "<" (Left, Right : Element_Type)
        return Boolean is <>;
      procedure Ada.Containers.Generic_Array_Sort (Container : in out Array_Type);
      pragma Pure (Ada.Containers.Generic_Array_Sort);
```

4/2 Reorders the elements of `Container` such that the elements are sorted smallest first as determined by the generic formal "<" operator provided. Any exception raised during evaluation of "<" is propagated.

5/3 {*AI05-0044-1*} {*AI05-0262-1*} The actual function for the generic formal function "<" of `Generic_Array_Sort` is expected to return the same value each time it is called with a particular pair of element values. It should define a strict weak ordering relationship (see A.18); it should not modify `Container`. If the actual for "<" behaves in some other manner, the behavior of the instance of `Generic_Array_Sort` is unspecified. The number of times `Generic_Array_Sort` calls "<" is unspecified.

5.a/2 **Ramification:** This implies swapping the elements, usually including an intermediate copy. This of course means that the elements will be copied. Since the elements are nonlimited, this usually will not be a problem. Note that there is Implementation Advice below that the implementation should use a sort that minimizes copying of elements.

5.b/2 The sort is not required to be stable (and the fast algorithm required will not be stable). If a stable sort is needed, the user can include the original location of the element as an extra "sort key". We considered requiring the implementation to do that, but it is mostly extra overhead -- usually there is something already in the element that provides the needed stability.

6/2 {*AI95-00302-03*} The generic library procedure `Containers.Generic_Constrained_Array_Sort` has the following declaration:

```
7/2  generic
      type Index_Type is (<>);
      type Element_Type is private;
      type Array_Type is array (Index_Type) of Element_Type;
      with function "<" (Left, Right : Element_Type)
        return Boolean is <>;
      procedure Ada.Containers.Generic_Constrained_Array_Sort
        (Container : in out Array_Type);
      pragma Pure (Ada.Containers.Generic_Constrained_Array_Sort);
```

8/2 Reorders the elements of `Container` such that the elements are sorted smallest first as determined by the generic formal "<" operator provided. Any exception raised during evaluation of "<" is propagated.

- {AI05-0044-1}* *{AI05-0262-1}* The actual function for the generic formal function "<" of `Generic_Constrained_Array_Sort` is expected to return the same value each time it is called with a particular pair of element values. It should define a strict weak ordering relationship (see A.18); it should not modify `Container`. If the actual for "<" behaves in some other manner, the behavior of the instance of `Generic_Constrained_Array_Sort` is unspecified. The number of times `Generic_Constrained_Array_Sort` calls "<" is unspecified. 9/3
- {AI05-0001-1}* The generic library procedure `Containers.Generic_Sort` has the following declaration: 9.1/3
- ```

generic
 type Index_Type is (<>);
 with function Before (Left, Right : Index_Type) return Boolean;
 with procedure Swap (Left, Right : Index_Type);
procedure Ada.Containers.Generic_Sort
 (First, Last : Index_Type'Base);
pragma Pure(Ada.Containers.Generic_Sort);

```
- {AI05-0001-1}* *{AI05-0248-1}* Reorders the elements of an indexable structure, over the range `First .. Last`, such that the elements are sorted in the ordering determined by the generic formal function `Before`; `Before` should return `True` if `Left` is to be sorted before `Right`. The generic formal `Before` compares the elements having the given indices, and the generic formal `Swap` exchanges the values of the indicated elements. Any exception raised during evaluation of `Before` or `Swap` is propagated. 9.3/3
- The actual function for the generic formal function `Before` of `Generic_Sort` is expected to return the same value each time it is called with index values that identify a particular pair of element values. It should define a strict weak ordering relationship (see A.18); it should not modify the elements. The actual function for the generic formal `Swap` should exchange the values of the indicated elements. If the actual for either `Before` or `Swap` behaves in some other manner, the behavior of `Generic_Sort` is unspecified. The number of times the `Generic_Sort` calls `Before` or `Swap` is unspecified. 9.4/3
- Implementation Advice*
- {AI95-00302-03}* The worst-case time complexity of a call on an instance of `Containers.Generic_Array_Sort` or `Containers.Generic_Constrained_Array_Sort` should be  $O(N^{**2})$  or better, and the average time complexity should be better than  $O(N^{**2})$ , where  $N$  is the length of the `Container` parameter. 10/2
- Implementation Advice:** `Containers.Generic_Array_Sort` and `Containers.Generic_Constrained_Array_Sort` should have an average time complexity better than  $O(N^{**2})$  and worst case no worse than  $O(N^{**2})$ . 10.a/2
- Discussion:** In other words, we're requiring the use of a sorting algorithm better than  $O(N^{**2})$ , such as Quicksort. No bubble sorts allowed! 10.b/2
- {AI95-00302-03}* `Containers.Generic_Array_Sort` and `Containers.Generic_Constrained_Array_Sort` should minimize copying of elements. 11/2
- Implementation Advice:** `Containers.Generic_Array_Sort` and `Containers.Generic_Constrained_Array_Sort` should minimize copying of elements. 11.a/2
- To be honest:** We do not mean "absolutely minimize" here; we're not intending to require a single copy for each element. Rather, we want to suggest that the sorting algorithm chosen is one that does not copy items unnecessarily. Bubble sort would not meet this advice, for instance. 11.b/2
- {AI05-0248-1}* The worst-case time complexity of a call on an instance of `Containers.Generic_Sort` should be  $O(N^{**2})$  or better, and the average time complexity should be better than  $O(N^{**2})$ , where  $N$  is the difference between the `Last` and `First` parameters plus 1. 12/3
- Implementation Advice:** `Containers.Generic_Sort` should have an average time complexity better than  $O(N^{**2})$  and worst case no worse than  $O(N^{**2})$ . 12.a.1/3

13/3 {AI05-0248-1} Containers.Generic\_Sort should minimize calls to the generic formal Swap.

13.a.1/3 **Implementation Advice:** Containers.Generic\_Sort should minimize calls to the generic formal Swap.

*Extensions to Ada 95*

13.a/2 {AI95-00302-03} The generic procedures Containers.Generic\_Array\_Sort and Containers.Generic\_Constrained\_Array\_Sort are new.

*Extensions to Ada 2005*

13.b/3 {AI05-0001-1} {AI05-0248-1} The generic procedure Containers.Generic\_Sort is new.

*Wording Changes from Ada 2005*

13.c/3 {AI05-0044-1} **Correction:** Redefined "<" actuals to require a strict weak ordering; the old definition allowed indeterminant comparisons that would not have worked in a sort.

## A.18.27 The Generic Package Containers.Synchronized\_Queue\_Interfaces

1/3 {AI05-0159-1} The language-defined generic package Containers.Synchronized\_Queue\_Interfaces provides interface type Queue, and a set of operations for that type. Interface Queue specifies a first-in, first-out queue.

*Static Semantics*

2/3 {AI05-0159-1} The generic library package Containers.Synchronized\_Queue\_Interfaces has the following declaration:

```

3/3 generic
 type Element_Type is private;
 package Ada.Containers.Synchronized_Queue_Interfaces is
 pragma Pure(Synchronized_Queue_Interfaces);
4/3 type Queue is synchronized interface;
5/3 procedure Enqueue
 (Container : in out Queue;
 New_Item : in Element_Type) is abstract
 with Synchronization => By_Entry;
6/3 procedure Dequeue
 (Container : in out Queue;
 Element : out Element_Type) is abstract
 with Synchronization => By_Entry;
7/3 function Current_Use (Container : Queue) return Count_Type is abstract;
 function Peak_Use (Container : Queue) return Count_Type is abstract;
8/3 end Ada.Containers.Synchronized_Queue_Interfaces;
9/3 procedure Enqueue
 (Container : in out Queue;
 New_Item : in Element_Type) is abstract;

```

10/3 {AI05-0159-1} {AI05-0262-1} {AI05-0264-1} A queue type that implements this interface is allowed to have a bounded *capacity*. If the queue object has a bounded capacity, and the number of existing elements equals the capacity, then Enqueue blocks until storage becomes available; otherwise, Enqueue does not block. In any case, it then copies New\_Item onto the queue.

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |        |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|
| <b>procedure</b> Dequeue                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 11/3   |
| (Container : <b>in out</b> Queue;<br>Element : <b>out</b> Element_Type) <b>is abstract</b> ;                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |        |
| {AI05-0159-1} {AI05-0251-1} If the queue is empty, then Dequeue blocks until an item becomes available. In any case, it then assigns the element at the head of the queue to Element, and removes it from the queue.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | 12/3   |
| <b>function</b> Current_Use (Container : Queue) <b>return</b> Count_Type <b>is abstract</b> ;                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | 13/3   |
| {AI05-0159-1} Returns the number of elements currently in the queue.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | 14/3   |

| {AI05-0159-1} Returns the maximum number of elements that have been in the queue at any one time.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | 16/3   |
| NOTES                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |        |
| 51 {AI05-0251-1} Unlike other language-defined containers, there are no queues whose element types are indefinite. Elements of an indefinite type can be handled by defining the element of the queue to be a holder container (see A.18.18) of the indefinite type, or to be an explicit access type that designates the indefinite type.                                                                                                                                                                                                                                                                                                                                                                | 17/3   |
| <b>Reason:</b> There are no indefinite queues, as a useful definition for Dequeue is not possible. Dequeue cannot be a function, as Ada does not have entries that are functions (thus conditional and timed calls would not be possible). Moreover, protected functions do not allow modifying the queue object (thus it doesn't work even if we decided we didn't care about conditional and timed calls). If Dequeue is an entry, then the dequeued object would have to be an <b>out</b> parameter and that would require the queue client to guess the tag and constraints of the value that will be dequeued (otherwise Constraint_Error would be raised), and that is rarely going to be possible. | 17.a/3 |
| <i>Extensions to Ada 2005</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |        |

```

10/3 end Ada.Containers.Unbounded_Synchronized_Queues;

```

11/3 {AI05-0159-1} The type Queue is used to represent task-safe queues.

12/3 {AI05-0159-1} The capacity for instances of type Queue is unbounded.

12.a/3 **Ramification:** Enqueue never blocks; if more storage is needed for a new element, it is allocated dynamically. We don't need to explicitly specify that Queue needs finalization, because it is visibly protected.

12.b/3 **Discussion:** Nested package Implementation can be used to declare the types needed to implement the protected type Queue. This nested package is necessary as types cannot be declared in the private part of a protected type, and the types have to be declared within the generic unit in order to depend on the types imported with package Queue\_Interfaces. Clients should never depend on the contents of nested package Implementation.

*Extensions to Ada 2005*

12.c/3 {AI05-0159-1} The generic package Containers.Unbounded\_Synchronized\_Queues is new.

## A.18.29 The Generic Package Containers.Bounded\_Synchronized\_Queues

*Static Semantics*

1/3 {AI05-0159-1} The language-defined generic package Containers.Bounded\_Synchronized\_Queues provides type Queue, which implements the interface type Containers.Synchronized\_Queue\_Interfaces.Queue.

```

2/3 with System;
 with Ada.Containers.Synchronized_Queue_Interfaces;

```

8/3 private
 ... -- not specified by the language
 end Queue;

```

```

9/3 private
10/3 ... -- not specified by the language
11/3 end Ada.Containers.Unbounded_Priority_Queues;

```

12/3 {AI05-0159-1} The type Queue is used to represent task-safe priority queues.

13/3 {AI05-0159-1} The capacity for instances of type Queue is unbounded.

14/3 {AI05-0159-1} Two elements *E1* and *E2* are equivalent if Before(Get\_Priority(*E1*), Get\_Priority(*E2*)) and Before(Get\_Priority(*E2*), Get\_Priority(*E1*)) both return False.

15/3 {AI05-0159-1} {AI05-0248-1} The actual functions for Get\_Priority and Before are expected to return the same value each time they are called with the same actuals, and should not modify their actuals. Before should define a strict weak ordering relationship (see A.18). If the actual functions behave in some other manner, the behavior of Unbounded\_Priority\_Queues is unspecified.

16/3 {AI05-0159-1} Enqueue inserts an item according to the order specified by the Before function on the result of Get\_Priority on the elements; Before should return True if Left is to be inserted before Right. If the queue already contains elements equivalent to New\_Item, then it is inserted after the existing equivalent elements.

16.a/3 **Ramification:** Enqueue never blocks; if more storage is needed for a new element, it is allocated dynamically. We don't need to explicitly specify that Queue needs finalization, because it is visibly protected.

17/3 {AI05-0159-1} {AI05-0251-1} {AI05-0262-1} For a call on Dequeue\_Only\_High\_Priority, if the head of the nonempty queue is *E*, and the function Before(At\_Least, Get\_Priority(*E*)) returns False, then *E* is assigned to Element and then removed from the queue, and Success is set to True; otherwise, Success is set to False and Element is unchanged.

17.a/3 **Ramification:** {AI05-0251-1} Unlike Dequeue, Dequeue\_Only\_High\_Priority is not blocking; it always returns immediately.

17.b/3 **Reason:** {AI05-0251-1} The use of Before is "backwards" so that it acts like ">=" (it is defined similarly to ">"); thus we dequeue only when it is False.

#### *Extensions to Ada 2005*

17.c/3 {AI05-0159-1} {AI05-0251-1} The generic package Containers.Unbounded\_Priority\_Queues is new.

## A.18.31 The Generic Package Containers.Bounded\_Priority\_Queues

### *Static Semantics*

1/3 {AI05-0159-1} The language-defined generic package Containers.Bounded\_Priority\_Queues provides type Queue, which implements the interface type Containers.Synchronized\_Queue\_Interfaces.Queue.

|                                                                                                                                     |          |
|-------------------------------------------------------------------------------------------------------------------------------------|----------|
| <code>with System;</code>                                                                                                           | 2/3      |

## A.18.32 Example of Container Use

Examples

```

1/3 {AI05-0212-1} The following example is an implementation of Dijkstra's shortest path algorithm in a
 directed graph with positive distances. The graph is represented by a map from nodes to sets of edges.
2/3 with Ada.Containers.Vectors;
 with Ada.Containers.Doubly_Linked_Lists;
 use Ada.Containers;
 generic
 type Node is range <>;
 package Shortest_Paths is
 type Distance is new Float range 0.0 .. Float'Last;
 type Edge is record
 To, From : Node;
 Length : Distance;
 end record;
3/3 package Node_Maps is new Vectors (Node, Node);
 -- The algorithm builds a map to indicate the node used to reach a given
 -- node in the shortest distance.
4/3 package Adjacency_Lists is new Doubly_Linked_Lists (Edge);
 use Adjacency_Lists;
5/3 package Graphs is new Vectors (Node, Adjacency_Lists.List);
6/3 package Paths is new Doubly_Linked_Lists (Node);
7/3 function Shortest_Path
 (G : Graphs.Vector; Source : Node; Target : Node) return Paths.List
 with Pre => G (Source) /= Adjacency_Lists.Empty_List;
8/3 end Shortest_Paths;
9/3 package body Shortest_Paths is
 function Shortest_Path
 (G : Graphs.Vector; Source : Node; Target : Node) return Paths.List
 is
 use Adjacency_Lists, Node_Maps, Paths, Graphs;
 Reached : array (Node) of Boolean := (others => False);
 -- The set of nodes whose shortest distance to the source is known.
10/3 {AI05-0299-1} Reached_From : array (Node) of Node;
 So_Far : array (Node) of Distance := (others => Distance'Last);
 The_Path : Paths.List := Paths.Empty_List;
 Nearest_Distance : Distance;
 Next : Node;
 begin
 So_Far(Source) := 0.0;
11/3 while not Reached(Target) loop
 Nearest_Distance := Distance'Last;
12/3 -- Find closest node not reached yet, by iterating over all nodes.
 -- A more efficient algorithm uses a priority queue for this step.
13/3 Next := Source;
 for N in Node'First .. Node'Last loop
 if not Reached(N)
 and then So_Far(N) < Nearest_Distance then
 Next := N;
 Nearest_Distance := So_Far(N);
 end if;
 end loop;
14/3 {AI05-0299-1} if Nearest_Distance = Distance'Last then
 -- No next node found, graph is not connected
 return Paths.Empty_List;
 end Shortest_Path;
 end package Shortest_Paths;

```

```

else
 Reached(Next) := True;
end if;
-- Update minimum distance to newly reachable nodes.
{AI05-0299-1}
for E of G (Next) loop
 if not Reached(E.To) then
 Nearest_Distance := E.Length + So_Far(Next);
 if Nearest_Distance < So_Far(E.To) then
 Reached_From(E.To) := Next;
 So_Far(E.To) := Nearest_Distance;
 end if;
 end if;
end loop;
-- Rebuild path from target to source.
declare
 N : Node := Target;
begin
 while N /= Source loop
 N := Reached_From(N);
 Prepend (The_Path, N);
 end loop;
end;
return The_Path;
end;
end Shortest_Paths;

```

{AI05-0212-1} Note that the effect of the Constant\_Indexing aspect (on type Vector) and the Implicit\_Dereference aspect (on type Reference\_Type) is that

```

G (Next)

```

{AI05-0212-1} is a convenient short hand for

```

G.Constant_Reference (Next).Element.all

```

{AI05-0212-1} Similarly, the effect of the loop:

```

for E of G (Next) loop
 if not Reached(E.To) then
 ...
 end if;
end loop;

```

{AI05-0212-1} is the same as:

```

for C in G (Next).Iterate loop
 declare
 E : Edge renames G (Next)(C).all;
 begin
 if not Reached(E.To) then
 ...
 end if;
 end;
end loop;

```

30/3 {AI05-0212-1} which is the same as:

```

31/3 declare
 L : Adjacency_Lists.List renames G (Next);
 C : Adjacency_Lists.Cursor := L.First;
 begin
 while Has_Element (C) loop
 declare
 E : Edge renames L(C).all;
 begin
 if not Reached(E.To) then
 . . .
 end if;
 end;
 C := L.Next (C);
 end loop;
 end;
```

*Wording Changes from Ada 2005*

31.a/3 {AI05-0212-1} This example of container use is new.

## A.19 The Package Locales

1/3 {AI05-0127-2} {AI05-0248-1} A *locale* identifies a geopolitical place or region and its associated language, which can be used to determine other internationalization-related characteristics.

*Static Semantics*

2/3 {AI05-0127-2} The library package Locales has the following declaration:

```

3/3 package Ada.Locales is
 pragma Preelaborate(Locales);
 pragma Remote_Types(Locales);
4/3 type Language_Code is array (1 .. 3) of Character range 'a' .. 'z';
 type Country_Code is array (1 .. 2) of Character range 'A' .. 'Z';
5/3 Language_Unknown : constant Language_Code := "und";
 Country_Unknown : constant Country_Code := "ZZ";
6/3 function Language return Language_Code;
 function Country return Country_Code;
7/3 end Ada.Locales;
```

8/3 {AI05-0127-2} {AI05-0233-1} The *active locale* is the locale associated with the partition of the current task.

8.a/3 **Implementation Note:** {AI05-0233-1} Some environments define both a system locale and the locale of the current user. For such environments, the active locale is that of current user if any; otherwise (as in a partition running on a server without a user), the system locale should be used.

9/3 {AI05-0127-2} Language\_Code is a lower-case string representation of an ISO 639-3 alpha-3 code that identifies a language.

9.a/3 **Discussion:** Some common language codes are: "eng" – English; "fra" – French; "deu" – German; "zho" – Chinese. These are the same codes as used by POSIX systems. We considered including constants for the most common languages, but that was rejected as the likely source of continual arguments about the constant names and which languages are important enough to include.

10/3 {AI05-0127-2} Country\_Code is an upper-case string representation of an ISO 3166-1 alpha-2 code that identifies a country.

10.a/3 **Discussion:** Some common country codes are: "CA" – Canada; "FR" – France; "DE" – Germany; "IT" – Italy; "ES" – Spain; "GB" – United Kingdom; "US" – United States. These are the same codes as used by POSIX systems. We didn't include any country constants for the same reasons that we didn't include any language constants.

{AI05-0127-2} {AI05-0248-1} Function `Language` returns the code of the language associated with the active locale. If the `Language_Code` associated with the active locale cannot be determined from the environment, then `Language` returns `Language_Unknown`. 11/3

{AI05-0127-2} {AI05-0248-1} Function `Country` returns the code of the country associated with the active locale. If the `Country_Code` associated with the active locale cannot be determined from the environment, then `Country` returns `Country_Unknown`. 12/3

*Extensions to Ada 2005*

{AI05-0127-2} {AI05-0233-1} Package `Locales` is new. 12.a/3

# Annex B

## (normative)

### Interface to Other Languages

This Annex describes features for writing mixed-language programs. General interface support is presented first; then specific support for C, COBOL, and Fortran is defined, in terms of language interface packages for each of these languages. 1

**Ramification:** This Annex is not a “Specialized Needs” annex. Every implementation must support all nonoptional features defined here (mainly the package Interfaces). 1.a

#### *Language Design Principles*

Ada should have strong support for mixed-language programming. 1.b

#### *Implementation Requirements*

{AI05-0229-1} {AI05-0262-1} {AI05-0299-1} Support for interfacing to any foreign language is optional. However, an implementation shall not provide any optional aspect, attribute, library unit, or pragma having the same name as an aspect, attribute, library unit, or pragma (respectively) specified in the subclauses of this Annex unless the provided construct is either as specified in those subclauses or is more limited in capability than that required by those subclauses. A program that attempts to use an unsupported capability of this Annex shall either be identified by the implementation before run time or shall raise an exception at run time. 2/3

**Discussion:** The intent is that the same rules apply for the optional parts of language interfacing as apply for Specialized Needs Annexes. See 1.1.3 for a discussion of the purpose of these rules. 2.a/3

#### *Extensions to Ada 83*

Much of the functionality in this Annex is new to Ada 95. 2.b

#### *Wording Changes from Ada 83*

This Annex contains what used to be RM83-13.8. 2.c

#### *Wording Changes from Ada 2005*

{AI05-0262-1} Moved the clarification that interfacing to foreign languages is optional and has the same restrictions as a Specialized Needs Annex here. 2.d/3

## B.1 Interfacing Aspects

{AI05-0229-1} An *interfacing* aspect is a representation aspect that is one of the aspects Import, Export, Link\_Name, External\_Name, or Convention. 0.1/3

{AI05-0229-1} {AI05-0269-1} Specifying the Import aspect to have the value True is used to import an entity defined in a foreign language into an Ada program, thus allowing a foreign-language subprogram to be called from Ada, or a foreign-language variable to be accessed from Ada. In contrast, specifying the Export aspect to have the value True is used to export an Ada entity to a foreign language, thus allowing an Ada subprogram to be called from a foreign language, or an Ada object to be accessed from a foreign language. The Import and Export aspects are intended primarily for objects and subprograms, although implementations are allowed to support other entities. The Link\_Name and External\_Name aspects are used to specify the link name and external name, respectively, to be used to identify imported or exported entities in the external environment. 1/3

**Aspect Description for Import:** Entity is imported from another language. 1.a/3

- 1.b/3        **Aspect Description for Export:** Entity is exported to another language.
- 1.c/3        **Aspect Description for External\_Name:** Name used to identify an imported or exported entity.
- 1.d/3        **Aspect Description for Link\_Name:** Linker symbol used to identify an imported or exported entity.
- 2/3        {AI05-0229-1} The Convention aspect is used to indicate that an Ada entity should use the conventions of another language. It is intended primarily for types and “callback” subprograms. For example, “**with** Convention => Fortran” on the declaration of an array type Matrix implies that Matrix should be represented according to the conventions of the supported Fortran implementation, namely column-major order.
- 2.a/3        **Aspect Description for Convention:** Calling convention or other convention used for interfacing to other languages.
- 3        A pragma Linker\_Options is used to specify the system linker parameters needed when a given compilation unit is included in a partition.

*Syntax*

- 4/3        {AI05-0229-1} The form of a pragma Linker\_Options is as follows:  
*Paragraphs 5 through 7 were moved to Annex J, “Obsolescent Features”.*
- 8        **pragma** Linker\_Options(*string\_expression*);
- 9        A pragma Linker\_Options is allowed only at the place of a **declarative\_item**.
- 9.1/3        *This paragraph was deleted.* {8652/0058} {AI95-00036-01} {AI05-0229-1}

*Name Resolution Rules*

- 9.2/3        {AI05-0229-1} The Import and Export aspects are of type Boolean.
- 10/3        {AI05-0229-1} The Link\_Name and External\_Name aspects are of type String.
- 10.a/3        **Ramification:** There is no language-defined support for external or link names of type Wide\_String, or of other string types. Implementations may, of course, have additional aspects for that purpose. Note that allowing both String and Wide\_String in the same **aspect\_definition** would cause ambiguities.
- 10.1/3        {AI05-0229-1} The expected type for the *string\_expression* in pragma Linker\_Options is String.

*Legality Rules*

- 11/3        {AI05-0229-1} The aspect Convention shall be specified by a *convention\_identifier* which shall be the name of a *convention*. The convention names are implementation defined, except for certain language-defined ones, such as Ada and Intrinsic, as explained in 6.3.1, “Conformance Rules”. [Additional convention names generally represent the calling conventions of foreign languages, language implementations, or specific run-time models.] The convention of a callable entity is its *calling convention*.
- 11.a        **Implementation defined:** Implementation-defined convention names.
- 11.b        **Discussion:** We considered representing the convention names using an enumeration type declared in System. Then, *convention\_identifier* would be changed to *convention\_name*, and we would make its expected type be the enumeration type. We didn't do this because it seems to introduce extra complexity, and because the list of available languages is better represented as the list of children of package Interfaces — a more open-ended sort of list.
- 12        If *L* is a *convention\_identifier* for a language, then a type T is said to be *compatible with convention L*, (alternatively, is said to be an *L-compatible type*) if any of the following conditions are met:
- 13        • T is declared in a language interface package corresponding to *L* and is defined to be *L-compatible* (see B.3, B.3.1, B.3.2, B.4, B.5),
- 14/3        • {AI05-0229-1} Convention *L* has been specified for T, and T is *eligible for convention L*; that is:
- 15        • T is an array type with either an unconstrained or statically-constrained first subtype, and its component type is *L-compatible*,

- T is a record type that has no discriminants and that only has components with statically-constrained subtypes, and each component type is *L*-compatible, 16
  - {*AI05-0002-1*} T is an access-to-object type, its designated type is *L*-compatible, and its designated subtype is not an unconstrained array subtype, 17/3
  - T is an access-to-subprogram type, and its designated profile's parameter and result types are all *L*-compatible. 18
  - T is derived from an *L*-compatible type, 19
  - The implementation permits T as an *L*-compatible type. 20
    - Discussion:** For example, an implementation might permit Integer as a C-compatible type, though the C type to which it corresponds might be different in different environments. 20.a
  - {*AI05-0229-1*} If the Convention aspect is specified for a type, then the type shall either be compatible with or eligible for the specified convention. 21/3
    - Ramification:** {*AI05-0229-1*} If a type is derived from an *L*-compatible type, the derived type is by default *L*-compatible, but it is also permitted to specify the Convention aspect for the derived type. 21.a/3
    - {*AI05-0229-1*} It is permitted to specify the Convention aspect for an incomplete type, but in the complete declaration each component must be *L*-compatible. 21.b/3
    - {*AI05-0229-1*} If each component of a record type is *L*-compatible, then the record type itself is only *L*-compatible if it has a specified Convention. 21.c/3
  - {*AI05-0229-1*} Notwithstanding any rule to the contrary, a declaration with a True Import aspect shall not have a completion. 22/3
    - Discussion:** {*AI05-0229-1*} For declarations of deferred constants and subprograms, we explicitly mention that no completion is allowed when aspect Import is True. For other declarations that require completions, we ignore the possibility of the aspect Import being True. Nevertheless, if an implementation chooses to allow specifying aspect Import to be True for the declaration of a task, protected type, incomplete type, private type, etc., it may do so, and the normal completion is then not allowed for that declaration. 22.a/3
  - {*AI05-0229-1*} An entity with a True Import aspect (or Export aspect) is said to be *imported* (respectively, *exported*). An entity shall not be both imported and exported. 23/3
  - The declaration of an imported object shall not include an explicit initialization expression. [Default initializations are not performed.] 24
    - Proof:** This follows from the “Notwithstanding ...” wording in the Dynamics Semantics paragraphs below. 24.a
  - {*AI05-0229-1*} The type of an imported or exported object shall be compatible with the specified Convention aspect, if any. 25/3
    - Ramification:** This implies, for example, that importing an Integer object might be illegal, whereas importing an object of type Interfaces.C.int would be permitted. 25.a
  - {*AI05-0229-1*} For an imported or exported subprogram, the result and parameter types shall each be compatible with the specified Convention aspect, if any. 26/3
  - {*AI05-0229-1*} The `aspect_definition` (if any) used to directly specify an Import, Export, External\_Name, or Link\_Name aspect shall be a static expression. The *string\_expression* of a pragma Linker\_Options shall be static. An External\_Name or Link\_Name aspect shall be specified only for an entity that is either imported or exported. 27/3
- Static Semantics*
- Paragraphs 28 and 29 were deleted.*
- {*AI05-0229-1*} The Convention aspect represents the calling convention or representation convention of the entity. For an access-to-subprogram type, it represents the calling convention of designated subprograms. In addition: 30/3

- 31/3 • A True Import aspect indicates that the entity is defined externally (that is, outside the Ada program). This aspect is never inherited; if not directly specified, the Import aspect is False.
  - 32/3 • A True Export aspect indicates that the entity is used externally. This aspect is never inherited; if not directly specified, the Export aspect is False.
  - 33/3 • For an entity with a True Import or Export aspect, an external name, link name, or both may also be specified.
- 34 An *external name* is a string value for the name used by a foreign language program either for an entity that an Ada program imports, or for referring to an entity that an Ada program exports.
- 35 A *link name* is a string value for the name of an exported or imported entity, based on the conventions of the foreign language's compiler in interfacing with the system's linker tool.
- 36 The meaning of link names is implementation defined. If neither a link name nor the Address attribute of an imported or exported entity is specified, then a link name is chosen in an implementation-defined manner, based on the external name if one is specified.
- 36.a **Implementation defined:** The meaning of link names.
- 36.b **Ramification:** For example, an implementation might always prepend "\_", and then pass it to the system linker.
- 36.c **Implementation defined:** The manner of choosing link names when neither the link name nor the address of an imported or exported entity is specified.
- 36.d **Ramification:** Normally, this will be the entity's defining name, or some simple transformation thereof.
- 37 Pragma `Linker_Options` has the effect of passing its string argument as a parameter to the system linker (if one exists), if the immediately enclosing compilation unit is included in the partition being linked. The interpretation of the string argument, and the way in which the string arguments from multiple `Linker_Options` pragmas are combined, is implementation defined.
- 37.a **Implementation defined:** The effect of pragma `Linker_Options`.

*Dynamic Semantics*

- 38/3 *{AI05-0229-1}* Notwithstanding what this International Standard says elsewhere, the elaboration of a declaration with a True Import aspect does not create the entity. Such an elaboration has no other effect than to allow the defining name to denote the external entity.
- 38.a **Ramification:** This implies that default initializations are skipped. (Explicit initializations are illegal.) For example, an imported access object is *not* initialized to **null**.
- 38.b/3 *This paragraph was deleted. {AI05-0229-1}*
- 38.c/3 **Discussion:** *{AI05-0229-1}* This “notwithstanding” wording is better than saying “unless aspect Import is True” on every definition of elaboration. It says we recognize the contradiction, and this rule takes precedence.

*Erroneous Execution*

- 38.1/3 *{AI95-00320-01}* *{AI05-0229-1}* It is the programmer's responsibility to ensure that the use of interfacing aspects does not violate Ada semantics; otherwise, program execution is erroneous.

*Implementation Advice*

- 39/3 *{AI05-0229-1}* If an implementation supports Export for a given language, then it should also allow the main subprogram to be written in that language. It should support some mechanism for invoking the elaboration of the Ada library units included in the system, and for invoking the finalization of the environment task. On typical systems, the recommended mechanism is to provide two subprograms whose link names are "adainit" and "adafinal". Adainit should contain the elaboration code for library units. Adafinal should contain the finalization code. These subprograms should have no effect the second and subsequent time they are called.

- Implementation Advice:** If Export is supported for a language, the main program should be able to be written in that language. Subprograms named "adainit" and "adafinal" should be provided for elaboration and finalization of the environment task. 39.a.1/3
- Ramification:** For example, if the main subprogram is written in C, it can call adainit before the first call to an Ada subprogram, and adafinal after the last. 39.a
- {AI05-0229-1} {AI05-0269-1} Automatic elaboration of preelaborated packages should be provided when specifying the Export aspect as True is supported. 40/3
- Implementation Advice:** Automatic elaboration of preelaborated packages should be provided when specifying the Export aspect as True is supported. 40.a.1/3
- {AI05-0229-1} For each supported convention *L* other than Intrinsic, an implementation should support specifying the Import and Export aspects for objects of *L*-compatible types and for subprograms, and the Convention aspect for *L*-eligible types and for subprograms, presuming the other language has corresponding features. Specifying the Convention aspect need not be supported for scalar types. 41/3
- Implementation Advice:** For each supported convention *L* other than Intrinsic, specifying the aspects Import and Export should be supported for objects of *L*-compatible types and for subprograms, and aspect Convention should be supported for *L*-eligible types and for subprograms. 41.a.1/3
- Reason:** {AI05-0229-1} Specifying aspect Convention is not necessary for scalar types, since the language interface packages declare scalar types corresponding to those provided by the respective foreign languages. 41.a/3
- Implementation Note:** {AI95-00114-01} If an implementation supports interfacing to the C++ entities not supported by B.3, it should do so via the convention identifier C\_Plus\_Plus (in addition to any C++-implementation-specific ones). 41.b/2
- Reason:** {AI95-00114-01} The reason for giving the advice about C++ is to encourage uniformity among implementations, given that the name of the language is not syntactically legal as an identifier. 41.c/2
- NOTES
- 1 {AI05-0229-1} Implementations may place restrictions on interfacing aspects; for example, requiring each exported entity to be declared at the library level. 42/3
- Proof:** Arbitrary restrictions are allowed by 13.1. 42.a
- Ramification:** Such a restriction might be to disallow them altogether. Alternatively, the implementation might allow them only for certain kinds of entities, or only for certain conventions. 42.b
- 2 {AI05-0229-1} The Convention aspect in combination with the Import aspect indicates the conventions for accessing external entities. It is possible that the actual entity is written in assembly language, but reflects the conventions of a particular language. For example, `with Convention => Ada` can be used to interface to an assembly language routine that obeys the Ada compiler's calling conventions. 43/3
- 3 {AI05-0229-1} To obtain "call-back" to an Ada subprogram from a foreign language environment, the Convention aspect should be specified both for the access-to-subprogram type and the specific subprogram(s) to which 'Access is applied. 44/3
- Paragraphs 45 and 46 were deleted.*
- 4 See also 13.8, "Machine Code Insertions". 47
- Ramification:** {AI05-0229-1} The Intrinsic convention (see 6.3.1) implies that the entity is somehow "built in" to the implementation. Thus, it generally does not make sense for users to specify Intrinsic along with specifying that the entity is imported. The intention is that only implementations will specify Intrinsic for an imported entity. The language also defines certain subprograms to be Intrinsic. 47.a/3
- Discussion:** {AI05-0229-1} There are many imaginable interfacing aspects that don't make any sense. For example, setting the Convention of a protected procedure to Ada is probably wrong. Rather than enumerating all such cases, however, we leave it up to implementations to decide what is sensible. 47.b/3
- 5 {AI05-0229-1} If both External\_Name and Link\_Name are specified for a given entity, then the External\_Name is ignored. 48/3
- This paragraph was deleted. {AI95-00320-01}* 49/2

*Examples*

50 *Example of interfacing pragmas:*

```
51/3 {AI05-0229-1} {AI05-0269-1} package Fortran_Library is
 function Sqrt (X : Float) return Float
 with Import => True, Convention => Fortran;
 type Matrix is array (Natural range <>, Natural range <>) of Float
 with Convention => Fortran;
 function Invert (M : Matrix) return Matrix
 with Import => True, Convention => Fortran;
end Fortran_Library;
```

*Extensions to Ada 83*

51.a Interfacing pragmas are new to Ada 95. Pragma Import replaces Ada 83's pragma Interface. Existing implementations can continue to support pragma Interface for upward compatibility.

*Wording Changes from Ada 95*

51.b/2 {8652/0058} {AI95-00036-01} **Corrigendum:** Clarified that pragmas Import and Export work like a subprogram call; parameters cannot be omitted unless named notation is used. (Reordering is still not permitted, however.)

51.c/2 {AI95-00320-01} Added wording to say all bets are off if foreign code doesn't follow the semantics promised by the Ada specifications.

*Incompatibilities With Ada 2005*

51.d/3 {AI05-0002-1} **Correction:** Access types that designate unconstrained arrays are no longer defined to be *L*-compatible. Such access-to-arrays require bounds information, which is likely to be incompatible with a foreign language. The change will allow (but not require) compilers to reject bad uses, which probably will not work anyway. Note that implementations can still support any type that it wants as *L*-compatible; such uses will not be portable, however. As such, there should be little existing code that will be impacted (compilers probably already rejected cases that could not be translated, whether or not the language allowed doing so formally).

*Extensions to Ada 2005*

51.e/3 {AI05-0229-1} Aspects Convention, Import, Export, Link\_Name, and External\_Name are new; pragmas Convention, Import, and Export are now obsolescent.

## B.2 The Package Interfaces

1 Package Interfaces is the parent of several library packages that declare types and other entities useful for interfacing to foreign languages. It also contains some implementation-defined types that are useful across more than one language (in particular for interfacing to assembly language).

1.a **Implementation defined:** The contents of the visible part of package Interfaces and its language-defined descendants.

*Static Semantics*

2 The library package Interfaces has the following skeletal declaration:

```
3 package Interfaces is
4 pragma Pure (Interfaces);
5 type Integer_n is range -2**(n-1) .. 2**(n-1) - 1; --2's complement
 type Unsigned_n is mod 2**n;
```

```

function Shift_Left (Value : Unsigned_n; Amount : Natural)
 return Unsigned_n;
function Shift_Right (Value : Unsigned_n; Amount : Natural)
 return Unsigned_n;
function Shift_Right_Arithmetic (Value : Unsigned_n; Amount : Natural)
 return Unsigned_n;
function Rotate_Left (Value : Unsigned_n; Amount : Natural)
 return Unsigned_n;
function Rotate_Right (Value : Unsigned_n; Amount : Natural)
 return Unsigned_n;
...
end Interfaces;

```

*Implementation Requirements*

An implementation shall provide the following declarations in the visible part of package Interfaces: 7

- Signed and modular integer types of  $n$  bits, if supported by the target architecture, for each  $n$  that is at least the size of a storage element and that is a factor of the word size. The names of these types are of the form `Integer_n` for the signed types, and `Unsigned_n` for the modular types; 8

**Ramification:** For example, for a typical 32-bit machine the corresponding types might be `Integer_8`, `Unsigned_8`, `Integer_16`, `Unsigned_16`, `Integer_32`, and `Unsigned_32`. 8.a

The wording above implies, for example, that `Integer_16'Size = Unsigned_16'Size = 16`. Unchecked conversions between same-Sized types will work as expected. 8.b

- For each such modular type in Interfaces, shifting and rotating subprograms as specified in the declaration of Interfaces above. These subprograms are Intrinsic. They operate on a bit-by-bit basis, using the binary representation of the value of the operands to yield a binary representation for the result. The Amount parameter gives the number of bits by which to shift or rotate. For shifting, zero bits are shifted in, except in the case of `Shift_Right_Arithmetic`, where one bits are shifted in if Value is at least half the modulus. 9

**Reason:** We considered making shifting and rotating be primitive operations of all modular types. However, it is a design principle of Ada that all predefined operations should be operators (not functions named by identifiers). (Note that an early version of Ada had "abs" as an identifier, but it was changed to a reserved word operator before standardization of Ada 83.) This is important because the implicit declarations would hide nonoverloadable declarations with the same name, whereas operators are always overloadable. Therefore, we would have had to make shift and rotate into reserved words, which would have been upward incompatible, or else invent new operator symbols, which seemed like too much mechanism. 9.a

- Floating point types corresponding to each floating point format fully supported by the hardware. 10

**Implementation Note:** The names for these floating point types are not specified. However, if IEEE arithmetic is supported, then the names should be `IEEE_Float_32` and `IEEE_Float_64` for single and double precision, respectively. 10.a

*Implementation Permissions*

An implementation may provide implementation-defined library units that are children of Interfaces, and may add declarations to the visible part of Interfaces in addition to the ones defined above. 11

**Implementation defined:** Implementation-defined children of package Interfaces. 11.a/2

{AI95-00204-01} {AI05-0229-1} A child package of package Interfaces with the name of a convention may be provided independently of whether the convention is supported by the Convention aspect and vice versa. Such a child package should contain any declarations that would be useful for interfacing to the language (implementation) represented by the convention. Any declarations useful for interfacing to any language on the given hardware architecture should be provided directly in Interfaces. 11.1/3

**Ramification:** For example, package Interfaces.XYZ\_Pascal might contain declarations of types that match the data types provided by the XYZ implementation of Pascal, so that it will be more convenient to pass parameters to a subprogram whose convention is XYZ\_Pascal. 11.b/2

*Implementation Advice*

- 12/2 *This paragraph was deleted.* {AI95-00204-01}
- 12.a/2 *This paragraph was deleted.*
- 13/3 {AI05-0299-1} An implementation supporting an interface to C, COBOL, or Fortran should provide the corresponding package or packages described in the following subclauses.
- 13.a.1/2 **Implementation Advice:** If an interface to C, COBOL, or Fortran is provided, the corresponding package or packages described in Annex B, “Interface to Other Languages” should also be provided.
- 13.a **Implementation Note:** The intention is that an implementation might support several implementations of the foreign language: Interfaces.This\_Fortran and Interfaces.That\_Fortran might both exist. The “default” implementation, overridable by the user, should be declared as a renaming:
- 13.b `package Interfaces.Fortran renames Interfaces.This_Fortran;`
- Wording Changes from Ada 95*
- 13.c/2 {AI95-00204-01} Clarified that interfacing to foreign languages is optional and has the same restrictions as a Specialized Needs Annex.
- Wording Changes from Ada 2005*
- 13.d/3 {AI05-0262-1} Move the restrictions on implementations of optional features to the start of this Annex.

**B.3 Interfacing with C and C++**

- 1/3 {8652/0059} {AI95-00131-01} {AI95-00376-01} {AI05-0229-1} The facilities relevant to interfacing with the C language and the corresponding subset of the C++ language are the package Interfaces.C and its children, and support for specifying the Convention aspect with *convention\_identifiers* C and C\_Pass\_By\_Copy.
- 2/3 {AI95-00376-01} {AI95-0262-1} {AI95-0299-1} The package Interfaces.C contains the basic types, constants, and subprograms that allow an Ada program to pass scalars and strings to C and C++ functions. When this subclause mentions a C entity, the reference also applies to the corresponding entity in C++.

*Static Semantics*

3 The library package Interfaces.C has the following declaration:

```

4 package Interfaces.C is
5 pragma Pure(C);
6 -- Declarations based on C's <limits.h>
7 CHAR_BIT : constant := implementation-defined; -- typically 8
8 SCHAR_MIN : constant := implementation-defined; -- typically -128
9 SCHAR_MAX : constant := implementation-defined; -- typically 127
10 UCHAR_MAX : constant := implementation-defined; -- typically 255
11
12 -- Signed and Unsigned Integers
13 type int is range implementation-defined;
14 type short is range implementation-defined;
15 type long is range implementation-defined;
16
17 type signed_char is range SCHAR_MIN .. SCHAR_MAX;
18 for signed_char'Size use CHAR_BIT;
19
20 type unsigned is mod implementation-defined;
21 type unsigned_short is mod implementation-defined;
22 type unsigned_long is mod implementation-defined;
23
24 type unsigned_char is mod (UCHAR_MAX+1);
25 for unsigned_char'Size use CHAR_BIT;
26
27 subtype plain_char is implementation-defined;
28
29 type ptrdiff_t is range implementation-defined;

```

```

type size_t is mod implementation-defined; 13
-- Floating Point 14
type C_float is digits implementation-defined; 15
type double is digits implementation-defined; 16
type long_double is digits implementation-defined; 17
-- Characters and Strings 18
type char is <implementation-defined character type>; 19
{8652/0060} {AI95-00037-01} nul : constant char := implementation-defined; 20/1
function To_C (Item : in Character) return char; 21
function To_Ada (Item : in char) return Character; 22
{AI05-0229-1} {AI05-0269-1} type char_array is array (size_t range <>) of 23/3

41 end Interfaces.C;
41.a.1/2 Implementation defined: The definitions of certain types and constants in Interfaces.C.
42 Each of the types declared in Interfaces.C is C-compatible.
43/2 {AI95-00285-01} The types int, short, long, unsigned, ptrdiff_t, size_t, double, char, wchar_t, char16_t,
and char32_t correspond respectively to the C types having the same names. The types signed_char,
unsigned_short, unsigned_long, unsigned_char, C_float, and long_double correspond respectively to the
C types signed char, unsigned short, unsigned long, unsigned char, float, and long double.
43.a/2 Discussion: The C types wchar_t and char16_t seem to be the same. However, wchar_t has an implementation-defined
size, whereas char16_t is guaranteed to be an unsigned type of at least 16 bits. Also, char16_t and char32_t are

```

encouraged to have UTF-16 and UTF-32 representations; that means that they are not directly the same as the Ada types, which most likely don't use any UTF encoding.

The type of the subtype `plain_char` is either `signed_char` or `unsigned_char`, depending on the C implementation. 44

```
function To_C (Item : in Character) return char; 45
function To_Ada (Item : in char) return Character;
```

The functions `To_C` and `To_Ada` map between the Ada type `Character` and the C type `char`. 46

**Implementation Note:** {8652/0114} {AI95-00038-01} The `To_C` and `To_Ada` functions map between corresponding characters, not necessarily between characters with the same internal representation. Corresponding characters are characters defined by the same enumeration literal, if such exist; otherwise, the correspondence is unspecified. 46.a.1/1

The following definition is equivalent to the above summary: 46.a.2/1

```
To_C (Latin_1_Char) = char'Value(Character'Image(Latin_1_Char)) 46.a.3/1
provided that char'Value does not raise an exception; otherwise the result is unspecified.
```

```
To_Ada (Native_C_Char) = Character'Value(char'Image(Native_C_Char)) 46.a.4/1
provided that Character'Value does not raise an exception; otherwise the result is unspecified.
```

```
function Is_Nul_Terminated (Item : in char_array) return Boolean; 47
```

The result of `Is_Nul_Terminated` is `True` if `Item` contains `nul`, and is `False` otherwise. 48

```
function To_C (Item : in String; Append_Nul : in Boolean := True) 49
return char_array;
```

```
function To_Ada (Item : in char_array; Trim_Nul : in Boolean := True)
return String;
```

{AI95-00258-01} The result of `To_C` is a `char_array` value of length `Item'Length` (if `Append_Nul` is `False`) or `Item'Length+1` (if `Append_Nul` is `True`). The lower bound is 0. For each component `Item(I)`, the corresponding component in the result is `To_C` applied to `Item(I)`. The value `nul` is appended if `Append_Nul` is `True`. If `Append_Nul` is `False` and `Item'Length` is 0, then `To_C` propagates `Constraint_Error`. 50/2

The result of `To_Ada` is a `String` whose length is `Item'Length` (if `Trim_Nul` is `False`) or the length of the slice of `Item` preceding the first `nul` (if `Trim_Nul` is `True`). The lower bound of the result is 1. If `Trim_Nul` is `False`, then for each component `Item(I)` the corresponding component in the result is `To_Ada` applied to `Item(I)`. If `Trim_Nul` is `True`, then for each component `Item(I)` before the first `nul` the corresponding component in the result is `To_Ada` applied to `Item(I)`. The function propagates `Terminator_Error` if `Trim_Nul` is `True` and `Item` does not contain `nul`. 51

```
procedure To_C (Item : in String; 52
 Target : out char_array;
 Count : out size_t;
 Append_Nul : in Boolean := True);
```

```
procedure To_Ada (Item : in char_array;
 Target : out String;
 Count : out Natural;
 Trim_Nul : in Boolean := True);
```

For procedure `To_C`, each element of `Item` is converted (via the `To_C` function) to a `char`, which is assigned to the corresponding element of `Target`. If `Append_Nul` is `True`, `nul` is then assigned to the next element of `Target`. In either case, `Count` is set to the number of `Target` elements assigned. If `Target` is not long enough, `Constraint_Error` is propagated. 53

For procedure `To_Ada`, each element of `Item` (if `Trim_Nul` is `False`) or each element of `Item` preceding the first `nul` (if `Trim_Nul` is `True`) is converted (via the `To_Ada` function) to a `Character`, which is assigned to the corresponding element of `Target`. `Count` is set to the number 54

of Target elements assigned. If Target is not long enough, Constraint\_Error is propagated. If Trim\_Nul is True and Item does not contain nul, then Terminator\_Error is propagated.

55 **function** Is\_Nul\_Terminated (Item : **in** wchar\_array) **return** Boolean;

56 The result of Is\_Nul\_Terminated is True if Item contains wide\_nul, and is False otherwise.

57 **function** To\_C (Item : **in** Wide\_Character) **return** wchar\_t;  
**function** To\_Ada (Item : **in** wchar\_t ) **return** Wide\_Character;

58 To\_C and To\_Ada provide the mappings between the Ada and C wide character types.

59 **function** To\_C (Item : **in** Wide\_String;  
Append\_Nul : **in** Boolean := True)  
**return** wchar\_array;

**function** To\_Ada (Item : **in** wchar\_array;  
Trim\_Nul : **in** Boolean := True)  
**return** Wide\_String;

**procedure** To\_C (Item : **in** Wide\_String;  
Target : **out** wchar\_array;  
Count : **out** size\_t;  
Append\_Nul : **in** Boolean := True);

**procedure** To\_Ada (Item : **in** wchar\_array;  
Target : **out** Wide\_String;  
Count : **out** Natural;  
Trim\_Nul : **in** Boolean := True);

60 The To\_C and To\_Ada subprograms that convert between Wide\_String and wchar\_array have analogous effects to the To\_C and To\_Ada subprograms that convert between String and char\_array, except that wide\_nul is used instead of nul.

60.1/2 **function** Is\_Nul\_Terminated (Item : **in** char16\_array) **return** Boolean;

60.2/2 {AI95-00285-01} The result of Is\_Nul\_Terminated is True if Item contains char16\_nul, and is False otherwise.

60.3/2 **function** To\_C (Item : **in** Wide\_Character) **return** char16\_t;  
**function** To\_Ada (Item : **in** char16\_t ) **return** Wide\_Character;

60.4/2 {AI95-00285-01} To\_C and To\_Ada provide mappings between the Ada and C 16-bit character types.

60.5/2 **function** To\_C (Item : **in** Wide\_String;  
Append\_Nul : **in** Boolean := True)  
**return** char16\_array;

**function** To\_Ada (Item : **in** char16\_array;  
Trim\_Nul : **in** Boolean := True)  
**return** Wide\_String;

**procedure** To\_C (Item : **in** Wide\_String;  
Target : **out** char16\_array;  
Count : **out** size\_t;  
Append\_Nul : **in** Boolean := True);

**procedure** To\_Ada (Item : **in** char16\_array;  
Target : **out** Wide\_String;  
Count : **out** Natural;  
Trim\_Nul : **in** Boolean := True);

60.6/2 {AI95-00285-01} The To\_C and To\_Ada subprograms that convert between Wide\_String and char16\_array have analogous effects to the To\_C and To\_Ada subprograms that convert between String and char\_array, except that char16\_nul is used instead of nul.

- function** Is\_Nul\_Terminated (Item : in char32\_array) **return** Boolean; 60.7/2  
 {AI95-00285-01} The result of Is\_Nul\_Terminated is True if Item contains char16\_nul, and is False otherwise. 60.8/2
- function** To\_C (Item : in Wide\_Wide\_Character) **return** char32\_t; 60.9/2  
**function** To\_Ada (Item : in char32\_t) **return** Wide\_Wide\_Character;  
 {AI95-00285-01} To\_C and To\_Ada provide mappings between the Ada and C 32-bit character types. 60.10/2
- function** To\_C (Item : in Wide\_Wide\_String; Append\_Nul : in Boolean := True) **return** char32\_array; 60.11/2
- function** To\_Ada (Item : in char32\_array; Trim\_Nul : in Boolean := True) **return** Wide\_Wide\_String;
- procedure** To\_C (Item : in Wide\_Wide\_String; Target : out char32\_array; Count : out size\_t; Append\_Nul : in Boolean := True);
- procedure** To\_Ada (Item : in char32\_array; Target : out Wide\_Wide\_String; Count : out Natural; Trim\_Nul : in Boolean := True);
- {AI95-00285-01} The To\_C and To\_Ada subprograms that convert between Wide\_Wide\_String and char32\_array have analogous effects to the To\_C and To\_Ada subprograms that convert between String and char\_array, except that char32\_nul is used instead of nul. 60.12/2
- Discussion:** The Interfaces.C package provides an implementation-defined character type, char, designed to model the C run-time character set, and mappings between the types char and Character. 60.a
- One application of the C interface package is to compose a C string and pass it to a C function. One way to do this is for the programmer to declare an object that will hold the C array, and then pass this array to the C function. This is realized via the type char\_array: 60.b
- ```
type char_array is array (size_t range <>) of Char;
```
- 60.c
- The programmer can declare an Ada String, convert it to a char_array, and pass the char_array as actual parameter to the C function that is expecting a char *. 60.d
- An alternative approach is for the programmer to obtain a C char pointer from an Ada String (or from a char_array) by invoking an allocation function. The package Interfaces.C.Strings (see below) supplies the needed facilities, including a private type chars_ptr that corresponds to C's char *, and two allocation functions. To avoid storage leakage, a Free procedure releases the storage that was allocated by one of these allocate functions. 60.e
- It is typical for a C function that deals with strings to adopt the convention that the string is delimited by a nul char. The C interface packages support this convention. A constant nul of type Char is declared, and the function Value(Chars_Ptr) in Interfaces.C.Strings returns a char_array up to and including the first nul in the array that the chars_ptr points to. The Allocate_Chars function allocates an array that is nul terminated. 60.f
- Some C functions that deal with strings take an explicit length as a parameter, thus allowing strings to be passed that contain nul as a data element. Other C functions take an explicit length that is an upper bound: the prefix of the string up to the char before nul, or the prefix of the given length, is used by the function, whichever is shorter. The C Interface packages support calling such functions. 60.g
- {8652/0059} {AI95-00131-01} {AI05-0229-1} The Convention aspect with *convention_identifier* C_Pass_By_Copy shall only be specified for a type. 60.13/3
- {8652/0059} {AI95-00131-01} {AI95-00216-01} The eligibility rules in B.1 do not apply to convention C_Pass_By_Copy. Instead, a type T is eligible for convention C_Pass_By_Copy if T is an unchecked union type or if T is a record type that has no discriminants and that only has components with statically constrained subtypes, and each component is C-compatible. 60.14/2

- 60.15/3 {8652/0059} {AI95-00131-01} {AI05-0264-1} If a type is C_Pass_By_Copy-compatible, then it is also C-compatible.

Implementation Requirements

- 61/3 {8652/0059} {AI95-00131-01} {AI05-0229-1} An implementation shall support specifying aspect Convention with a C *convention_identifier* for a C-eligible type (see B.1). An implementation shall support specifying aspect Convention with a C_Pass_By_Copy *convention_identifier* for a C_Pass_By_Copy-eligible type.

Implementation Permissions

- 62 An implementation may provide additional declarations in the C interface packages.
- 62.1/3 {AI05-0002-1} {AI05-0229-1} An implementation need not support specifying the Convention aspect with *convention_identifier* C in the following cases:
- 62.2/3 • {AI05-0248-1} for a subprogram that has a parameter of an unconstrained array subtype, unless the Import aspect has the value True for the subprogram;
- 62.3/3 • for a function with an unconstrained array result subtype;
- 62.4/3 • for an object whose nominal subtype is an unconstrained array subtype.
- 62.a/3 **Implementation Note:** {AI05-0002-1} These rules ensure that an implementation never needs to create bounds for an unconstrained array that originates in C (and thus does not have bounds). An implementation can do so if it wishes, of course. Note that these permissions do not extend to passing an unconstrained array as a parameter to a C function; in this case, the bounds can simply be dropped and thus support is required.

Implementation Advice

- 62.5/3 {8652/0060} {AI95-00037-01} {AI95-00285-01} The constants nul, wide_nul, char16_nul, and char32_nul should have a representation of zero.
- 62.b/2 **Implementation Advice:** The constants nul, wide_nul, char16_nul, and char32_nul in package Interfaces.C should have a representation of zero.
- 63 An implementation should support the following interface correspondences between Ada and C.
- 64 • An Ada procedure corresponds to a void-returning C function.
- 64.a **Discussion:** The programmer can also choose an Ada procedure when the C function returns an int that is to be discarded.
- 65 • An Ada function corresponds to a non-void C function.
- 66 • An Ada **in** scalar parameter is passed as a scalar argument to a C function.
- 67 • An Ada **in** parameter of an access-to-object type with designated type T is passed as a t* argument to a C function, where t is the C type corresponding to the Ada type T.
- 68 • An Ada **access** T parameter, or an Ada **out** or **in out** parameter of an elementary type T, is passed as a t* argument to a C function, where t is the C type corresponding to the Ada type T. In the case of an elementary **out** or **in out** parameter, a pointer to a temporary copy is used to preserve by-copy semantics.
- 68.1/2 • {8652/0059} {AI95-00131-01} {AI95-00343-01} An Ada parameter of a (record) type T of convention C_Pass_By_Copy, of mode **in**, is passed as a t argument to a C function, where t is the C struct corresponding to the Ada type T.
- 69/2 • {8652/0059} {AI95-00131-01} {AI95-00343-01} An Ada parameter of a record type T, of any mode, other than an **in** parameter of a type of convention C_Pass_By_Copy, is passed as a t* argument to a C function, where t is the C struct corresponding to the Ada type T.

- An Ada parameter of an array type with component type T, of any mode, is passed as a t* argument to a C function, where t is the C type corresponding to the Ada type T. 70
- An Ada parameter of an access-to-subprogram type is passed as a pointer to a C function whose prototype corresponds to the designated subprogram's specification. 71
- {AI05-0002-1} An Ada parameter of a private type is passed as specified for the full view of the type. 71.1/3
- {AI05-0002-1} The rules of correspondence given above for parameters of mode **in** also apply to the return object of a function. 71.2/3

This paragraph was deleted. {AI95-00337-01} {AI05-0002-1} 71.3/3

Implementation Advice: If C interfacing is supported, the interface correspondences between Ada and C should be supported. 71.a/2

NOTES

6 Values of type `char_array` are not implicitly terminated with `nul`. If a `char_array` is to be passed as a parameter to an imported C function requiring `nul` termination, it is the programmer's responsibility to obtain this effect. 72

7 To obtain the effect of C's `sizeof(item_type)`, where `Item_Type` is the corresponding Ada type, evaluate the expression: `size_t(Item_Type'Size/CHAR_BIT)`. 73

This paragraph was deleted. {AI95-00216-01} 74/2

8 A C function that takes a variable number of arguments can correspond to several Ada subprograms, taking various specific numbers and types of parameters. 75

Examples

Example of using the Interfaces.C package: 76

--Calling the C Library Function strcpy 77

```
with Interfaces.C;
procedure Test is
  package C renames Interfaces.C;
  use type C.char_array;
  -- Call <string.h>strcpy:
  -- C definition of strcpy: char *strcpy(char *s1, const char *s2);
  -- This function copies the string pointed to by s2 (including the terminating null character)
  -- into the array pointed to by s1. If copying takes place between objects that overlap,
  -- the behavior is undefined. The strcpy function returns the value of s1.
  {AI05-0229-1} -- Note: since the C function's return value is of no interest, the Ada interface is a procedure
  procedure Strcpy (Target : out C.char_array;
                   Source : in C.char_array)
    with Import => True, Convention => C, External_Name => "strcpy";
```

This paragraph was deleted. {AI05-0229-1} 79/3

```
Chars1 : C.char_array(1..20); 80
```

```
Chars2 : C.char_array(1..20);
```

```
begin 81
```

```
  Chars2(1..6) := "qwert" & C.nul;
```

```
  Strcpy(Chars1, Chars2); 82
```

-- Now Chars1(1..6) = "qwert" & C.Nul 83

```
end Test; 84
```

Incompatibilities With Ada 95

{AI95-00285-01} {AI05-0005-1} Types `char16_t` and `char32_t` and their related types and operations are added to `Interfaces.C`. If `Interfaces.C` is referenced in a `use_clause`, and an entity *E* with the same `defining_identifier` as a new entity in `Interfaces.C` is defined in a package that is also referenced in a `use_clause`, the entity *E* may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur. 84.a/3

Extensions to Ada 95

{8652/0059} {AI95-00131-01} **Corrigendum:** Convention `C_Pass_By_Copy` is new. 84.b/2

Wording Changes from Ada 95

- 84.c/2 {8652/0060} {AI95-00037-01} **Corrigendum:** Clarified the intent for Nul and Wide_Nul.
- 84.d/2 {AI95-00216-01} Specified that an unchecked union type (see B.3.3) is eligible for convention C_Pass_By_Copy.
- 84.e/2 {AI95-00258-01} Specified what happens if the To_C function tries to return a null string.
- 84.f/2 {AI95-00337-01} Clarified that the interface correspondences also apply to private types whose full types have the specified characteristics.
- 84.g/2 {AI95-00343-01} Clarified that a type must have convention C_Pass_By_Copy in order to be passed by copy (not just a type that could have that convention).
- 84.h/2 {AI95-00376-01} Added wording to make it clear that these facilities can also be used with C++.

Incompatibilities With Ada 2005

- 84.i/3 {AI05-0002-1} **Correction:** Added a definition of correspondences for function results. Also added wording to make it clear that we do not expect the implementation to conjure bounds for unconstrained arrays out of thin air. These changes allow (but don't require) compilers to reject unreasonable uses of array types. Such uses probably didn't work anyway (and probably were rejected, no matter what the language definition said), so little existing code should be impacted.

B.3.1 The Package Interfaces.C.Strings

- 1/3 {AI05-0229-1} The package Interfaces.C.Strings declares types and subprograms allowing an Ada program to allocate, reference, update, and free C-style strings. In particular, the private type chars_ptr corresponds to a common use of “char *” in C programs, and an object of this type can be passed to a subprogram to which **with** Import => True, Convention => C has been specified, and for which “char *” is the type of the argument of the C function.

Static Semantics

2 The library package Interfaces.C.Strings has the following declaration:

```

3  package Interfaces.C.Strings is
4      pragma Preelaborate(Strings);
5
6      type char_array_access is access all char_array;
7
8      {AI95-00161-01} type chars_ptr is private;
9      pragma Preelaborable_Initialization(chars_ptr);
10
11     {AI95-00276-01} type chars_ptr_array is array (size_t range <>) of aliased
12     chars_ptr;
13
14     Null_Ptr : constant chars_ptr;
15
16     function To_Chars_Ptr (Item      : in char_array_access;
17                          Nul_Check : in Boolean := False)
18     return chars_ptr;
19
20     function New_Char_Array (Chars   : in char_array) return chars_ptr;
21
22     function New_String (Str : in String) return chars_ptr;
23
24     procedure Free (Item : in out chars_ptr);
25
26     Dereference_Error : exception;
27
28     function Value (Item : in chars_ptr) return char_array;
29
30     function Value (Item : in chars_ptr; Length : in size_t)
31     return char_array;
32
33     function Value (Item : in chars_ptr) return String;
34
35     function Value (Item : in chars_ptr; Length : in size_t)
36     return String;
37
38     function Strlen (Item : in chars_ptr) return size_t;
```

```

procedure Update (Item   : in chars_ptr;
                  Offset : in size_t;
                  Chars   : in char_array;
                  Check   : in Boolean := True);

```

18

```

procedure Update (Item   : in chars_ptr;
                  Offset : in size_t;
                  Str     : in String;
                  Check   : in Boolean := True);

```

19

```

Update_Error : exception;

```

20

```

private
... -- not specified by the language
end Interfaces.C.Strings;

```

21

Discussion: The string manipulation types and subprograms appear in a child of Interfaces.C versus being there directly, since it is useful to have Interfaces.C specified as `pragma Pure`.

21.a

Differently named functions `New_String` and `New_Char_Array` are declared, since if there were a single overloaded function a call with a string literal as actual parameter would be ambiguous.

21.b

The type `chars_ptr` is C-compatible and corresponds to the use of C's “char *” for a pointer to the first char in a char array terminated by `nul`. When an object of type `chars_ptr` is declared, its value is by default set to `Null_Ptr`, unless the object is imported (see B.1).

22

Discussion: The type `char_array_access` is not necessarily C-compatible, since an object of this type may carry “dope” information. The programmer should convert from `char_array_access` to `chars_ptr` for objects imported from, exported to, or passed to C.

22.a

```

function To_Chars_Ptr (Item       : in char_array_access;
                      Nul_Check  : in Boolean := False)
return chars_ptr;

```

23

{8652/0061} {AI95-00140-01} {AI05-0264-1} If `Item` is `null`, then `To_Chars_Ptr` returns `Null_Ptr`. If `Item` is not `null`, `Nul_Check` is `True`, and `Item.all` does not contain `nul`, then the function propagates `Terminator_Error`; otherwise, `To_Chars_Ptr` performs a pointer conversion with no allocation of memory.

24/3

```

function New_Char_Array (Chars   : in char_array) return chars_ptr;

```

25

This function returns a pointer to an allocated object initialized to `Chars(Chars'First .. Index) & nul`, where

26

- `Index = Chars'Last` if `Chars` does not contain `nul`, or
- `Index` is the smallest `size_t` value `I` such that `Chars(I+1) = nul`.

27

28

`Storage_Error` is propagated if the allocation fails.

28.1

```

function New_String (Str : in String) return chars_ptr;

```

29

This function is equivalent to `New_Char_Array(To_C(Str))`.

30

```

procedure Free (Item : in out chars_ptr);

```

31

If `Item` is `Null_Ptr`, then `Free` has no effect. Otherwise, `Free` releases the storage occupied by `Value(Item)`, and resets `Item` to `Null_Ptr`.

32

```

function Value (Item : in chars_ptr) return char_array;

```

33

{AI05-0264-1} If `Item = Null_Ptr`, then `Value` propagates `Dereference_Error`. Otherwise, `Value` returns the prefix of the array of chars pointed to by `Item`, up to and including the first `nul`. The lower bound of the result is 0. If `Item` does not point to a `nul`-terminated string, then execution of `Value` is erroneous.

34/3

```

35  function Value (Item : in chars_ptr; Length : in size_t)
      return char_array;
36/3  {8652/0062} {AI95-00139-01} {AI05-0264-1} If Item = Null_Ptr, then Value propagates
      Dereference_Error. Otherwise, Value returns the shorter of two arrays, either the first Length
      chars pointed to by Item, or Value(Item). The lower bound of the result is 0. If Length is 0, then
      Value propagates Constraint_Error.
36.a  Ramification: Value(New_Char_Array(Chars)) = Chars if Chars does not contain nul; else Value(New_Char_Array(
      Chars)) is the prefix of Chars up to and including the first nul.
37  function Value (Item : in chars_ptr) return String;
38  Equivalent to To_Ada(Value(Item), Trim_Nul=>True).
39  function Value (Item : in chars_ptr; Length : in size_t)
      return String;
40/1  {8652/0063} {AI95-00177-01} Equivalent to To_Ada(Value(Item, Length) & nul,
      Trim_Nul=>True).
41  function Strlen (Item : in chars_ptr) return size_t;
42  Returns Val'Length-1 where Val = Value(Item); propagates Dereference_Error if Item =
      Null_Ptr.
42.a  Ramification: Strlen returns the number of chars in the array pointed to by Item, up to and including the char
      immediately before the first nul.
42.b  Strlen has the same possibility for erroneous execution as Value, in cases where the string has not been nul-terminated.
42.c  Strlen has the effect of C's strlen function.
43  procedure Update (Item : in chars_ptr;
                    Offset : in size_t;
                    Chars : in char_array;
                    Check : Boolean := True);
44/1  {8652/0064} {AI95-00039-01} If Item = Null_Ptr, then Update propagates Dereference_Error.
      Otherwise, this procedure updates the value pointed to by Item, starting at position Offset, using
      Chars as the data to be copied into the array. Overwriting the nul terminator, and skipping with
      the Offset past the nul terminator, are both prevented if Check is True, as follows:
45  • Let N = Strlen(Item). If Check is True, then:
46  • If Offset+Chars'Length>N, propagate Update_Error.
47  • Otherwise, overwrite the data in the array pointed to by Item, starting at the char at
      position Offset, with the data in Chars.
48  • If Check is False, then processing is as above, but with no check that
      Offset+Chars'Length>N.
48.a  Ramification: If Chars contains nul, Update's effect may be to “shorten” the pointed-to char array.
49  procedure Update (Item : in chars_ptr;
                    Offset : in size_t;
                    Str : in String;
                    Check : in Boolean := True);
50/2  {AI95-00242-01} Equivalent to Update(Item, Offset, To_C(Str, Append_Nul => False), Check).
50.a/2  Discussion: {AI95-00242-01} To truncate the Item to the length of Str, use Update(Item, Offset, To_C(Str), Check)
      instead of Update(Item, Offset, Str, Check). Note that when truncating Item, Item must be longer than Str.

```

Erroneous Execution

Execution of any of the following is erroneous if the Item parameter is not null_ptr and Item does not point to a nul-terminated array of chars. 51

- a Value function not taking a Length parameter, 52
- the Free procedure, 53
- the Strlen function. 54

Execution of Free(X) is also erroneous if the chars_ptr X was not returned by New_Char_Array or New_String. 55

Reading or updating a freed char_array is erroneous. 56

Execution of Update is erroneous if Check is False and a call with Check equal to True would have propagated Update_Error. 57

NOTES

9 New_Char_Array and New_String might be implemented either through the allocation function from the C environment (“malloc”) or through Ada dynamic memory allocation (“new”). The key points are 58

- the returned value (a chars_ptr) is represented as a C “char*” so that it may be passed to C functions; 59
- the allocated object should be freed by the programmer via a call of Free, not by a called C function. 60

Inconsistencies With Ada 95

{AI95-00242-01} **Amendment Correction:** Update for a String parameter is now defined to not add a nul character. It did add a nul in Ada 95. This means that programs that used this behavior of Update to truncate a string will no longer work (the string will not be truncated). This change makes Update for a string consistent with Update for a char_array (no implicit nul is added to the end of a char_array). 60.a/2

Extensions to Ada 95

{AI95-00161-01} **Amendment Correction:** Added pragma Preelaborable_Initialization to type chars_ptr, so that it can be used in preelaborated units. 60.b/2

{AI95-00276-01} **Amendment Correction:** The components of chars_ptr_array are aliased so that it can be used to instantiate Interfaces.C.Pointers (that is its intended purpose, which is otherwise mysterious as it has no operations). 60.c/2

Wording Changes from Ada 95

{8652/0061} {AI95-00140-01} **Corrigendum:** Fixed the missing semantics of To_Char_Ptr when Nul_Check is False. 60.d/2

{8652/0062} {AI95-00139-01} **Corrigendum:** Fixed the missing semantics of Value when the Length is 0. 60.e/2

{8652/0063} {AI95-00177-01} **Corrigendum:** Corrected the definition of Value to avoid raising Terminator_Error. 60.f/2

{8652/0064} {AI95-00039-01} **Corrigendum:** Fixed the missing semantics of Update when Item is Null_Ptr. 60.g/2

B.3.2 The Generic Package Interfaces.C.Pointers

The generic package Interfaces.C.Pointers allows the Ada programmer to perform C-style operations on pointers. It includes an access type Pointer, Value functions that dereference a Pointer and deliver the designated array, several pointer arithmetic operations, and “copy” procedures that copy the contents of a source pointer into the array designated by a destination pointer. As in C, it treats an object Ptr of type Pointer as a pointer to the first element of an array, so that for example, adding 1 to Ptr yields a pointer to the second element of the array. 1

The generic allows two styles of usage: one in which the array is terminated by a special terminator element; and another in which the programmer needs to keep track of the length. 2

Static Semantics

The generic library package Interfaces.C.Pointers has the following declaration: 3

```

4   generic
    type Index is (<>);
    type Element is private;
    type Element_Array is array (Index range <>) of aliased Element;
    Default_Terminator : Element;
  package Interfaces.C.Pointers is
    pragma Preelaborate(Pointers);
5   type Pointer is access all Element;
6   function Value(Ref          : in Pointer;
                  Terminator : in Element := Default_Terminator)
    return Element_Array;
7   function Value(Ref          : in Pointer;
                  Length      : in ptrdiff_t)
    return Element_Array;
8   Pointer_Error : exception;
9   -- C-style Pointer arithmetic
10/3 {AI05-0229-1} function "+" (Left : in Pointer;   Right : in ptrdiff_t) return
Pointer
    with Convention => Intrinsic;
    function "+" (Left : in ptrdiff_t; Right : in Pointer) return Pointer
    with Convention => Intrinsic;
    function "-" (Left : in Pointer;   Right : in ptrdiff_t) return Pointer
    with Convention => Intrinsic;
    function "-" (Left : in Pointer;   Right : in Pointer) return ptrdiff_t
    with Convention => Intrinsic;
11/3 {AI05-0229-1} procedure Increment (Ref : in out Pointer)
    with Convention => Intrinsic;
    procedure Decrement (Ref : in out Pointer)
    with Convention => Intrinsic;
12/3 This paragraph was deleted. {AI05-0229-1}
13   function Virtual_Length (Ref          : in Pointer;
                            Terminator : in Element := Default_Terminator)
    return ptrdiff_t;
14   procedure Copy_Terminated_Array
    (Source      : in Pointer;
     Target      : in Pointer;
     Limit       : in ptrdiff_t := ptrdiff_t'Last;
     Terminator  : in Element := Default_Terminator);
15   procedure Copy_Array (Source : in Pointer;
                          Target  : in Pointer;
                          Length  : in ptrdiff_t);
16   end Interfaces.C.Pointers;

```

The type `Pointer` is C-compatible and corresponds to one use of C's "Element *". An object of type `Pointer` is interpreted as a pointer to the initial `Element` in an `Element_Array`. Two styles are supported:

- Explicit termination of an array value with `Default_Terminator` (a special terminator value);
- Programmer-managed length, with `Default_Terminator` treated simply as a data element.

```

20   function Value(Ref          : in Pointer;
                  Terminator : in Element := Default_Terminator)
    return Element_Array;

```

This function returns an `Element_Array` whose value is the array pointed to by `Ref`, up to and including the first `Terminator`; the lower bound of the array is `Index'First`. `Interfaces.C.Strings.Dereference_Error` is propagated if `Ref` is `null`.

```
function Value(Ref      : in Pointer;
              Length : in ptrdiff_t)
return Element_Array;

```

This function returns an `Element_Array` comprising the first `Length` elements pointed to by `Ref`. The exception `Interfaces.C.Strings.Dereference_Error` is propagated if `Ref` is **null**.

The "+" and "-" functions perform arithmetic on `Pointer` values, based on the `Size` of the array elements. In each of these functions, `Pointer_Error` is propagated if a `Pointer` parameter is **null**.

```
procedure Increment (Ref : in out Pointer);

```

Equivalent to `Ref := Ref+1`.

```
procedure Decrement (Ref : in out Pointer);

```

Equivalent to `Ref := Ref-1`.

```
function Virtual_Length (Ref          : in Pointer;
                       Terminator : in Element := Default_Terminator)
return ptrdiff_t;

```

Returns the number of `Elements`, up to the one just before the first `Terminator`, in `Value(Ref, Terminator)`.

```
procedure Copy_Terminated_Array
(Source      : in Pointer;
 Target     : in Pointer;
 Limit      : in ptrdiff_t := ptrdiff_t'Last;
 Terminator : in Element := Default_Terminator);

```

This procedure copies `Value(Source, Terminator)` into the array pointed to by `Target`; it stops either after `Terminator` has been copied, or the number of elements copied is `Limit`, whichever occurs first. `Dereference_Error` is propagated if either `Source` or `Target` is **null**.

Ramification: It is the programmer's responsibility to ensure that elements are not copied beyond the logical length of the target array.

Implementation Note: The implementation has to take care to check the `Limit` first.

```
procedure Copy_Array (Source : in Pointer;
                    Target  : in Pointer;
                    Length  : in ptrdiff_t);

```

This procedure copies the first `Length` elements from the array pointed to by `Source`, into the array pointed to by `Target`. `Dereference_Error` is propagated if either `Source` or `Target` is **null**.

Erroneous Execution

It is erroneous to dereference a `Pointer` that does not designate an aliased `Element`.

Discussion: Such a `Pointer` could arise via "+", "-", `Increment`, or `Decrement`.

Execution of `Value(Ref, Terminator)` is erroneous if `Ref` does not designate an aliased `Element` in an `Element_Array` terminated by `Terminator`.

Execution of `Value(Ref, Length)` is erroneous if `Ref` does not designate an aliased `Element` in an `Element_Array` containing at least `Length` `Elements` between the designated `Element` and the end of the array, inclusive.

Execution of `Virtual_Length(Ref, Terminator)` is erroneous if `Ref` does not designate an aliased `Element` in an `Element_Array` terminated by `Terminator`.

Execution of `Copy_Terminated_Array(Source, Target, Limit, Terminator)` is erroneous in either of the following situations:

- 40 • Execution of both Value(Source, Terminator) and Value(Source, Limit) are erroneous, or
- 41 • Copying writes past the end of the array containing the Element designated by Target.

42 Execution of Copy_Array(Source, Target, Length) is erroneous if either Value(Source, Length) is erroneous, or copying writes past the end of the array containing the Element designated by Target.

NOTES

43 10 To compose a Pointer from an Element_Array, use 'Access on the first element. For example (assuming appropriate instantiations):

```
44     Some_Array   : Element_Array(0..5) ;
     Some_Pointer : Pointer := Some_Array(0)'Access;
```

Examples

45 *Example of Interfaces.C.Pointers:*

```
46     with Interfaces.C.Pointers;
     with Interfaces.C.Strings;
     procedure Test_Pointers is
       package C renames Interfaces.C;
       package Char_Ptrs is
         new C.Pointers (Index           => C.size_t,
                        Element         => C.char,
                        Element_Array    => C.char_array,
                        Default_Terminator => C.nul);

47     use type Char_Ptrs.Pointer;
     subtype Char_Star is Char_Ptrs.Pointer;

48     procedure Strcpy (Target_Ptr, Source_Ptr : Char_Star) is
       Target_Temp_Ptr : Char_Star := Target_Ptr;
       Source_Temp_Ptr : Char_Star := Source_Ptr;
       Element : C.char;
     begin
       if Target_Temp_Ptr = null or Source_Temp_Ptr = null then
         raise C.Strings.Dereference_Error;
       end if;
49/1   {8652/0065} {AI95-00142-01}     loop
         Element := Source_Temp_Ptr.all;
         Target_Temp_Ptr.all := Element;
         exit when C."=" (Element, C.nul);
         Char_Ptrs.Increment (Target_Temp_Ptr);
         Char_Ptrs.Increment (Source_Temp_Ptr);
       end loop;
     end Strcpy;
     begin
       ...
     end Test_Pointers;
```

B.3.3 Unchecked Union Types

1/3 {AI95-00216-01} {AI05-0229-1} {AI05-0269-1} [Specifying aspect Unchecked_Union to have the value True defines an interface correspondence between a given discriminated type and some C union. The aspect requires that the associated type shall be given a representation that allocates no space for its discriminant(s).]

Paragraphs 2 through 3 were moved to Annex J, “Obsolescent Features”.

Static Semantics

3.1/3 {AI05-0229-1} For a discriminated record type having a variant_part, the following language-defined representation aspect may be specified:

Unchecked_Union		3.2/3
	The type of aspect Unchecked_Union is Boolean. If directly specified, the <code>aspect_definition</code> shall be a static expression. If not specified (including by inheritance), the aspect is False.	
	Aspect Description for Unchecked_Union: Type is used to interface to a C union type.	3.a/3
	<i>Legality Rules</i>	
	<i>Paragraphs 4 and 5 were deleted.</i>	
{AI95-00216-01} {AI05-0229-1}	A type for which aspect Unchecked_Union is True is called an <i>unchecked union type</i> . A subtype of an unchecked union type is defined to be an <i>unchecked union subtype</i> . An object of an unchecked union type is defined to be an <i>unchecked union object</i> .	6/3
{AI95-00216-01}	All component subtypes of an unchecked union type shall be C-compatible.	7/2
{AI95-00216-01}	If a component subtype of an unchecked union type is subject to a per-object constraint, then the component subtype shall be an unchecked union subtype.	8/2
{AI95-00216-01} {AI05-0026-1}	Any name that denotes a discriminant of an object of an unchecked union type shall occur within the declarative region of the type, and shall not occur within a <code>record_representation_clause</code> .	9/3
{AI95-00216-01} {AI05-0026-1}	The type of a component declared in a <code>variant_part</code> of an unchecked union type shall not need finalization. In addition to the places where Legality Rules normally apply (see 12.3), this rule also applies in the private part of an instance of a generic unit. For an unchecked union type declared within the body of a generic unit, or within the body of any of its descendant library units, no part of the type of a component declared in a <code>variant_part</code> of the unchecked union type shall be of a formal private type or formal private extension declared within the formal part of the generic unit.	10/3
	Reason: {AI05-0026-1} The last part is a classic assume-the-worst rule that avoids dependence on the actuals in a generic body. We did not include this in the definition of “needs finalization” as it has a bad interaction with the use of that term for the <code>No_Nested_Finalization</code> restriction.	10.a/3
{AI95-00216-01}	The completion of an incomplete or private type declaration having a <code>known_discriminant_part</code> shall not be an unchecked union type.	11/2
{AI95-00216-01}	An unchecked union subtype shall only be passed as a generic actual parameter if the corresponding formal type has no known discriminants or is an unchecked union type.	12/2
	Ramification: This includes formal private types without a <code>known_discriminant_part</code> , formal derived types that do not inherit any discriminants (formal derived types do not have <code>known_discriminant_parts</code>), and formal derived types that are unchecked union types.	12.a/2

Static Semantics

{AI95-00216-01}	An unchecked union type is eligible for convention C.	13/2
{AI95-00216-01}	All objects of an unchecked union type have the same size.	14/2
{AI95-00216-01}	Discriminants of objects of an unchecked union type are of size zero.	15/2
{AI95-00216-01}	Any check which would require reading a discriminant of an unchecked union object is suppressed (see 11.5). These checks include:	16/2
	<ul style="list-style-type: none"> • The check performed when addressing a variant component (i.e., a component that was declared in a <code>variant_part</code>) of an unchecked union object that the object has this component (see 4.1.3). 	17/2
	<ul style="list-style-type: none"> • Any checks associated with a type or subtype conversion of a value of an unchecked union type (see 4.6). This includes, for example, the check associated with the implicit subtype conversion of an assignment statement. 	18/2

- 19/2 • The subtype membership check associated with the evaluation of a qualified expression (see 4.7) or an uninitialized allocator (see 4.8).

19.a/2 **Discussion:** If a suppressed check would have failed, execution is erroneous (see 11.5). An implementation is always allowed to make a suppressed check if it can somehow determine the discriminant value.

Dynamic Semantics

20/2 {AI95-00216-01} A view of an unchecked union object (including a type conversion or function call) has *inferable discriminants* if it has a constrained nominal subtype, unless the object is a component of an enclosing unchecked union object that is subject to a per-object constraint and the enclosing object lacks inferable discriminants.

21/2 {AI95-00216-01} An expression of an unchecked union type has inferable discriminants if it is either a name of an object with inferable discriminants or a qualified expression whose `subtype_mark` denotes a constrained subtype.

22/2 {AI95-00216-01} Program_Error is raised in the following cases:

- 23/2 • Evaluation of the predefined equality operator for an unchecked union type if either of the operands lacks inferable discriminants.
- 24/2 • Evaluation of the predefined equality operator for a type which has a subcomponent of an unchecked union type whose nominal subtype is unconstrained.
- 25/2 • Evaluation of a membership test if the `subtype_mark` denotes a constrained unchecked union subtype and the expression lacks inferable discriminants.
- 26/2 • Conversion from a derived unchecked union type to an unconstrained non-unchecked-union type if the operand of the conversion lacks inferable discriminants.
- 27/2 • Execution of the default implementation of the Write or Read attribute of an unchecked union type.
- 28/2 • Execution of the default implementation of the Output or Input attribute of an unchecked union type if the type lacks default discriminant values.

Paragraph 29 was deleted.

NOTES

30/2 11 {AI95-00216-01} The use of an unchecked union to obtain the effect of an unchecked conversion results in erroneous execution (see 11.5). Execution of the following example is erroneous even if `Float'Size = Integer'Size`:

```
31/3 {AI05-0229-1} type T (Flag : Boolean := False) is
    record
        case Flag is
            when False =>
                F1 : Float := 0.0;
            when True =>
                F2 : Integer := 0;
            end case;
        end record
    with Unchecked_Union;

32/2 X : T;
    Y : Integer := X.F2; -- erroneous
```

Extensions to Ada 95

32.a/2 {AI95-00216-01} Pragma Unchecked_Union is new.

Incompatibilities With Ada 2005

32.b/3 {AI05-0026-1} **Correction:** The use of discriminants on Unchecked_Union types is now illegal in `record_representation_clauses`, as it makes no sense to specify a position for something that is not supposed to exist. It is very unlikely that this change will have any impact on existing code.

Extensions to Ada 2005

{AI05-0229-1} Aspect Unchecked_Union is new; pragma Unchecked_Union is now obsolescent. 32.c/3

Wording Changes from Ada 2005

{AI05-0026-1} **Correction:** Revised the rules to use the “needs finalization” definition, and eliminated generic contract issues. 32.d/3

B.4 Interfacing with COBOL

{AI05-0229-1} The facilities relevant to interfacing with the COBOL language are the package Interfaces.COBOL and support for specifying the Convention aspect with *convention_identifier* COBOL. 1/3

The COBOL interface package supplies several sets of facilities: 2

- A set of types corresponding to the native COBOL types of the supported COBOL implementation (so-called “internal COBOL representations”), allowing Ada data to be passed as parameters to COBOL programs 3
- A set of types and constants reflecting external data representations such as might be found in files or databases, allowing COBOL-generated data to be read by an Ada program, and Ada-generated data to be read by COBOL programs 4
- A generic package for converting between an Ada decimal type value and either an internal or external COBOL representation 5

Static Semantics

The library package Interfaces.COBOL has the following declaration: 6

```

package Interfaces.COBOL is 7
  pragma Preelaborate(COBOL);
-- Types and operations for internal data representations 8
  type Floating is digits implementation-defined; 9
  type Long_Floating is digits implementation-defined;
  type Binary is range implementation-defined; 10
  type Long_Binary is range implementation-defined;
  Max_Digits_Binary : constant := implementation-defined; 11
  Max_Digits_Long_Binary : constant := implementation-defined;
{AI05-0229-1} type Decimal_Element is mod implementation-defined; 12/3
type Packed_Decimal is array (Positive range <>) of Decimal_Element
  with Pack;
  type COBOL_Character is implementation-defined character type; 13
  Ada_To_COBOL : array (Character) of COBOL_Character := implementation-defined; 14
  COBOL_To_Ada : array (COBOL_Character) of Character := implementation-defined; 15
{AI05-0229-1} type Alphanumeric is array (Positive range <>) of COBOL_Character 16/3
  with Pack;
  function To_COBOL (Item : in String) return Alphanumeric; 17
  function To_Ada (Item : in Alphanumeric) return String;
  procedure To_COBOL (Item : in String; 18
                    Target : out Alphanumeric;
                    Last : out Natural);
  procedure To_Ada (Item : in Alphanumeric; 19
                  Target : out String;
                  Last : out Natural);

50

Implementation defined: The types `Floating`, `Long_Floating`, `Binary`, `Long_Binary`, `Decimal_Element`, and `COBOL_Character`; and the initializations of the variables `Ada_To_COBOL` and `COBOL_To_Ada`, in `Interfaces.COBOL`.

50.a/1

Each of the types in `Interfaces.COBOL` is COBOL-compatible. 51

The types `Floating` and `Long_Floating` correspond to the native types in COBOL for data items with computational usage implemented by floating point. The types `Binary` and `Long_Binary` correspond to the native types in COBOL for data items with binary usage, or with computational usage implemented by binary. 52

`Max_Digits_Binary` is the largest number of decimal digits in a numeric value that is represented as `Binary`. `Max_Digits_Long_Binary` is the largest number of decimal digits in a numeric value that is represented as `Long_Binary`. 53

The type `Packed_Decimal` corresponds to COBOL's packed-decimal usage. 54

The type `COBOL_Character` defines the run-time character set used in the COBOL implementation. `Ada_To_COBOL` and `COBOL_To_Ada` are the mappings between the Ada and COBOL run-time character sets. 55

Reason: The character mappings are visible variables, since the user needs the ability to modify them at run time. 55.a

Type `Alphanumeric` corresponds to COBOL's alphanumeric data category. 56

Each of the functions `To_COBOL` and `To_Ada` converts its parameter based on the mappings `Ada_To_COBOL` and `COBOL_To_Ada`, respectively. The length of the result for each is the length of the parameter, and the lower bound of the result is 1. Each component of the result is obtained by applying the relevant mapping to the corresponding component of the parameter. 57

Each of the procedures `To_COBOL` and `To_Ada` copies converted elements from `Item` to `Target`, using the appropriate mapping (`Ada_To_COBOL` or `COBOL_To_Ada`, respectively). The index in `Target` of the last element assigned is returned in `Last` (0 if `Item` is a null array). If `Item'Length` exceeds `Target'Length`, `Constraint_Error` is propagated. 58

Type `Numeric` corresponds to COBOL's numeric data category with display usage. 59

The types `Display_Format`, `Binary_Format`, and `Packed_Format` are used in conversions between Ada decimal type values and COBOL internal or external data representations. The value of the constant `Native_Binary` is either `High_Order_First` or `Low_Order_First`, depending on the implementation. 60

```

function Valid (Item   : in Numeric;
                Format  : in Display_Format) return Boolean;

```

61

The function `Valid` checks that the `Item` parameter has a value consistent with the value of `Format`. If the value of `Format` is other than `Unsigned`, `Leading_Separate`, and `Trailing_Separate`, the effect is implementation defined. If `Format` does have one of these values, the following rules apply: 62

- `{8652/0066} {A195-00071-01} {A105-0264-1}` `Format=Unsigned`: if `Item` comprises one or more decimal digit characters, then `Valid` returns `True`, else it returns `False`. 63/3
- `{8652/0066} {A195-00071-01}` `Format=Leading_Separate`: if `Item` comprises a single occurrence of the plus or minus sign character, and then one or more decimal digit characters, then `Valid` returns `True`, else it returns `False`. 64/1

- 65/1 • {8652/0066} {AI95-00071-01} `Format=Trailing_Separate`: if `Item` comprises one or more decimal digit characters and finally a plus or minus sign character, then `Valid` returns `True`, else it returns `False`.
- 66 **function** `Length` (`Format` : **in** `Display_Format`) **return** `Natural`;
- 67 The `Length` function returns the minimal length of a `Numeric` value sufficient to hold any value of type `Num` when represented as `Format`.
- 68 **function** `To_Decimal` (`Item` : **in** `Numeric`;
 `Format` : **in** `Display_Format`) **return** `Num`;
- 69 Produces a value of type `Num` corresponding to `Item` as represented by `Format`. The number of digits after the assumed radix point in `Item` is `Num'Scale`. `Conversion_Error` is propagated if the value represented by `Item` is outside the range of `Num`.
- 69.a **Discussion:** There is no issue of truncation versus rounding, since the number of decimal places is established by `Num'Scale`.
- 70 **function** `To_Display` (`Item` : **in** `Num`;
 `Format` : **in** `Display_Format`) **return** `Numeric`;
- 71/1 {8652/0067} {AI95-00072-01} This function returns the `Numeric` value for `Item`, represented in accordance with `Format`. The length of the returned value is `Length(Format)`, and the lower bound is 1. `Conversion_Error` is propagated if `Num` is negative and `Format` is `Unsigned`.
- 72 **function** `Valid` (`Item` : **in** `Packed_Decimal`;
 `Format` : **in** `Packed_Format`) **return** `Boolean`;
- 73 This function returns `True` if `Item` has a value consistent with `Format`, and `False` otherwise. The rules for the formation of `Packed_Decimal` values are implementation defined.
- 74 **function** `Length` (`Format` : **in** `Packed_Format`) **return** `Natural`;
- 75 This function returns the minimal length of a `Packed_Decimal` value sufficient to hold any value of type `Num` when represented as `Format`.
- 76 **function** `To_Decimal` (`Item` : **in** `Packed_Decimal`;
 `Format` : **in** `Packed_Format`) **return** `Num`;
- 77 Produces a value of type `Num` corresponding to `Item` as represented by `Format`. `Num'Scale` is the number of digits after the assumed radix point in `Item`. `Conversion_Error` is propagated if the value represented by `Item` is outside the range of `Num`.
- 78 **function** `To_Packed` (`Item` : **in** `Num`;
 `Format` : **in** `Packed_Format`) **return** `Packed_Decimal`;
- 79/1 {8652/0067} {AI95-00072-01} This function returns the `Packed_Decimal` value for `Item`, represented in accordance with `Format`. The length of the returned value is `Length(Format)`, and the lower bound is 1. `Conversion_Error` is propagated if `Num` is negative and `Format` is `Packed_Unsigned`.
- 80 **function** `Valid` (`Item` : **in** `Byte_Array`;
 `Format` : **in** `Binary_Format`) **return** `Boolean`;
- 81 This function returns `True` if `Item` has a value consistent with `Format`, and `False` otherwise.
- 81.a **Ramification:** This function returns `False` only when the represented value is outside the range of `Num`.
- 82 **function** `Length` (`Format` : **in** `Binary_Format`) **return** `Natural`;
- 83 This function returns the minimal length of a `Byte_Array` value sufficient to hold any value of type `Num` when represented as `Format`.

function To_Decimal (Item : in Byte_Array; Format : in Binary_Format) return Num;	84
Produces a value of type Num corresponding to Item as represented by Format. Num'Scale is the number of digits after the assumed radix point in Item. Conversion_Error is propagated if the value represented by Item is outside the range of Num.	85
function To_Binary (Item : in Num; Format : in Binary_Format) return Byte_Array;	86
{8652/0067} {AI95-00072-01} This function returns the Byte_Array value for Item, represented in accordance with Format. The length of the returned value is Length(Format), and the lower bound is 1.	87/1
function To_Decimal (Item : in Binary) return Num;	88
function To_Decimal (Item : in Long_Binary) return Num;	
These functions convert from COBOL binary format to a corresponding value of the decimal type Num. Conversion_Error is propagated if Item is too large for Num.	89
Ramification: There is no rescaling performed on the conversion. That is, the returned value in each case is a “bit copy” if Num has a binary radix. The programmer is responsible for maintaining the correct scale.	89.a
function To_Binary (Item : in Num) return Binary;	90
function To_Long_Binary (Item : in Num) return Long_Binary;	
These functions convert from Ada decimal to COBOL binary format. Conversion_Error is propagated if the value of Item is too large to be represented in the result type.	91
Discussion: One style of interface supported for COBOL, similar to what is provided for C, is the ability to call and pass parameters to an existing COBOL program. Thus the interface package supplies types that can be used in an Ada program as parameters to subprograms whose bodies will be in COBOL. These types map to COBOL's alphanumeric and numeric data categories.	91.a
Several types are provided for support of alphanumeric data. Since COBOL's run-time character set is not necessarily the same as Ada's, Interfaces.COBOL declares an implementation-defined character type COBOL_Character, and mappings between Character and COBOL_Character. These mappings are visible variables (rather than, say, functions or constant arrays), since in the situation where COBOL_Character is EBCDIC, the flexibility of dynamically modifying the mappings is needed. Corresponding to COBOL's alphanumeric data is the string type Alphanumeric.	91.b
Numeric data may have either a “display” or “computational” representation in COBOL. On the Ada side, the data is of a decimal fixed point type. Passing an Ada decimal data item to a COBOL program requires conversion from the Ada decimal type to some type that reflects the representation expected on the COBOL side.	91.c
• Computational Representation	91.d
Floating point representation is modeled by Ada floating point types, Floating and Long_Floating. Conversion between these types and Ada decimal types is obtained directly, since the type name serves as a conversion function.	91.e
Binary representation is modeled by an Ada integer type, Binary, and possibly other types such as Long_Binary. Conversion between, say, Binary and a decimal type is through functions from an instantiation of the generic package Decimal_Conversions.	91.f
Packed decimal representation is modeled by the Ada array type Packed_Decimal. Conversion between packed decimal and a decimal type is through functions from an instantiation of the generic package Decimal_Conversions.	91.g
• Display Representation	91.h
Display representation for numeric data is modeled by the array type Numeric. Conversion between display representation and a decimal type is through functions from an instantiation of the generic package Decimal_Conversions. A parameter to the conversion function indicates the desired interpretation of the data (e.g., signed leading separate, etc.)	91.i
{AI05-0229-1} The Convention of a record type may be specified as COBOL to direct the compiler to choose a COBOL-compatible representation for objects of the type.	91.j/3

91.k The package `Interfaces.COBOL` allows the Ada programmer to deal with data from files (or databases) created by a COBOL program. For data that is alphanumeric, or in display or packed decimal format, the approach is the same as for passing parameters (instantiate `Decimal_Conversions` to obtain the needed conversion functions). For binary data, the external representation is treated as a Byte array, and an instantiation of `Decimal_IO` produces a package that declares the needed conversion functions. A parameter to the conversion function indicates the desired interpretation of the data (e.g., high- versus low-order byte first).

Implementation Requirements

92/3 *{AI05-0229-1}* An implementation shall support specifying aspect `Convention` with a COBOL *convention_identifier* for a COBOL-eligible type (see B.1).

92.a **Ramification:** An implementation supporting this package shall ensure that if the bounds of a `Packed_Decimal`, `Alphanumeric`, or `Numeric` variable are static, then the representation of the object comprises solely the array components (that is, there is no implicit run-time “descriptor” that is part of the object).

Implementation Permissions

93 An implementation may provide additional constants of the private types `Display_Format`, `Binary_Format`, or `Packed_Format`.

93.a **Reason:** This is to allow exploitation of other external formats that may be available in the COBOL implementation.

94 An implementation may provide further floating point and integer types in `Interfaces.COBOL` to match additional native COBOL types, and may also supply corresponding conversion functions in the generic package `Decimal_Conversions`.

Implementation Advice

95 An Ada implementation should support the following interface correspondences between Ada and COBOL.

- 96 • An Ada **access** T parameter is passed as a “BY REFERENCE” data item of the COBOL type corresponding to T.
- 97 • An Ada **in** scalar parameter is passed as a “BY CONTENT” data item of the corresponding COBOL type.
- 98 • Any other Ada parameter is passed as a “BY REFERENCE” data item of the COBOL type corresponding to the Ada parameter type; for scalars, a local copy is used if necessary to ensure by-copy semantics.

98.a/2 **Implementation Advice:** If COBOL interfacing is supported, the interface correspondences between Ada and COBOL should be supported.

NOTES

99/3 12 *{AI05-0229-1}* An implementation is not required to support specifying aspect `Convention` for access types, nor is it required to support specifying aspects `Import`, `Export`, or `Convention` for functions.

99.a **Reason:** COBOL does not have a pointer facility, and a COBOL program does not return a value.

100 13 If an Ada subprogram is exported to COBOL, then a call from COBOL call may specify either “BY CONTENT” or “BY REFERENCE”.

Examples

101 *Examples of Interfaces.COBOL:*

```
102 with Interfaces.COBOL;
    procedure Test_Call is
```

```

-- Calling a foreign COBOL program
-- Assume that a COBOL program PROG has the following declaration
-- in its LINKAGE section:
-- 01 Parameter-Area
-- 05 NAME PIC X(20).

            SSN       : String(1..9);
            Salary    : Salary_Type;
            Adjust    : Adjustments_Type;
        end record;
119     COBOL_Record : COBOL_Employee_Record_Type;
     Ada_Record   : Ada_Employee_Record_Type;
120     package Salary_Conversions is
        new COBOL.Decimal_Conversions(Salary_Type);
     use Salary_Conversions;
121     package Adjustments_Conversions is
        new COBOL.Decimal_Conversions(Adjustments_Type);
     use Adjustments_Conversions;
122     begin
     Open (COBOL_File, Name => "Some_File");
123     loop
     Read (COBOL_File, COBOL_Record);
124     Ada_Record.Name := To_Ada(COBOL_Record.Name);
     Ada_Record.SSN := To_Ada(COBOL_Record.SSN);
     Ada_Record.Salary :=
         To_Decimal(COBOL_Record.Salary, COBOL.High_Order_First);
     Ada_Record.Adjust :=
         To_Decimal(COBOL_Record.Adjust, COBOL.Leading_Separate);
     ... -- Process Ada_Record
     end loop;
     exception
     when End_Error => ...
     end Test_External_Formats;

```

Wording Changes from Ada 95

124.a/2 {8652/0066} {AI95-00071-01} **Corrigendum:** Corrected the definition of Valid to match COBOL.

124.b/2 {8652/0067} {AI95-00072-01} **Corrigendum:** Specified the bounds of the results of To_Display, To_Packed, and To_Binary.

B.5 Interfacing with Fortran

1/3 {AI05-0229-1} The facilities relevant to interfacing with the Fortran language are the package Interfaces.Fortran and support for specifying the Convention aspect with *convention_identifier* Fortran.

2 The package Interfaces.Fortran defines Ada types whose representations are identical to the default representations of the Fortran intrinsic types Integer, Real, Double Precision, Complex, Logical, and Character in a supported Fortran implementation. These Ada types can therefore be used to pass objects between Ada and Fortran programs.

Static Semantics

3 The library package Interfaces.Fortran has the following declaration:

```

4     with Ada.Numerics.Generic_Complex_Types; -- see G.1.1
     pragma Elaborate_All(Ada.Numerics.Generic_Complex_Types);
     package Interfaces.Fortran is
         pragma Pure(Fortran);
5         type Fortran_Integer is range implementation-defined;
6         type Real           is digits implementation-defined;
         type Double_Precision is digits implementation-defined;
7         type Logical is new Boolean;

```

```

package Single_Precision_Complex_Types is
    new Ada.Numerics.Generic_Complex_Types (Real);
type Complex is new Single_Precision_Complex_Types.Complex;
subtype Imaginary is Single_Precision_Complex_Types.Imaginary;
i : Imaginary renames Single_Precision_Complex_Types.i;
j : Imaginary renames Single_Precision_Complex_Types.j;
type Character_Set is implementation-defined character type;
{AI05-0229-1} type Fortran_Character is array (Positive range <>) of
Character_Set
    with Pack;
function To_Fortran (Item : in Character) return Character_Set;
function To_Ada (Item : in Character_Set) return Character;
function To_Fortran (Item : in String) return Fortran_Character;
function To_Ada (Item : in Fortran_Character) return String;
procedure To_Fortran (Item      : in String;
                    Target    : out Fortran_Character;
                    Last      : out Natural);
procedure To_Ada (Item      : in Fortran_Character;
                Target    : out String;
                Last      : out Natural);
end Interfaces.Fortran;

```

Implementation defined: The types Fortran_Integer, Real, Double_Precision, and Character_Set in Interfaces.Fortran.

Ramification: The means by which the Complex type is provided in Interfaces.Fortran creates a dependence of Interfaces.Fortran on Numerics.Generic_Complex_Types (see G.1.1). This dependence is intentional and unavoidable, if the Fortran-compatible Complex type is to be useful in Ada code without duplicating facilities defined elsewhere.

The types Fortran_Integer, Real, Double_Precision, Logical, Complex, and Fortran_Character are Fortran-compatible.

The To_Fortran and To_Ada functions map between the Ada type Character and the Fortran type Character_Set, and also between the Ada type String and the Fortran type Fortran_Character. The To_Fortran and To_Ada procedures have analogous effects to the string conversion subprograms found in Interfaces.COBOL.

Implementation Requirements

{AI05-0229-1} An implementation shall support specifying aspect Convention with a Fortran convention_identifier for a Fortran-eligible type (see B.1).

Implementation Permissions

An implementation may add additional declarations to the Fortran interface packages. For example, the Fortran interface package for an implementation of Fortran 77 (ANSI X3.9-1978) that defines types like Integer*n, Real*n, Logical*n, and Complex*n may contain the declarations of types named Integer_Star_n, Real_Star_n, Logical_Star_n, and Complex_Star_n. (This convention should not apply to Character*n, for which the Ada analog is the constrained array subtype Fortran_Character (1..n).) Similarly, the Fortran interface package for an implementation of Fortran 90 that provides multiple kinds of intrinsic types, e.g. Integer (Kind=n), Real (Kind=n), Logical (Kind=n), Complex (Kind=n), and Character (Kind=n), may contain the declarations of types with the recommended names Integer_Kind_n, Real_Kind_n, Logical_Kind_n, Complex_Kind_n, and Character_Kind_n.

Discussion: Implementations may add auxiliary declarations as needed to assist in the declarations of additional Fortran-compatible types. For example, if a double precision complex type is defined, then Numerics.Generic_Complex_Types may be instantiated for the double precision type. Similarly, if a wide character type is defined to match a Fortran 90 wide character type (accessible in Fortran 90 with the Kind modifier), then an auxiliary character set may be declared to serve as its component type.

Implementation Advice

22 An Ada implementation should support the following interface correspondences between Ada and Fortran:

- 23 • An Ada procedure corresponds to a Fortran subroutine.
- 24 • An Ada function corresponds to a Fortran function.
- 25 • An Ada parameter of an elementary, array, or record type T is passed as a T_F argument to a Fortran procedure, where T_F is the Fortran type corresponding to the Ada type T, and where the INTENT attribute of the corresponding dummy argument matches the Ada formal parameter mode; the Fortran implementation's parameter passing conventions are used. For elementary types, a local copy is used if necessary to ensure by-copy semantics.
- 26 • An Ada parameter of an access-to-subprogram type is passed as a reference to a Fortran procedure whose interface corresponds to the designated subprogram's specification.

26.a/2 **Implementation Advice:** If Fortran interfacing is supported, the interface correspondences between Ada and Fortran should be supported.

NOTES

27 14 An object of a Fortran-compatible record type, declared in a library package or subprogram, can correspond to a Fortran common block; the type also corresponds to a Fortran “derived type”.

Examples

28 *Example of Interfaces.Fortran:*

```

29  with Interfaces.Fortran;
   use Interfaces.Fortran;
   procedure Ada_Application is
30/3 {AI05-0229-1}   type Fortran_Matrix is array (Integer range <>,
                  Integer range <>) of Double_Precision

```

Annex C

(normative)

Systems Programming

[The Systems Programming Annex specifies additional capabilities provided for low-level programming. These capabilities are also required in many real-time, embedded, distributed, and information systems.] 1

Extensions to Ada 83

This Annex is new to Ada 95. 1.a

C.1 Access to Machine Operations

{*AI05-0299-1*} [This subclause specifies rules regarding access to machine instructions from within an Ada program.] 1/3

Implementation defined: Implementation-defined intrinsic subprograms. 1.a/2

Implementation Requirements

The implementation shall support machine code insertions (see 13.8) or intrinsic subprograms (see 6.3.1) (or both). Implementation-defined attributes shall be provided to allow the use of Ada entities as operands. 2

Implementation Advice

The machine code or intrinsics support should allow access to all operations normally available to assembly language programmers for the target environment, including privileged instructions, if any. 3

Implementation Advice: The machine code or intrinsics support should allow access to all operations normally available to assembly language programmers for the target environment. 3.a/2

Ramification: Of course, on a machine with protection, an attempt to execute a privileged instruction in user mode will probably trap. Nonetheless, we want implementations to provide access to them so that Ada can be used to write systems programs that run in privileged mode. 3.a

{*AI05-0229-1*} The support for interfacing aspects (see Annex B) should include interface to assembler; the default assembler should be associated with the convention identifier Assembler. 4/3

Implementation Advice: Interface to assembler should be supported; the default assembler should be associated with the convention identifier Assembler. 4.a/2

If an entity is exported to assembly language, then the implementation should allocate it at an addressable location, and should ensure that it is retained by the linking process, even if not otherwise referenced from the Ada code. The implementation should assume that any call to a machine code or assembler subprogram is allowed to read or update every object that is specified as exported. 5

Implementation Advice: If an entity is exported to assembly language, then the implementation should allocate it at an addressable location even if not otherwise referenced from the Ada code. A call to a machine code or assembler subprogram should be treated as if it could read or update every object that is specified as exported. 5.a/2

Documentation Requirements

The implementation shall document the overhead associated with calling machine-code or intrinsic subprograms, as compared to a fully-inlined call, and to a regular out-of-line call. 6

Documentation Requirement: The overhead of calling machine-code or intrinsic subprograms. 6.a/2

The implementation shall document the types of the package `System.Machine_Code` usable for machine code insertions, and the attributes to be used in machine code insertions for references to Ada entities. 7

- 7.a/2 **Documentation Requirement:** The types and attributes used in machine code insertions.
- 8/3 {AI05-0229-1} The implementation shall document the subprogram calling conventions associated with the convention identifiers available for use with the Convention aspect (Ada and Assembler, at a minimum), including register saving, exception propagation, parameter passing, and function value returning.
- 8.a/2 **Documentation Requirement:** The subprogram calling conventions for all supported convention identifiers.
- 9 For exported and imported subprograms, the implementation shall document the mapping between the Link_Name string, if specified, or the Ada designator, if not, and the external link name used for such a subprogram.
- 9.a/2 *This paragraph was deleted.*
- 9.b/2 **Documentation Requirement:** The mapping between the Link_Name or Ada designator and the external link name.
- Implementation Advice*
- 10 The implementation should ensure that little or no overhead is associated with calling intrinsic and machine-code subprograms.
- 10.a/2 **Implementation Advice:** Little or no overhead should be associated with calling intrinsic and machine-code subprograms.
- 11 It is recommended that intrinsic subprograms be provided for convenient access to any machine operations that provide special capabilities or efficiency and that are not otherwise available through the language constructs. Examples of such instructions include:
- 12 • Atomic read-modify-write operations — e.g., test and set, compare and swap, decrement and test, enqueue/dequeue.
- 13 • Standard numeric functions — e.g., *sin*, *log*.
- 14 • String manipulation operations — e.g., translate and test.
- 15 • Vector operations — e.g., compare vector against thresholds.
- 16 • Direct operations on I/O ports.
- 16.a/2 **Implementation Advice:** Intrinsic subprograms should be provided to access any machine operations that provide special capabilities or efficiency not normally available.

C.2 Required Representation Support

- 1/3 {AI95-00434-01} {AI05-0299-1} This subclause specifies minimal requirements on the support for representation items and related features.

Implementation Requirements

- 2/3 {AI05-0299-1} The implementation shall support at least the functionality defined by the recommended levels of support in Clause 13.

C.3 Interrupt Support

- 1/3 {AI05-0299-1} [This subclause specifies the language-defined model for hardware interrupts in addition to mechanisms for handling interrupts.]

Dynamic Semantics

- 2 [An *interrupt* represents a class of events that are detected by the hardware or the system software.] Interrupts are said to occur. An *occurrence* of an interrupt is separable into generation and delivery.

Generation of an interrupt is the event in the underlying hardware or system that makes the interrupt available to the program. *Delivery* is the action that invokes part of the program as response to the interrupt occurrence. Between generation and delivery, the interrupt occurrence [(or interrupt)] is *pending*. Some or all interrupts may be *blocked*. When an interrupt is blocked, all occurrences of that interrupt are prevented from being delivered. Certain interrupts are *reserved*. The set of reserved interrupts is implementation defined. A reserved interrupt is either an interrupt for which user-defined handlers are not supported, or one which already has an attached handler by some other implementation-defined means. Program units can be connected to nonreserved interrupts. While connected, the program unit is said to be *attached* to that interrupt. The execution of that program unit, the *interrupt handler*, is invoked upon delivery of the interrupt occurrence.

This paragraph was deleted.

2.a/2

To be honest: As an obsolescent feature, interrupts may be attached to task entries by an address clause. See J.7.1.

2.b

While a handler is attached to an interrupt, it is called once for each delivered occurrence of that interrupt. While the handler executes, the corresponding interrupt is blocked.

3

While an interrupt is blocked, all occurrences of that interrupt are prevented from being delivered. Whether such occurrences remain pending or are lost is implementation defined.

4

Each interrupt has a *default treatment* which determines the system's response to an occurrence of that interrupt when no user-defined handler is attached. The set of possible default treatments is implementation defined, as is the method (if one exists) for configuring the default treatments for interrupts.

5

An interrupt is delivered to the handler (or default treatment) that is in effect for that interrupt at the time of delivery.

6

An exception propagated from a handler that is invoked by an interrupt has no effect.

7

[If the `Ceiling_Locking` policy (see D.3) is in effect, the interrupt handler executes with the active priority that is the ceiling priority of the corresponding protected object.]

8

Implementation Requirements

The implementation shall provide a mechanism to determine the minimum stack space that is needed for each interrupt handler and to reserve that space for the execution of the handler. [This space should accommodate nested invocations of the handler where the system permits this.]

9

If the hardware or the underlying system holds pending interrupt occurrences, the implementation shall provide for later delivery of these occurrences to the program.

10

If the `Ceiling_Locking` policy is not in effect, the implementation shall provide means for the application to specify whether interrupts are to be blocked during protected actions.

11

Documentation Requirements

The implementation shall document the following items:

12

Discussion: This information may be different for different forms of interrupt handlers.

12.a

1. For each interrupt, which interrupts are blocked from delivery when a handler attached to that interrupt executes (either as a result of an interrupt delivery or of an ordinary call on a procedure of the corresponding protected object).
2. Any interrupts that cannot be blocked, and the effect of attaching handlers to such interrupts, if this is permitted.

13

14

- 15 3. Which run-time stack an interrupt handler uses when it executes as a result of an interrupt
delivery; if this is configurable, what is the mechanism to do so; how to specify how much space
to reserve on that stack.
- 16 4. Any implementation- or hardware-specific activity that happens before a user-defined interrupt
handler gets control (e.g., reading device registers, acknowledging devices).
- 17 5. Any timing or other limitations imposed on the execution of interrupt handlers.
- 18 6. The state (blocked/unblocked) of the nonreserved interrupts when the program starts; if some
interrupts are unblocked, what is the mechanism a program can use to protect itself before it can
attach the corresponding handlers.
- 19 7. Whether the interrupted task is allowed to resume execution before the interrupt handler returns.
- 20 8. The treatment of interrupt occurrences that are generated while the interrupt is blocked; i.e.,
whether one or more occurrences are held for later delivery, or all are lost.
- 21 9. Whether predefined or implementation-defined exceptions are raised as a result of the occurrence
of any interrupt, and the mapping between the machine interrupts (or traps) and the predefined
exceptions.
- 22 10.
On a multi-processor, the rules governing the delivery of an interrupt to a particular processor.

22.a/2 **Documentation Requirement:** The treatment of interrupts.

Implementation Permissions

23/2 {AI95-00434-01} If the underlying system or hardware does not allow interrupts to be blocked, then no
blocking is required [as part of the execution of subprograms of a protected object for which one of its
subprograms is an interrupt handler].

24 In a multi-processor with more than one interrupt subsystem, it is implementation defined whether (and
how) interrupt sources from separate subsystems share the same Interrupt_Id type (see C.3.2). In
particular, the meaning of a blocked or pending interrupt may then be applicable to one processor only.

24.a **Discussion:** This issue is tightly related to the issue of scheduling on a multi-processor. In a sense, if a particular
interrupt source is not available to all processors, the system is not truly homogeneous.

24.b One way to approach this problem is to assign sub-ranges within Interrupt_Id to each interrupt subsystem, such that
“similar” interrupt sources (e.g. a timer) in different subsystems get a distinct id.

25 Implementations are allowed to impose timing or other limitations on the execution of interrupt handlers.

25.a **Reason:** These limitations are often necessary to ensure proper behavior of the implementation.

26/3 {AI95-00434-01} {AI05-0299-1} Other forms of handlers are allowed to be supported, in which case the
rules of this subclause should be adhered to.

27 The active priority of the execution of an interrupt handler is allowed to vary from one occurrence of the
same interrupt to another.

Implementation Advice

28/2 {AI95-00434-01} If the Ceiling_Locking policy is not in effect, the implementation should provide means
for the application to specify which interrupts are to be blocked during protected actions, if the underlying
system allows for finer-grained control of interrupt blocking.

28.a/2 **Implementation Advice:** If the Ceiling_Locking policy is not in effect and the target system allows for finer-grained
control of interrupt blocking, a means for the application to specify which interrupts are to be blocked during protected
actions should be provided.

NOTES

- 1 The default treatment for an interrupt can be to keep the interrupt pending or to deliver it to an implementation-defined handler. Examples of actions that an implementation-defined handler is allowed to perform include aborting the partition, ignoring (i.e., discarding occurrences of) the interrupt, or queuing one or more occurrences of the interrupt for possible later delivery when a user-defined handler is attached to that interrupt. 29
- 2 It is a bounded error to call `Task_Identification.Current_Task` (see C.7.1) from an interrupt handler. 30
- 3 The rule that an exception propagated from an interrupt handler has no effect is modeled after the rule about exceptions propagated out of task bodies. 31

C.3.1 Protected Procedure Handlers

Paragraphs 1 through 6 were moved to Annex J, “Obsolescent Features”.

Static Semantics

{AI05-0229-1} For a parameterless protected procedure, the following language-defined representation aspects may be specified: 6.1/3

`Interrupt_Handler` 6.2/3

The type of aspect `Interrupt_Handler` is Boolean. If directly specified, the aspect_definition shall be a static expression. [This aspect is never inherited;] if not directly specified, the aspect is False.

Aspect Description for `Interrupt_Handler`: Protected procedure may be attached to interrupts. 6.a/3

`Attach_Handler` 6.3/3

The aspect `Attach_Handler` is an expression, which shall be of type `Interrupts.Interrupt_Id`. [This aspect is never inherited.]

Aspect Description for `Attach_Handler`: Protected procedure is attached to an interrupt. 6.b/3

Legality Rules

{AI95-00434-01} {AI05-0033-1} {AI05-0229-1} If either the `Attach_Handler` or `Interrupt_Handler` aspect are specified for a protected procedure, the corresponding `protected_type_declaration` or `single_protected_declaration` shall be a library-level declaration and shall not be declared within a generic body. In addition to the places where Legality Rules normally apply (see 12.3), this rule also applies in the private part of an instance of a generic unit. 7/3

Discussion: In the case of a `protected_type_declaration`, an `object_declaration` of an object of that type need not be at library level. 7.a

{AI05-0033-1} {AI05-0229-1} We cannot allow these aspects in protected declarations in a generic body, because legality rules are not checked for instance bodies, and these should not be allowed if the instance is not at the library level. The protected types can be declared in the private part if this is desired. Note that while the 'Access to use the handler would provide the check in the case of `Interrupt_Handler`, there is no other check for `Attach_Handler`. Since these aspects are so similar, we want the rules to be the same. 7.b/3

This paragraph was deleted. {AI95-00253-01} {AI95-00303-01} {AI05-0033-1} 8/3

Dynamic Semantics

{AI05-0229-1} If the `Interrupt_Handler` aspect of a protected procedure is True, then the procedure may be attached dynamically, as a handler, to interrupts (see C.3.2). [Such procedures are allowed to be attached to multiple interrupts.] 9/3

{AI05-0229-1} The expression specified for the `Attach_Handler` aspect of a protected procedure *P* is evaluated as part of the creation of the protected object that contains *P*. The value of the expression identifies an interrupt. As part of the initialization of that object, *P* (the *handler* procedure) is attached to the identified interrupt. A check is made that the corresponding interrupt is not reserved. `Program_Error` is raised if the check fails, and the existing treatment for the interrupt is not affected. 10/3

11/3 {AI95-00434-01} {AI05-0229-1} If the Ceiling_Locking policy (see D.3) is in effect, then upon the initialization of a protected object that contains a protected procedure for which either the Attach_Handler aspect is specified or the Interrupt_Handler aspect is True, a check is made that the initial ceiling priority of the object is in the range of System.Interrupt_Priority. If the check fails, Program_Error is raised.

12/3 {8652/0068} {AI95-00121-01} {AI05-0229-1} When a protected object is finalized, for any of its procedures that are attached to interrupts, the handler is detached. If the handler was attached by a procedure in the Interrupts package or if no user handler was previously attached to the interrupt, the default treatment is restored. If the Attach_Handler aspect was specified and the most recently attached handler for the same interrupt is the same as the one that was attached at the time the protected object was initialized, the previous handler is restored.

12.a/3 **Discussion:** {8652/0068} {AI95-00121-01} {AI95-00303-01} {AI05-0229-1} If all protected objects for interrupt handlers are declared at the library level, the finalization discussed above occurs only as part of the finalization of all library-level packages in a partition. However, objects of a protected type containing procedures with an Attach_Handler aspect specified need not be at the library level. Thus, an implementation needs to be able to restore handlers during the execution of the program. (An object with an Interrupt_Handler aspect also need not be at the library level, but such a handler cannot be attached to an interrupt using the Interrupts package.)

13 When a handler is attached to an interrupt, the interrupt is blocked [(subject to the Implementation Permission in C.3)] during the execution of every protected action on the protected object containing the handler.

Erroneous Execution

14 If the Ceiling_Locking policy (see D.3) is in effect and an interrupt is delivered to a handler, and the interrupt hardware priority is higher than the ceiling priority of the corresponding protected object, the execution of the program is erroneous.

14.1/3 {8652/0068} {AI95-00121-01} {AI05-0229-1} If the handlers for a given interrupt attached via aspect Attach_Handler are not attached and detached in a stack-like (LIFO) order, program execution is erroneous. In particular, when a protected object is finalized, the execution is erroneous if any of the procedures of the protected object are attached to interrupts via aspect Attach_Handler and the most recently attached handler for the same interrupt is not the same as the one that was attached at the time the protected object was initialized.

14.a/3 **Discussion:** {8652/0068} {AI95-00121-01} {AI05-0229-1} This simplifies implementation of the Attach_Handler aspect by not requiring a check that the current handler is the same as the one attached by the initialization of a protected object.

Metrics

15 The following metric shall be documented by the implementation:

- 16/2 • {AI95-00434-01} The worst-case overhead for an interrupt handler that is a parameterless protected procedure, in clock cycles. This is the execution time not directly attributable to the handler procedure or the interrupted execution. It is estimated as $C - (A+B)$, where A is how long it takes to complete a given sequence of instructions without any interrupt, B is how long it takes to complete a normal call to a given protected procedure, and C is how long it takes to complete the same sequence of instructions when it is interrupted by one execution of the same procedure called via an interrupt.

16.a **Implementation Note:** The instruction sequence and interrupt handler used to measure interrupt handling overhead should be chosen so as to maximize the execution time cost due to cache misses. For example, if the processor has cache memory and the activity of an interrupt handler could invalidate the contents of cache memory, the handler should be written such that it invalidates all of the cache memory.

16.b/2 **Documentation Requirement:** The metrics for interrupt handlers.

Implementation Permissions

{AI05-0229-1} When the aspects `Attach_Handler` or `Interrupt_Handler` are specified for a protected procedure, the implementation is allowed to impose implementation-defined restrictions on the corresponding `protected_type_declaration` and `protected_body`. 17/3

Ramification: The restrictions may be on the constructs that are allowed within them, and on ordinary calls (i.e. not via interrupts) on protected operations in these protected objects. 17.a

Implementation defined: Any restrictions on a protected procedure or its containing type when an aspect `Attach_handler` or `Interrupt_Handler` is specified. 17.b/3

An implementation may use a different mechanism for invoking a protected procedure in response to a hardware interrupt than is used for a call to that protected procedure from a task. 18

Discussion: This is despite the fact that the priority of an interrupt handler (see D.1) is modeled after a hardware task calling the handler. 18.a

{AI05-0229-1} Notwithstanding what this subclause says elsewhere, the `Attach_Handler` and `Interrupt_Handler` aspects are allowed to be used for other, implementation defined, forms of interrupt handlers. 19/3

Ramification: {AI05-0229-1} For example, if an implementation wishes to allow interrupt handlers to have parameters, it is allowed to do so via these aspects; it need not invent implementation-defined aspects for the purpose. 19.a/3

Implementation defined: Any other forms of interrupt handler supported by the `Attach_Handler` and `Interrupt_Handler` aspects. 19.b/3

Implementation Advice

Whenever possible, the implementation should allow interrupt handlers to be called directly by the hardware. 20

Implementation Advice: Interrupt handlers should be called directly by the hardware. 20.a/2

Whenever practical, the implementation should detect violations of any implementation-defined restrictions before run time. 21

Implementation Advice: Violations of any implementation-defined restrictions on interrupt handlers should be detected before run time. 21.a/2

NOTES

4 {AI05-0229-1} The `Attach_Handler` aspect may provide static attachment of handlers to interrupts if the implementation supports preelaboration of protected objects. (See C.4.) 22/3

5 {AI95-00434-01} A protected object that has a (protected) procedure attached to an interrupt should have a ceiling priority at least as high as the highest processor priority at which that interrupt will ever be delivered. 23/2

6 Protected procedures can also be attached dynamically to interrupts via operations declared in the predefined package `Interrupts`. 24

7 An example of a possible implementation-defined restriction is disallowing the use of the standard storage pools within the body of a protected procedure that is an interrupt handler. 25

Incompatibilities With Ada 95

{AI95-00253-01} **Amendment Correction:** Corrected the wording so that the rules for the use of `Attach_Handler` and `Interrupt_Handler` are identical. This means that uses of `pragma Interrupt_Handler` outside of the target protected type or single protected object are now illegal. 25.a/2

Wording Changes from Ada 95

{8652/0068} {AI95-00121-01} **Corrigendum:** Clarified the meaning of “the previous handler” when finalizing protected objects containing interrupt handlers. 25.b/2

{AI95-00303-01} Dropped the requirement that an object of a type containing an `Interrupt_Handler` pragma must be declared at the library level. This was a generic contract model violation. This change is not an extension, as an attempt to attach such a handler with a routine in package `Interrupts` will fail an accessibility check anyway. Moreover, implementations can retain the rule as an implementation-defined restriction on the use of the type, as permitted by the Implementation Permissions above. 25.c/2

Extensions to Ada 2005

- 25.d/3 {AI05-0229-1} Aspects `Interrupt_Handler` and `Attach_Handler` are new; pragmas `Interrupt_Handler` and `Attach_Handler` are now obsolescent.

Wording Changes from Ada 2005

- 25.e/3 {AI05-0033-1} **Correction:** Added missing generic contract wording for the aspects `Attach_Handler` and `Interrupt_Handler`.

C.3.2 The Package `Interrupts`

Static Semantics

1 The following language-defined packages exist:

```

2/3 {AI05-0167-1} with System;
with System.Multiprocessors;
package Ada.Interrupts is
  type Interrupt_Id is implementation-defined;
  type Parameterless_Handler is
    access protected procedure;
3/1 This paragraph was deleted.
4   function Is_Reserved (Interrupt : Interrupt_Id)
      return Boolean;
5   function Is_Attached (Interrupt : Interrupt_Id)
      return Boolean;
6   function Current_Handler (Interrupt : Interrupt_Id)
      return Parameterless_Handler;
7   procedure Attach_Handler
      (New_Handler : in Parameterless_Handler;
       Interrupt   : in Interrupt_Id);
8   procedure Exchange_Handler
      (Old_Handler : out Parameterless_Handler;
       New_Handler : in Parameterless_Handler;
       Interrupt   : in Interrupt_Id);
9   procedure Detach_Handler
      (Interrupt : in Interrupt_Id);
10  function Reference (Interrupt : Interrupt_Id)
      return System.Address;
10.1/3 {AI05-0167-1} function Get_CPU (Interrupt : Interrupt_Id)
      return System.Multiprocessors.CPU_Range;
11 private
    ... -- not specified by the language
end Ada.Interrupts;
12 package Ada.Interrupts.Names is
  implementation-defined : constant Interrupt_Id :=
    implementation-defined;
    .
    .
  implementation-defined : constant Interrupt_Id :=
    implementation-defined;
end Ada.Interrupts.Names;
```

Dynamic Semantics

- 13 The `Interrupt_Id` type is an implementation-defined discrete type used to identify interrupts.
- 14 The `Is_Reserved` function returns `True` if and only if the specified interrupt is reserved.
- 15 The `Is_Attached` function returns `True` if and only if a user-specified interrupt handler is attached to the interrupt.

- {8652/0069} {AI95-00166-01} The `Current_Handler` function returns a value that represents the attached handler of the interrupt. If no user-defined handler is attached to the interrupt, `Current_Handler` returns **null**. 16/1
- {AI05-0229-1} The `Attach_Handler` procedure attaches the specified handler to the interrupt, overriding any existing treatment (including a user handler) in effect for that interrupt. If `New_Handler` is **null**, the default treatment is restored. If `New_Handler` designates a protected procedure for which the aspect `Interrupt_Handler` is `False`, `Program_Error` is raised. In this case, the operation does not modify the existing interrupt treatment. 17/3
- {8652/0069} {AI95-00166-01} The `Exchange_Handler` procedure operates in the same manner as `Attach_Handler` with the addition that the value returned in `Old_Handler` designates the previous treatment for the specified interrupt. If the previous treatment is not a user-defined handler, **null** is returned. 18/1
- Ramification:** Calling `Attach_Handler` or `Exchange_Handler` with this value for `New_Handler` restores the previous handler. 18.a
- {8652/0069} {AI95-00166-01} If the application uses only parameterless procedures as handlers (other types of handlers may be provided by the implementation, but are not required by the standard), then if `Old_Handler` is not **null**, it may be called to execute the previous handler. This provides a way to cascade application interrupt handlers. However, the default handler cannot be cascaded this way (`Old_Handler` must be **null** for the default handler). 18.a.1/1
- The `Detach_Handler` procedure restores the default treatment for the specified interrupt. 19
- For all operations defined in this package that take a parameter of type `Interrupt_Id`, with the exception of `Is_Reserved` and `Reference`, a check is made that the specified interrupt is not reserved. `Program_Error` is raised if this check fails. 20
- {AI05-0229-1} If, by using the `Attach_Handler`, `Detach_Handler`, or `Exchange_Handler` procedures, an attempt is made to detach a handler that was attached statically (using the aspect `Attach_Handler`), the handler is not detached and `Program_Error` is raised. 21/3
- {AI95-00434-01} The `Reference` function returns a value of type `System.Address` that can be used to attach a task entry via an address clause (see J.7.1) to the interrupt specified by `Interrupt`. This function raises `Program_Error` if attaching task entries to interrupts (or to this particular interrupt) is not supported. 22/2
- {AI05-0153-3} The function `Get_CPU` returns the processor on which the handler for `Interrupt` is executed. If the handler can execute on more than one processor the value `System.Multiprocessors.Not_A_Specific_CPU` is returned. 22.1/3
- Implementation Requirements*
- At no time during attachment or exchange of handlers shall the current handler of the corresponding interrupt be undefined. 23
- Documentation Requirements*
- {AI95-00434-01} {AI05-0229-1} If the `Ceiling_Locking` policy (see D.3) is in effect, the implementation shall document the default ceiling priority assigned to a protected object that contains a protected procedure that specifies either the `Attach_Handler` or `Interrupt_Handler` aspects, but does not specify the `Interrupt_Priority` aspect. [This default need not be the same for all interrupts.] 24/3
- Documentation Requirement:** If the `Ceiling_Locking` policy is in effect, the default ceiling priority for a protected object that specifies an interrupt handler aspect. 24.a.1/3

Implementation Advice

If implementation-defined forms of interrupt handler procedures are supported, such as protected procedures with parameters, then for each such form of a handler, a type analogous to `Parameterless_` - 25

Handler should be specified in a child package of Interrupts, with the same operations as in the predefined package Interrupts.

- 25.a/2 **Implementation Advice:** If implementation-defined forms of interrupt handler procedures are supported, then for each such form of a handler, a type analogous to Parameterless_Handler should be specified in a child package of Interrupts, with the same operations as in the predefined package Interrupts.

NOTES

- 26 8 The package Interrupts.Names contains implementation-defined names (and constant values) for the interrupts that are supported by the implementation.

Examples

27 *Example of interrupt handlers:*

```
28/3 {AI05-0229-1} Device_Priority : constant
      array (1..5) of System.Interrupt_Priority := ( ... );
protected type Device_Interface
  (Int_Id : Ada.Interrupts.Interrupt_Id)
  with Interrupt_Priority => Device_Priority(Int_Id) is
  procedure Handler
  with Attach_Handler => Int_Id;
  ...
end Device_Interface;
...
Device_1_Driver : Device_Interface(1);
...
Device_5_Driver : Device_Interface(5);

```

Wording Changes from Ada 95

- 28.a/2 {8652/0069} {AI95-00166-01} **Corrigendum:** Clarified that the value returned by Current_Handler and Exchange_Handler for the default treatment is null.

Incompatibilities With Ada 2005

- 28.b/3 {AI05-0167-1} Functions Get_CPU is added to Interrupts. If Interrupts is referenced in a use_clause, and an entity E with a defining_identifier of Get_CPU is defined in a package that is also referenced in a use_clause, the entity E may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur.

C.4 Preelaboration Requirements

- 1/3 {AI05-0299-1} [This subclause specifies additional implementation and documentation requirements for the Preelaborate pragma (see 10.2.1).]

Implementation Requirements

- 2 The implementation shall not incur any run-time overhead for the elaboration checks of subprograms and protected_bodies declared in preelaborated library units.
- 3 The implementation shall not execute any memory write operations after load time for the elaboration of constant objects declared immediately within the declarative region of a preelaborated library package, so long as the subtype and initial expression (or default initial expressions if initialized by default) of the object_declaration satisfy the following restrictions. The meaning of *load time* is implementation defined.
- 3.a **Discussion:** On systems where the image of the partition is initially copied from disk to RAM, or from ROM to RAM, prior to starting execution of the partition, the intention is that “load time” consist of this initial copying step. On other systems, load time and run time might actually be interspersed.
- 4 • Any subtype_mark denotes a statically constrained subtype, with statically constrained subcomponents, if any;

- *{AI95-00161-01}* no `subtype_mark` denotes a controlled type, a private type, a private extension, a generic formal private type, a generic formal derived type, or a descendant of such a type; 4.1/2
 - Reason:** For an implementation that uses the registration method of finalization, a controlled object will require some code executed to register the object at the appropriate point. The other types are those that *might* have a controlled component. None of these types were allowed in preelaborated units in Ada 95. These types are covered by the Implementation Advice, of course, so they should still execute as little code as possible. 4.a.1/2
- any constraint is a static constraint; 5
- any allocator is for an access-to-constant type; 6
- any uses of predefined operators appear only within static expressions; 7
- any primaries that are names, other than `attribute_references` for the Access or Address attributes, appear only within static expressions; 8
 - Ramification:** This cuts out `attribute_references` that are not static, except for Access and Address. 8.a
- any name that is not part of a static expression is an expanded name or `direct_name` that statically denotes some entity; 9
 - Ramification:** This cuts out `function_calls` and `type_conversions` that are not static, including calls on attribute functions like 'Image and 'Value. 9.a
- any `discrete_choice` of an `array_aggregate` is static; 10
- no language-defined check associated with the elaboration of the `object_declaration` can fail. 11
 - Reason:** *{AI95-00114-01}* The intent is that aggregates all of whose scalar subcomponents are static and all of whose access subcomponents are **null**, allocators for access-to-constant types, or X'Access, will be supported with no run-time code generated. 11.a/2

Documentation Requirements

- The implementation shall document any circumstances under which the elaboration of a preelaborated package causes code to be executed at run time. 12
- Documentation Requirement:** Any circumstances when the elaboration of a preelaborated package causes code to be executed. 12.a/2
- The implementation shall document whether the method used for initialization of preelaborated variables allows a partition to be restarted without reloading. 13
- Documentation Requirement:** Whether a partition can be restarted without reloading. 13.a.1/2
 - This paragraph was deleted.* 13.a/2
 - Discussion:** *{AI95-00114-01}* This covers the issue of the run-time system itself being restartable, so that need not be a separate Documentation Requirement. 13.b/2

Implementation Advice

- It is recommended that preelaborated packages be implemented in such a way that there should be little or no code executed at run time for the elaboration of entities not already covered by the Implementation Requirements. 14
- Implementation Advice:** Preelaborated packages should be implemented such that little or no code is executed at run time for the elaboration of entities. 14.a/2

Wording Changes from Ada 95

- {AI95-00161-01}* Added wording to exclude the additional kinds of types allowed in preelaborated units from the Implementation Requirements. 14.b/2

C.5 Pragma Discard_Names

1 [A pragma Discard_Names may be used to request a reduction in storage used for the names of certain entities.]

Syntax

2 The form of a pragma Discard_Names is as follows:

3 **pragma** Discard_Names([(On =>] local_name)];

4 A pragma Discard_Names is allowed only immediately within a declarative_part, immediately within a package_specification, or as a configuration pragma.

Legality Rules

5 The local_name (if present) shall denote a nonderived enumeration [first] subtype, a tagged [first] subtype, or an exception. The pragma applies to the type or exception. Without a local_name, the pragma applies to all such entities declared after the pragma, within the same declarative region. Alternatively, the pragma can be used as a configuration pragma. If the pragma applies to a type, then it applies also to all descendants of the type.

Static Semantics

6 If a local_name is given, then a pragma Discard_Names is a representation pragma.

6.a/3 **Ramification:** {AI05-0229-1} Representation pragmas automatically specify aspects of the same name, so Discard_Names can be used as an aspect_mark in an aspect_specification instead of using the pragma on individual entities.

7/2 {AI95-00285-01} {AI95-00400-01} If the pragma applies to an enumeration type, then the semantics of the Wide_Wide_Image and Wide_Wide_Value attributes are implementation defined for that type[; the semantics of Image, Wide_Image, Value, and Wide_Value are still defined in terms of Wide_Wide_Image and Wide_Wide_Value]. In addition, the semantics of Text_IO.Enumeration_IO are implementation defined. If the pragma applies to a tagged type, then the semantics of the Tags.-Wide_Wide_Expanded_Name function are implementation defined for that type[; the semantics of Tags.-Expanded_Name and Tags.Wide_Expanded_Name are still defined in terms of Tags.Wide_Wide_Expanded_Name]. If the pragma applies to an exception, then the semantics of the Exceptions.-Wide_Wide_Exception_Name function are implementation defined for that exception[; the semantics of Exceptions.Exception_Name and Exceptions.Wide_Exception_Name are still defined in terms of Exceptions.Wide_Wide_Exception_Name].

7.a **Implementation defined:** The semantics of pragma Discard_Names.

7.b **Ramification:** The Width attribute is still defined in terms of Image.

7.c/2 {AI95-00285-01} The semantics of S'Wide_Wide_Image and S'Wide_Wide_Value are implementation defined for any subtype of an enumeration type to which the pragma applies. (The pragma actually names the first subtype, of course.)

Implementation Advice

8 If the pragma applies to an entity, then the implementation should reduce the amount of storage used for storing names associated with that entity.

8.a/2 **Implementation Advice:** If pragma Discard_Names applies to an entity, then the amount of storage used for storing names associated with that entity should be reduced.

8.b **Reason:** A typical implementation of the Image attribute for enumeration types is to store a table containing the names of all the enumeration literals. Pragma Discard_Names allows the implementation to avoid storing such a table without having to prove that the Image attribute is never used (which can be difficult in the presence of separate compilation).

We did not specify the semantics of the Image attribute in the presence of this pragma because different semantics might be desirable in different situations. In some cases, it might make sense to use the Image attribute to print out a useful value that can be used to identify the entity given information in compiler-generated listings. In other cases, it might make sense to get an error at compile time or at run time. In cases where memory is plentiful, the simplest implementation makes sense: ignore the pragma. Implementations that are capable of avoiding the extra storage in cases where the Image attribute is never used might also wish to ignore the pragma. 8.c

The same applies to the Tags.Expanded_Name and Exceptions.Exception_Name functions. 8.d

Wording Changes from Ada 95

{AI95-00285-01} {AI95-00400-01} Updated the wording to reflect that the double wide image and value functions are now the master versions that the others are defined from. 8.e/2

C.6 Shared Variable Control

{AI05-0229-1} {AI05-0299-1} [This subclause defines representation aspects that control the use of shared variables.] 1/3

Paragraphs 2 through 6 were moved to Annex J, “Obsolescent Features”.

Static Semantics

{AI05-0229-1} For an `object_declaration`, a `component_declaration`, or a `full_type_declaration`, the following representation aspects may be specified: 6.1/3

Atomic The type of aspect Atomic is Boolean. 6.2/3

Aspect Description for Atomic: Declare that a type, object, or component is atomic. 6.a/3

Independent The type of aspect Independent is Boolean. 6.3/3

Aspect Description for Independent: Declare that a type, object, or component is independently addressable. 6.b/3

Volatile The type of aspect Volatile is Boolean. 6.4/3

Aspect Description for Volatile: Declare that a type, object, or component is volatile. 6.c/3

{AI05-0229-1} For a `full_type_declaration` of an array type (including the anonymous type of an `object_declaration` of an anonymous array object), the following representation aspects may be specified: 6.5/3

Atomic_Components
The type of aspect Atomic_Components is Boolean. 6.6/3

Aspect Description for Atomic_Components: Declare that the components of an array type or object are atomic. 6.d/3

Volatile_Components
The type of aspect Volatile_Components is Boolean. 6.7/3

Aspect Description for Volatile_Components: Declare that the components of an array type or object are volatile. 6.e/3

{AI05-0229-1} For a `full_type_declaration` (including the anonymous type of an `object_declaration` of an anonymous array object), the following representation aspect may be specified: 6.8/3

Independent_Components
The type of aspect Independent_Components is Boolean. 6.9/3

Aspect Description for Independent_Components: Declare that the components of an array or record type, or an array object, are independently addressable. 6.f/3

{AI05-0229-1} If any of these aspects are directly specified, the `aspect_definition` shall be a static expression. If not specified (including by inheritance), each of these aspects is False. 6.10/3

{AI95-00272-01} {AI05-0229-1} An *atomic* type is one for which the aspect Atomic is True. An *atomic* object (including a component) is one for which the aspect Atomic is True, or a component of an array for which the aspect Atomic_Components is True for the associated type, or any object of an atomic type, other than objects obtained by evaluating a slice. 7/3

- 7.a/2 **Ramification:** {AI95-00272-01} A slice of an atomic array object is not itself atomic. That's necessary as executing a read or write of a dynamic number of components in a single instruction is not possible on many targets.
- 8./3 {AI05-0229-1} A *volatile* type is one for which the aspect Volatile is True. A *volatile* object (including a component) is one for which the aspect Volatile is True, or a component of an array for which the aspect Volatile_Components is True for the associated type, or any object of a volatile type. In addition, every atomic type or object is also defined to be volatile. Finally, if an object is volatile, then so are all of its subcomponents [(the same does not apply to atomic)].
- 8.1/3 {AI05-0009-1} {AI05-0229-1} When True, the aspects Independent and Independent_Components specify as *independently addressable* the named object or component(s), or in the case of a type, all objects or components of that type. All atomic objects are considered to be specified as independently addressable.
- 8.a/3 **Ramification:** If the compiler cannot guarantee that an object (including a component) for which aspect Independent or aspect Independent_Components is True is independently addressable from any other nonoverlapping object, then the aspect specification must be rejected.
- 8.b/3 Similarly, an atomic object (including atomic components) is always independently addressable from any other nonoverlapping object. Any representation item which would prevent this from being true should be rejected, notwithstanding what this Standard says elsewhere (specifically, in the Recommended Level of Support).

Paragraph 9 was moved to Annex J, “Obsolescent Features”.

Legality Rules

- 9.1/3 {AI05-0229-1} If aspect Independent_Components is specified for a `full_type_declaration`, the declaration shall be that of an array or record type.
- 10./3 {AI05-0229-1} It is illegal to specify either of the aspects Atomic or Atomic_Components to have the value True for an object or type if the implementation cannot support the indivisible reads and updates required by the aspect (see below).
- 11 It is illegal to specify the Size attribute of an atomic object, the Component_Size attribute for an array type with atomic components, or the layout attributes of an atomic component, in a way that prevents the implementation from performing the required indivisible reads and updates.
- 12./3 {AI05-0142-4} {AI05-0218-1} If an atomic object is passed as a parameter, then the formal parameter shall either have an atomic type or allow pass by copy. If an atomic object is used as an actual for a generic formal object of mode **in out**, then the type of the generic formal object shall be atomic. If the prefix of an `attribute_reference` for an Access attribute denotes an atomic object [(including a component)], then the designated type of the resulting access type shall be atomic. If an atomic type is used as an actual for a generic formal derived type, then the ancestor of the formal type shall be atomic. Corresponding rules apply to volatile objects and types.
- 12.a/3 **Ramification:** {AI05-0142-4} A formal parameter allows pass by copy if it is not **aliased** and it is of a type that allows pass by copy (that is, is not a by-reference type).
- 12.1/3 {AI05-0218-1} If a volatile type is used as an actual for a generic formal array type, then the element type of the formal type shall be volatile.
- 13./3 {AI05-0229-1} If an aspect Volatile, Volatile_Components, Atomic, or Atomic_Components is directly specified to have the value True for a stand-alone constant object, then the aspect Import shall also be specified as True for it.
- 13.a **Ramification:** Hence, no initialization expression is allowed for such a constant. Note that a constant that is atomic or volatile because of its type is allowed.
- 13.b **Reason:** Stand-alone constants that are explicitly specified as Atomic or Volatile only make sense if they are being manipulated outside the Ada program. From the Ada perspective the object is read-only. Nevertheless, if imported and

atomic or volatile, the implementation should presume it might be altered externally. For an imported stand-alone constant that is not atomic or volatile, the implementation can assume that it will not be altered.

To be honest: *{AI05-0218-1}* Volatile_Components and Atomic_Components actually are aspects of the anonymous array type; this rule only applies when the aspect is specified directly on the constant object and not when the (named) array type has the aspect. 13.c/3

{AI05-0009-1} *{AI05-0229-1}* It is illegal to specify the aspect Independent or Independent_Components as True for a component, object or type if the implementation cannot provide the independent addressability required by the aspect (see 9.10). 13.1/3

{AI05-0009-1} *{AI05-0229-1}* It is illegal to specify a representation aspect for a component, object or type for which the aspect Independent or Independent_Components is True, in a way that prevents the implementation from providing the independent addressability required by the aspect. 13.2/3

Paragraph 14 was moved to Annex J, “Obsolescent Features”.

Dynamic Semantics

For an atomic object (including an atomic component) all reads and updates of the object as a whole are indivisible. 15

{AI05-0117-1} *{AI05-0275-1}* All tasks of the program (on all processors) that read or update volatile variables see the same order of updates to the variables. A use of an atomic variable or other mechanism may be necessary to avoid erroneous execution and to ensure that access to nonatomic volatile variables is sequential (see 9.10). 16/3

Implementation Note: *{AI05-0117-1}* *{AI05-0275-1}* To ensure this, on a multiprocessor, any read or update of an atomic object may require the use of an appropriate memory barrier. 16.a/3

Discussion: *{AI05-0275-1}* From 9.10 it follows that (in non-erroneous programs) accesses to variables, including those shared by multiple tasks, are always sequential. This guarantees that no task will ever see partial updates of any variable. For volatile variables (including atomic variables), the above rule additionally specifies that all tasks see the same order of updates. 16.b/3

{AI05-0275-1} If for a shared variable X , a read of X occurs sequentially after an update of X , then the read will return the updated value if X is volatile or atomic, but may or may not return the updated value if X is nonvolatile. For nonvolatile accesses, a signaling action is needed in order to share the updated value. 16.c/3

{AI05-0275-1} Because accesses to the same atomic variable by different tasks establish a sequential order between the actions of those tasks, implementations may be required to emit memory barriers around such updates or use atomic instructions that imply such barriers. 16.d/3

Two actions are sequential (see 9.10) if each is the read or update of the same atomic object. 17

If a type is atomic or volatile and it is not a by-copy type, then the type is defined to be a by-reference type. If any subcomponent of a type is atomic or volatile, then the type is defined to be a by-reference type. 18

If an actual parameter is atomic or volatile, and the corresponding formal parameter is not, then the parameter is passed by copy. 19

Implementation Note: Note that in the case where such a parameter is normally passed by reference, a copy of the actual will have to be produced at the call-site, and a pointer to the copy passed to the formal parameter. If the actual is atomic, any copying has to use indivisible read on the way in, and indivisible write on the way out. 19.a

Reason: It has to be known at compile time whether an atomic or a volatile parameter is to be passed by copy or by reference. For some types, it is unspecified whether parameters are passed by copy or by reference. The above rules further specify the parameter passing rules involving atomic and volatile types and objects. 19.b

Implementation Requirements

The external effect of a program (see 1.1.3) is defined to include each read and update of a volatile or atomic object. The implementation shall not generate any memory reads or updates of atomic or volatile objects other than those specified by the program. 20

- 20.a **Discussion:** The presumption is that volatile or atomic objects might reside in an “active” part of the address space where each read has a potential side effect, and at the very least might deliver a different value.
- 20.b The rule above and the definition of external effect are intended to prevent (at least) the following incorrect optimizations, where V is a volatile variable:
- 20.c
- X:= V; Y:=V; cannot be allowed to be translated as Y:=V; X:=V;
 - Deleting redundant loads: X:= V; X:= V; shall read the value of V from memory twice.
 - Deleting redundant stores: V:= X; V:= X; shall write into V twice.
 - Extra stores: V:= X+Y; should not translate to something like V:= X; V:= V+Y;
 - Extra loads: X:= V; Y:= X+Z; X:=X+B; should not translate to something like Y:= V+Z; X:= V+B;
 - Reordering of loads from volatile variables: X:= V1; Y:= V2; (whether or not V1 = V2) should not translate to Y:= V2; X:= V1;
 - Reordering of stores to volatile variables: V1:= X; V2:= X; should not translate to V2:=X; V1:= X;
- 21.f
- 21.g
- 21.h
- 21.i
- 21/3 {AI05-0229-1} If the Pack aspect is True for a type any of whose subcomponents are atomic, the implementation shall not pack the atomic subcomponents more tightly than that for which it can support indivisible reads and updates.
- 21.a/3 **Implementation Note:** {AI05-0009-1} Usually, specifying aspect Pack for such a type will be illegal as the Recommended Level of Support cannot be achieved; otherwise, a warning might be appropriate if no packing whatsoever can be achieved.

Implementation Advice

- 22/2 {AI95-00259-01} A load or store of a volatile object whose size is a multiple of System.Storage_Unit and whose alignment is nonzero, should be implemented by accessing exactly the bits of the object and no others.
- 22.a/2 **Implementation Advice:** A load or store of a volatile object whose size is a multiple of System.Storage_Unit and whose alignment is nonzero, should be implemented by accessing exactly the bits of the object and no others.
- 22.b/2 **Reason:** Since any object can be a volatile object, including packed array components and bit-mapped record components, we require the above only when it is reasonable to assume that the machine can avoid accessing bits outside of the object.
- 22.c/2 **Ramification:** This implies that the load or store of a volatile object that meets the above requirement should not be combined with that of any other object, nor should it access any bits not belonging to any other object. This means that the suitability of the implementation for memory-mapped I/O can be determined from its documentation, as any cases where the implementation does not follow Implementation Advice must be documented.
- 23/2 {AI95-00259-01} A load or store of an atomic object should, where possible, be implemented by a single load or store instruction.
- 23.a/2 **Implementation Advice:** A load or store of an atomic object should be implemented by a single load or store instruction.

NOTES

- 24 9 An imported volatile or atomic constant behaves as a constant (i.e. read-only) with respect to other parts of the Ada program, but can still be modified by an “external source.”

Incompatibilities With Ada 83

- 24.a Pragma Atomic replaces Ada 83's pragma Shared. The name “Shared” was confusing, because the pragma was not used to mark variables as shared.

Wording Changes from Ada 95

- 24.b/2 {AI95-00259-01} Added Implementation Advice to clarify the meaning of Atomic and Volatile in machine terms. The documentation that this advice applies will make the use of Ada implementations more predictable for low-level (such as device register) programming.
- 24.c/2 {AI95-00272-01} Added wording to clarify that a slice of an object of an atomic type is not atomic, just like a component of an atomic type is not (necessarily) atomic.

Incompatibilities With Ada 2005

{AI05-0218-1} **Correction:** Plugged a hole involving volatile components of formal types when the formal type's component has a nonvolatile type. This was done by making certain actual types illegal for formal derived and formal array types; these types were allowed for Ada 95 and Ada 2005. 24.d/3

Extensions to Ada 2005

{AI05-0009-1} {AI05-0229-1} Aspects Independent and Independent_Components are new; they eliminate ambiguity about independent addressability. 24.e/3

{AI05-0229-1} Aspects Atomic, Atomic_Components, Volatile, and Volatile_Components are new; pragmas Atomic, Atomic_Components, Volatile, and Volatile_Components are now obsolescent. 24.f/3

Wording Changes from Ada 2005

{AI05-0117-1} {AI05-0275-1} Revised the definition of volatile to eliminate overspecification and simply focus on the root requirement (that all tasks see the same view of volatile objects). This is not an inconsistency; "memory" arguably includes on-chip caches so long as those are kept consistent. Moreover, it is difficult to imagine a program that could tell the difference. 24.g/3

{AI05-0142-4} Added wording to take explicitly aliased parameters (see 6.1) into account when determining the legality of parameter passing of volatile and atomic objects. 24.h/3

C.7 Task Information

{AI95-00266-02} {AI05-0299-1} [This subclause describes operations and attributes that can be used to obtain the identity of a task. In addition, a package that associates user-defined information with a task is defined. Finally, a package that associates termination procedures with a task or set of tasks is defined.] 1/3

Wording Changes from Ada 95

{AI95-00266-02} {AI05-0299-1} The title and text here were updated to reflect the addition of task termination procedures to this subclause. 1.a/3

C.7.1 The Package Task_Identification

Static Semantics

The following language-defined library package exists:

```
{AI95-00362-01} package Ada.Task_Identification is
  pragma Preelaborate(Task_Identification);
  type Task_Id is private;
  pragma Preelaborable_Initialization (Task_Id);
  Null_Task_Id : constant Task_Id;
  function "=" (Left, Right : Task_Id) return Boolean;

{8652/0070} {AI95-00101-01} {AI05-0189-1} function Image (T : Task_Id) return String;
  function Current_Task return Task_Id;
  function Environment_Task return Task_Id;
  procedure Abort_Task (T : in Task_Id);

{AI05-0189-1} function Is_Terminated (T : Task_Id) return Boolean;
  function Is_Callable (T : Task_Id) return Boolean;
  function Activation_Is_Complete (T : Task_Id) return Boolean;
private
  ... -- not specified by the language
end Ada.Task_Identification;
```

Dynamic Semantics

A value of the type Task_Id identifies an existent task. The constant Null_Task_Id does not identify any task. Each object of the type Task_Id is default initialized to the value of Null_Task_Id. 5

- 6 The function "=" returns True if and only if Left and Right identify the same task or both have the value Null_Task_Id.
- 7 The function Image returns an implementation-defined string that identifies T. If T equals Null_Task_Id, Image returns an empty string.
- 7.a **Implementation defined:** The result of the Task_Identification.Image attribute.
- 8 The function Current_Task returns a value that identifies the calling task.
- 8.1/3 {AI05-0189-1} The function Environment_Task returns a value that identifies the environment task.
- 9 The effect of Abort_Task is the same as the **abort_statement** for the task identified by T. [In addition, if T identifies the environment task, the entire partition is aborted, See E.1.]
- 10 The functions Is_Terminated and Is_Callable return the value of the corresponding attribute of the task identified by T.
- 10.a.1/1 **Ramification:** {8652/0115} {AI95-00206-01} These routines can be called with an argument identifying the environment task. Is_Terminated will always be False for such a call, but Is_Callable (usually True) could be False if the environment task is waiting for the termination of dependent tasks. Thus, a dependent task can use Is_Callable to determine if the main subprogram has completed.
- 10.1/3 {AI05-0189-1} The function Activation_Is_Complete returns True if the task identified by T has completed its activation (whether successfully or not). It returns False otherwise. If T identifies the environment task, Activation_Is_Complete returns True after the elaboration of the **library_items** of the partition has completed.
- 11 For a prefix T that is of a task type [(after any implicit dereference)], the following attribute is defined:
- 12 T'Identity Yields a value of the type Task_Id that identifies the task denoted by T.
- 13 For a prefix E that denotes an **entry_declaration**, the following attribute is defined:
- 14/3 E'Caller {AI05-0262-1} Yields a value of the type Task_Id that identifies the task whose call is now being serviced. Use of this attribute is allowed only inside an **accept_statement**, or **entry_body** after the **entry_barrier**, corresponding to the **entry_declaration** denoted by E.
- 15 Program_Error is raised if a value of Null_Task_Id is passed as a parameter to Abort_Task, Is_Terminated, and Is_Callable.
- 16 Abort_Task is a potentially blocking operation (see 9.5.1).

Bounded (Run-Time) Errors

- 17/3 {AI95-00237-01} {AI05-0004-1} It is a bounded error to call the Current_Task function from an **entry_body**, interrupt handler, or finalization of a task attribute. Program_Error is raised, or an implementation-defined value of the type Task_Id is returned.
- 17.a/2 **Implementation defined:** The value of Current_Task when in a protected entry, interrupt handler, or finalization of a task attribute.
- 17.b **Implementation Note:** This value could be Null_Task_Id, or the ID of some user task, or that of an internal task created by the implementation.
- 17.c/2 **Ramification:** {AI95-00237-01} An entry barrier is syntactically part of an **entry_body**, so a call to Current_Task from an entry barrier is also covered by this rule.

Erroneous Execution

- 18 If a value of Task_Id is passed as a parameter to any of the operations declared in this package (or any language-defined child of this package), and the corresponding task object no longer exists, the execution of the program is erroneous.

Documentation Requirements

The implementation shall document the effect of calling `Current_Task` from an entry body or interrupt handler. 19

This paragraph was deleted. 19.a/2

Documentation Requirement: The effect of calling `Current_Task` from an entry body or interrupt handler. 19.b/2

NOTES

10 This package is intended for use in writing user-defined task scheduling packages and constructing server tasks. `Current_Task` can be used in conjunction with other operations requiring a task as an argument such as `Set_Priority` (see D.5). 20

11 The function `Current_Task` and the attribute `Caller` can return a `Task_Id` value that identifies the environment task. 21

Extensions to Ada 95

{AI95-00362-01} `Task_Identification` is now preelaborated, so it can be used in preelaborated units. 21.a/2

Wording Changes from Ada 95

{8652/0070} {AI95-00101-01} **Corrigendum:** Corrected the mode of the parameter to `Abort_Task` to **in**. 21.b/2

{AI95-00237-01} Corrected the wording to include finalization of a task attribute in the bounded error case; we don't want to specify which task does these operations. 21.c/2

Incompatibilities With Ada 2005

{AI05-0189-1} Functions `Environment_Task` and `Activation_Is_Complete` are added to `Task_Identification`. If `Task_Identification` is referenced in a `use_clause`, and an entity *E* with a `defining_identifier` of `Environment_Task` or `Activation_Is_Complete` is defined in a package that is also referenced in a `use_clause`, the entity *E* may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur. 21.d/3

C.7.2 The Package `Task_Attributes`

Static Semantics

The following language-defined generic library package exists: 1

```

with Ada.Task_Identification; use Ada.Task_Identification; 2
generic
  type Attribute is private;
  Initial_Value : in Attribute;
package Ada.Task_Attributes is
  type Attribute_Handle is access all Attribute; 3
  function Value(T : Task_Id := Current_Task) 4
    return Attribute;
  function Reference(T : Task_Id := Current_Task) 5
    return Attribute_Handle;
  procedure Set_Value(Val : in Attribute; 6
    T : in Task_Id := Current_Task);
  procedure Reinitialize(T : in Task_Id := Current_Task);
end Ada.Task_Attributes; 7

```

Dynamic Semantics

When an instance of `Task_Attributes` is elaborated in a given active partition, an object of the actual type corresponding to the formal type `Attribute` is implicitly created for each task (of that partition) that exists and is not yet terminated. This object acts as a user-defined attribute of the task. A task created previously in the partition and not yet terminated has this attribute from that point on. Each task subsequently created in the partition will have this attribute when created. In all these cases, the initial value of the given attribute is `Initial_Value`. 8

- 9 The Value operation returns the value of the corresponding attribute of T.
- 10 The Reference operation returns an access value that designates the corresponding attribute of T.
- 11 The Set_Value operation performs any finalization on the old value of the attribute of T and assigns Val to that attribute (see 5.2 and 7.6).
- 12 The effect of the Reinitialize operation is the same as Set_Value where the Val parameter is replaced with Initial_Value.

12.a **Implementation Note:** In most cases, the attribute memory can be reclaimed at this point.

- 13 For all the operations declared in this package, Tasking_Error is raised if the task identified by T is terminated. Program_Error is raised if the value of T is Null_Task_Id.

13.1/2 {AI95-00237-01} After a task has terminated, all of its attributes are finalized, unless they have been finalized earlier. When the master of an instantiation of Ada.Task_Attributes is finalized, the corresponding attribute of each task is finalized, unless it has been finalized earlier.

13.a/2 **Reason:** This is necessary so that a task attribute does not outlive its type. For instance, that's possible if the instantiation is nested, and the attribute is on a library-level task.

13.b/2 **Ramification:** The task owning an attribute cannot, in general, finalize that attribute. That's because the attributes are finalized *after* the task is terminated; moreover, a task may have attributes as soon as it is created; the task may never even have been activated.

Bounded (Run-Time) Errors

13.2/1 {8652/0071} {AI95-00165-01} If the package Ada.Task_Attributes is instantiated with a controlled type and the controlled type has user-defined Adjust or Finalize operations that in turn access task attributes by any of the above operations, then a call of Set_Value of the instantiated package constitutes a bounded error. The call may perform as expected or may result in forever blocking the calling task and subsequently some or all tasks of the partition.

Erroneous Execution

- 14 It is erroneous to dereference the access value returned by a given call on Reference after a subsequent call on Reinitialize for the same task attribute, or after the associated task terminates.

14.a **Reason:** This allows the storage to be reclaimed for the object associated with an attribute upon Reinitialize or task termination.

- 15 If a value of Task_Id is passed as a parameter to any of the operations declared in this package and the corresponding task object no longer exists, the execution of the program is erroneous.

15.1/2 {8652/0071} {AI95-00165-01} {AI95-00237-01} An access to a task attribute via a value of type Attribute_Handle is erroneous if executed concurrently with another such access or a call of any of the operations declared in package Task_Attributes. An access to a task attribute is erroneous if executed concurrently with or after the finalization of the task attribute.

15.a.1/1 **Reason:** There is no requirement of atomicity on accesses via a value of type Attribute_Handle.

15.a.2/2 **Ramification:** A task attribute can only be accessed after finalization through a value of type Attribute_Handle. Operations in package Task_Attributes cannot be used to access a task attribute after finalization, because either the master of the instance has been or is in the process of being left (in which case the instance is out of scope and thus cannot be called), or the associated task is already terminated (in which case Tasking_Error is raised for any attempt to call a task attribute operation).

Implementation Requirements

16/1 {8652/0071} {AI95-00165-01} For a given attribute of a given task, the implementation shall perform the operations declared in this package atomically with respect to any of these operations of the same

attribute of the same task. The granularity of any locking mechanism necessary to achieve such atomicity is implementation defined.

Implementation defined: Granularity of locking for Task_Attributes. 16.a.1/1

Ramification: Hence, other than by dereferencing an access value returned by Reference, an attribute of a given task can be safely read and updated concurrently by multiple tasks. 16.a

{AI95-00237-01} After task attributes are finalized, the implementation shall reclaim any storage associated with the attributes. 17/2

Documentation Requirements

The implementation shall document the limit on the number of attributes per task, if any, and the limit on the total storage for attribute values per task, if such a limit exists. 18

In addition, if these limits can be configured, the implementation shall document how to configure them. 19

This paragraph was deleted. 19.a/2

Documentation Requirement: For package Task_Attributes, limits on the number and size of task attributes, and how to configure any limits. 19.b/2

Metrics

{AI95-00434-01} The implementation shall document the following metrics: A task calling the following subprograms shall execute at a sufficiently high priority as to not be preempted during the measurement period. This period shall start just before issuing the call and end just after the call completes. If the attributes of task T are accessed by the measurement tests, no other task shall access attributes of that task during the measurement period. For all measurements described here, the Attribute type shall be a scalar type whose size is equal to the size of the predefined type Integer. For each measurement, two cases shall be documented: one where the accessed attributes are of the calling task [(that is, the default value for the T parameter is used)], and the other, where T identifies another, nonterminated, task. 20/2

The following calls (to subprograms in the Task_Attributes package) shall be measured: 21

- a call to Value, where the return value is Initial_Value; 22
- a call to Value, where the return value is not equal to Initial_Value; 23
- a call to Reference, where the return value designates a value equal to Initial_Value; 24
- a call to Reference, where the return value designates a value not equal to Initial_Value; 25
- {AI95-00434-01} a call to Set_Value where the Val parameter is not equal to Initial_Value and the old attribute value is equal to Initial_Value; 26/2
- a call to Set_Value where the Val parameter is not equal to Initial_Value and the old attribute value is not equal to Initial_Value. 27

Documentation Requirement: The metrics for the Task_Attributes package. 27.a/2

Implementation Permissions

An implementation need not actually create the object corresponding to a task attribute until its value is set to something other than that of Initial_Value, or until Reference is called for the task attribute. Similarly, when the value of the attribute is to be reinitialized to that of Initial_Value, the object may instead be finalized and its storage reclaimed, to be recreated when needed later. While the object does not exist, the function Value may simply return Initial_Value, rather than implicitly creating the object. 28

Discussion: The effect of this permission can only be observed if the assignment operation for the corresponding type has side effects. 28.a

28.b/2 **Implementation Note:** *{AI95-00114-01}* This permission means that even though every task has every attribute, storage need only be allocated for those attributes for which function Reference has been invoked or set to a value other than that of Initial_Value.

29 An implementation is allowed to place restrictions on the maximum number of attributes a task may have, the maximum size of each attribute, and the total storage size allocated for all the attributes of a task.

Implementation Advice

30./2 *{AI95-00434-01}* Some implementations are targeted to domains in which memory use at run time must be completely deterministic. For such implementations, it is recommended that the storage for task attributes will be pre-allocated statically and not from the heap. This can be accomplished by either placing restrictions on the number and the size of the attributes of a task, or by using the pre-allocated storage for the first N attribute objects, and the heap for the others. In the latter case, N should be documented.

30.a/2 **Implementation Advice:** If the target domain requires deterministic memory use at run time, storage for task attributes should be pre-allocated statically and the number of attributes pre-allocated should be documented.

30.b/2 **Discussion:** We don't mention "restrictions on the size and number" (that is, limits) in the text for the Annex, because it is covered by the Documentation Requirement above, and we try not to repeat requirements in the Annex (they're enough work to meet without having to do things twice).

30.1/2 *{AI95-00237-01}* Finalization of task attributes and reclamation of associated storage should be performed as soon as possible after task termination.

30.c/2 **Implementation Advice:** Finalization of task attributes and reclamation of associated storage should be performed as soon as possible after task termination.

30.d/2 **Reason:** *{AI95-00237-01}* This is necessary because the normative wording only says that attributes are finalized "after" task termination. Without this advice, waiting until the instance is finalized would meet the requirements (it is after termination, but may be a very long time after termination). We can't say anything more specific than this, as we do not want to require the overhead of an interaction with the tasking system to be done at a specific point.

NOTES

31 12 An attribute always exists (after instantiation), and has the initial value. It need not occupy memory until the first operation that potentially changes the attribute value. The same holds true after Reinitialize.

32 13 The result of the Reference function should be used with care; it is always safe to use that result in the task body whose attribute is being accessed. However, when the result is being used by another task, the programmer must make sure that the task whose attribute is being accessed is not yet terminated. Failing to do so could make the program execution erroneous.

Wording Changes from Ada 95

33.a/2 *{8652/0071}* *{AI95-00165-01}* **Corrigendum:** Clarified that use of task attribute operations from within a task attribute operation (by an Adjust or Finalize call) is a bounded error, and that concurrent use of attribute handles is erroneous.

33.b/2 *{AI95-00237-01}* Clarified the wording so that the finalization takes place after the termination of the task or when the instance is finalized (whichever is sooner).

C.7.3 The Package Task_Termination

Static Semantics

1/2 *{AI95-00266-02}* The following language-defined library package exists:

```
2/2   with Ada.Task_Identification;
      with Ada.Exceptions;
      package Ada.Task_Termination is
        pragma Preelaborate(Task_Termination);
3/2   type Cause_Of_Termination is (Normal, Abnormal, Unhandled_Exception);
4/2   type Termination_Handler is access protected procedure
      (Cause : in Cause_Of_Termination;
       T      : in Ada.Task_Identification.Task_Id;
       X      : in Ada.Exceptions.Exception_Occurrence);
```

```

procedure Set_Dependents_Fallback_Handler 5/2
  (Handler: in Termination_Handler);
function Current_Task_Fallback_Handler return Termination_Handler;

procedure Set_Specific_Handler 6/2
  (T      : in Ada.Task_Identification.Task_Id;
   Handler : in Termination_Handler);
function Specific_Handler (T : Ada.Task_Identification.Task_Id)
  return Termination_Handler;

end Ada.Task_Termination; 7/2

```

Dynamic Semantics

{AI95-00266-02} {AI05-0202-1} The type `Termination_Handler` identifies a protected procedure to be executed by the implementation when a task terminates. Such a protected procedure is called a *handler*. In all cases T identifies the task that is terminating. If the task terminates due to completing the last statement of its body, or as a result of waiting on a terminate alternative, and the finalization of the task completes normally, then `Cause` is set to `Normal` and `X` is set to `Null_Occurrence`. If the task terminates because it is being aborted, then `Cause` is set to `Abnormal`; `X` is set to `Null_Occurrence` if the finalization of the task completes normally. If the task terminates because of an exception raised by the execution of its `task_body`, then `Cause` is set to `Unhandled_Exception`; `X` is set to the associated exception occurrence if the finalization of the task completes normally. Independent of how the task completes, if finalization of the task propagates an exception, then `Cause` is either `Unhandled_Exception` or `Abnormal`, and `X` is an exception occurrence that identifies the `Program_Error` exception. 8/3

{AI95-00266-02} Each task has two termination handlers, a *fall-back handler* and a *specific handler*. The specific handler applies only to the task itself, while the fall-back handler applies only to the dependent tasks of the task. A handler is said to be *set* if it is associated with a nonnull value of type `Termination_Handler`, and *cleared* otherwise. When a task is created, its specific handler and fall-back handler are cleared. 9/2

{AI95-00266-02} {AI05-0264-1} The procedure `Set_Dependents_Fallback_Handler` changes the fall-back handler for the calling task: if `Handler` is `null`, that fall-back handler is cleared; otherwise, it is set to be `Handler.all`. If a fall-back handler had previously been set it is replaced. 10/3

{AI95-00266-02} {AI05-0264-1} The function `Current_Task_Fallback_Handler` returns the fall-back handler that is currently set for the calling task, if one is set; otherwise, it returns `null`. 11/3

{AI95-00266-02} {AI05-0264-1} The procedure `Set_Specific_Handler` changes the specific handler for the task identified by T: if `Handler` is `null`, that specific handler is cleared; otherwise, it is set to be `Handler.all`. If a specific handler had previously been set it is replaced. 12/3

Ramification: {AI05-0005-1} This package cannot portably be used to set a handler on the program as a whole. It is possible to call `Set_Specific_Handler` with the environment task's ID. But any call to the handler would necessarily be a Bounded (Run-Time) Error, as the handler is called after the task's finalization has completed. In the case of the environment task, that includes any possible protected objects, and calling a protected object after it is finalized is a Bounded (Run-Time) Error (see 9.4). This might work in a particular implementation, but it cannot be depended upon. 12.a/3

{AI95-00266-02} {AI05-0264-1} The function `Specific_Handler` returns the specific handler that is currently set for the task identified by T, if one is set; otherwise, it returns `null`. 13/3

{AI95-00266-02} As part of the finalization of a `task_body`, after performing the actions specified in 7.6 for finalization of a master, the specific handler for the task, if one is set, is executed. If the specific handler is cleared, a search for a fall-back handler proceeds by recursively following the master relationship for the task. If a task is found whose fall-back handler is set, that handler is executed; otherwise, no handler is executed. 14/2

15/2 {AI95-00266-02} For `Set_Specific_Handler` or `Specific_Handler`, `Tasking_Error` is raised if the task identified by `T` has already terminated. `Program_Error` is raised if the value of `T` is `Ada.Task_Identification.Null_Task_Id`.

16/2 {AI95-00266-02} An exception propagated from a handler that is invoked as part of the termination of a task has no effect.

Erroneous Execution

17/2 {AI95-00266-02} For a call of `Set_Specific_Handler` or `Specific_Handler`, if the task identified by `T` no longer exists, the execution of the program is erroneous.

Extensions to Ada 95

17.a/2 {AI95-00266-02} Package `Task_Termination` is new.

Wording Changes from Ada 2005

17.b/3 {AI05-0202-1} **Correction:** Specified what is passed to the handler if the finalization of the task fails after it is completed. This was not specified at all in Ada 2005, so there is a possibility that some program depended on some other behavior of an implementation. But as this case is very unlikely (and only occurs when there is already a significant bug in the program - so should not occur in fielded systems), we're not listing this as an inconsistency.

Annex D

(normative)

Real-Time Systems

This Annex specifies additional characteristics of Ada implementations intended for real-time systems software. To conform to this Annex, an implementation shall also conform to the Systems Programming Annex. 1

Metrics

The metrics are documentation requirements; an implementation shall document the values of the language-defined metrics for at least one configuration [of hardware or an underlying system] supported by the implementation, and shall document the details of that configuration. 2

This paragraph was deleted. 2.a/2

Documentation Requirement: The details of the configuration used to generate the values of all metrics. 2.a.1/2

Reason: The actual values of the metrics are likely to depend on hardware configuration details that are variable and generally outside the control of a compiler vendor. 2.b

The metrics do not necessarily yield a simple number. [For some, a range is more suitable, for others a formula dependent on some parameter is appropriate, and for others, it may be more suitable to break the metric into several cases.] Unless specified otherwise, the metrics in this annex are expressed in processor clock cycles. For metrics that require documentation of an upper bound, if there is no upper bound, the implementation shall report that the metric is unbounded. 3

Discussion: There are several good reasons to specify metrics in seconds; there are however equally good reasons to specify them in processor clock cycles. In defining the metrics, we have tried to strike a balance on a case-by-case basis. 3.a

It has been suggested that all metrics should be given names, so that “data-sheets” could be formulated and published by vendors. However the paragraph number can serve that purpose. 3.b

NOTES

1 The specification of the metrics makes a distinction between upper bounds and simple execution times. Where something is just specified as “the execution time of” a piece of code, this leaves one the freedom to choose a nonpathological case. This kind of metric is of the form “there exists a program such that the value of the metric is V”. Conversely, the meaning of upper bounds is “there is no program such that the value of the metric is greater than V”. This kind of metric can only be partially tested, by finding the value of V for one or more test programs. 4

2 The metrics do not cover the whole language; they are limited to features that are specified in Annex C, “Systems Programming” and in this Annex. The metrics are intended to provide guidance to potential users as to whether a particular implementation of such a feature is going to be adequate for a particular real-time application. As such, the metrics are aimed at known implementation choices that can result in significant performance differences. 5

3 The purpose of the metrics is not necessarily to provide fine-grained quantitative results or to serve as a comparison between different implementations on the same or different platforms. Instead, their goal is rather qualitative; to define a standard set of approximate values that can be measured and used to estimate the general suitability of an implementation, or to evaluate the comparative utility of certain features of an implementation for a particular real-time application. 6

Extensions to Ada 83

This Annex is new to Ada 95. 6.a

D.1 Task Priorities

{AI05-0299-1} [This subclause specifies the priority model for real-time systems. In addition, the methods for specifying priorities are defined.] 1/3

Paragraphs 2 through 6 were moved to Annex J, “Obsolescent Features”.

Static Semantics

- 6.1/3 *{AI05-0229-1}* For a task type (including the anonymous type of a `single_task_declaration`), protected type (including the anonymous type of a `single_protected_declaration`), or subprogram, the following language-defined representation aspects may be specified:
- 6.2/3 **Priority** The aspect `Priority` is an **expression**, which shall be of type `Integer`.
- 6.a/3 **Aspect Description for Priority:** Priority of a task object or type, or priority of a protected object or type; the priority is not in the interrupt range.
- 6.3/3 **Interrupt_Priority**
The aspect `Interrupt_Priority` is an **expression**, which shall be of type `Integer`.
- 6.b/3 **Aspect Description for Interrupt_Priority:** Priority of a task object or type, or priority of a protected object or type; the priority is in the interrupt range.

Legality Rules

- 7/3 *This paragraph was deleted. {AI05-0229-1}*
- 8/3 *{AI05-0229-1}* If the `Priority` aspect is specified for a subprogram, the **expression** shall be static, and its value shall be in the range of `System.Priority`.
- 8.a **Reason:** This value is needed before it gets elaborated, when the environment task starts executing.
- 8.1/3 *{AI05-0229-1}* At most one of the `Priority` and `Interrupt_Priority` aspects may be specified for a given entity.
- 8.b/3 **Ramification:** This includes specifying via pragmas (see J.15.11). Note that 13.1 prevents multiple specifications of a single representation aspect by any means.
- 8.2/3 *{AI05-0229-1}* Neither of the `Priority` or `Interrupt_Priority` aspects shall be specified for a synchronized interface type.

Static Semantics

- 9 The following declarations exist in package `System`:
- 10 **subtype** `Any_Priority` **is** `Integer` **range** *implementation-defined*;
subtype `Priority` **is** `Any_Priority`
range `Any_Priority'First .. implementation-defined`;
subtype `Interrupt_Priority` **is** `Any_Priority`
range `Priority'Last+1 .. Any_Priority'Last`;
- 11 `Default_Priority` : **constant** `Priority` := $(\text{Priority}'\text{First} + \text{Priority}'\text{Last})/2$;
- 11.a **Implementation defined:** The declarations of `Any_Priority` and `Priority`.
- 12 The full range of priority values supported by an implementation is specified by the subtype `Any_Priority`. The subrange of priority values that are high enough to require the blocking of one or more interrupts is specified by the subtype `Interrupt_Priority`. [The subrange of priority values below `System.-Interrupt_Priority'First` is specified by the subtype `System.Priority`.]

13/3 *This paragraph was deleted. {AI05-0229-1}*

Dynamic Semantics

- 14/3 *{AI05-0229-1}* The `Priority` aspect has no effect if it is specified for a subprogram other than the main subprogram; the `Priority` value is not associated with any task.
- 15 A *task priority* is an integer value that indicates a degree of urgency and is the basis for resolving competing demands of tasks for resources. Unless otherwise specified, whenever tasks compete for processors or other implementation-defined resources, the resources are allocated to the task with the highest priority value. The *base priority* of a task is the priority with which it was created, or to which it was later set by `Dynamic_Priorities.Set_Priority` (see D.5). At all times, a task also has an *active priority*,

which generally reflects its base priority as well as any priority it inherits from other sources. *Priority inheritance* is the process by which the priority of a task or other entity (e.g. a protected object; see D.3) is used in the evaluation of another task's active priority.

- Implementation defined:** Implementation-defined execution resources. 15.a
- {AI05-0229-1} The effect of specifying a Priority or Interrupt_Priority aspect for a protected type or single_protected_declaration is discussed in D.3. 16/3
- {AI05-0229-1} The expression specified for the Priority or Interrupt_Priority aspect of a task is evaluated for each task object (see 9.1). For the Priority aspect, the value of the expression is converted to the subtype Priority; for the Interrupt_Priority aspect, this value is converted to the subtype Any_Priority. The priority value is then associated with the task object whose task declaration specifies the aspect. 17/3
- {AI05-0229-1} Likewise, the priority value is associated with the environment task if the aspect is specified for the main subprogram. 18/3
- {AI05-0229-1} The initial value of a task's base priority is specified by default or by means of a Priority or Interrupt_Priority aspect. [After a task is created, its base priority can be changed only by a call to Dynamic_Priorities.Set_Priority (see D.5).] The initial base priority of a task in the absence of an aspect is the base priority of the task that creates it at the time of creation (see 9.1). If the aspect Priority is not specified for the main subprogram, the initial base priority of the environment task is System.Default_Priority. [The task's active priority is used when the task competes for processors. Similarly, the task's active priority is used to determine the task's position in any queue when Priority_Queueing is specified (see D.4).] 19/3
- {AI95-00357-01} At any time, the active priority of a task is the maximum of all the priorities the task is inheriting at that instant. For a task that is not held (see D.11), its base priority is a source of priority inheritance unless otherwise specified for a particular task dispatching policy. Other sources of priority inheritance are specified under the following conditions: 20/2
- Discussion:** Other parts of the annex, e.g. D.11, define other sources of priority inheritance. 20.a
- {8652/0072} {AI95-00092-01} During activation, a task being activated inherits the active priority that its activator (see 9.2) had at the time the activation was initiated. 21/1
 - {8652/0072} {AI95-00092-01} During rendezvous, the task accepting the entry call inherits the priority of the entry call (see 9.5.3 and D.4). 22/1
 - During a protected action on a protected object, a task inherits the ceiling priority of the protected object (see 9.5 and D.3). 23
- In all of these cases, the priority ceases to be inherited as soon as the condition calling for the inheritance no longer exists. 24

Implementation Requirements

The range of System.Interrupt_Priority shall include at least one value. 25

The range of System.Priority shall include at least 30 values. 26

NOTES

- 4 The priority expression can include references to discriminants of the enclosing type. 27
- 5 It is a consequence of the active priority rules that at the point when a task stops inheriting a priority from another source, its active priority is re-evaluated. This is in addition to other instances described in this Annex for such re-evaluation. 28
- 6 {AI05-0248-1} An implementation may provide a nonstandard mode in which tasks inherit priorities under conditions other than those specified above. 29/3

- 29.a/3 **Ramification:** {AI05-0229-1} The use of a Priority or Interrupt_Priority aspect does not require the package System to be named in a with_clause for the enclosing compilation_unit.

Extensions to Ada 83

- 29.b The priority of a task is per-object and not per-type.
 29.c Priorities need not be static anymore (except for the main subprogram).

Wording Changes from Ada 83

- 29.d The description of the Priority pragma has been moved to this annex.

Wording Changes from Ada 95

- 29.e/2 {8652/0072} {AI95-00092-01} **Corrigendum:** Clarified that dynamic priority changes are not transitive - that is, they don't apply to tasks that are being activated by or in rendezvous with the task that had its priority changed.
 29.f/2 {AI95-00357-01} Generalized the definition of priority inheritance to take into account the differences between the existing and new dispatching policies.

Extensions to Ada 2005

- 29.g/3 {AI05-0229-1} Aspects Priority and Interrupt_Priority are new; pragmas Priority and Interrupt_Priority are now obsolescent.

D.2 Priority Scheduling

- 1/3 {AI95-00321-01} {AI05-0299-1} [This subclause describes the rules that determine which task is selected for execution when more than one task is ready (see 9).]

Wording Changes from Ada 95

- 1.a/3 {AI95-00321-01} {AI05-0299-1} This introduction is simplified in order to reflect the rearrangement and expansion of this subclause.

D.2.1 The Task Dispatching Model

- 1/2 {AI95-00321-01} [The task dispatching model specifies task scheduling, based on conceptual priority-ordered ready queues.]

Static Semantics

- 1.1/2 {AI95-00355-01} The following language-defined library package exists:

- 1.2/3 {AI05-0166-1} **package** Ada.Dispatching **is**
 pragma Preelaborate(Dispatching);
 1.3/3 {AI05-0166-1} **procedure** Yield;
 1.4/3 {AI05-0166-1} Dispatching_Policy_Error : **exception**;
 end Ada.Dispatching;

- 1.5/2 Dispatching serves as the parent of other language-defined library units concerned with task dispatching.

Dynamic Semantics

- 2/2 {AI95-00321-01} A task can become a *running task* only if it is ready (see 9) and the execution resources required by that task are available. Processors are allocated to tasks based on each task's active priority.
 3 It is implementation defined whether, on a multiprocessor, a task that is waiting for access to a protected object keeps its processor busy.
 3.a **Implementation defined:** Whether, on a multiprocessor, a task that is waiting for access to a protected object keeps its processor busy.

<i>{AI95-00321-01}</i> <i>Task dispatching</i> is the process by which one ready task is selected for execution on a processor. This selection is done at certain points during the execution of a task called <i>task dispatching points</i> . A task reaches a task dispatching point whenever it becomes blocked, and when it terminates. [Other task dispatching points are defined throughout this Annex for specific policies.]	4/2
Ramification: On multiprocessor systems, more than one task can be chosen, at the same time, for execution on more than one processor, as explained below.	4.a
<i>{AI95-00321-01}</i> <i>Task dispatching policies</i> are specified in terms of conceptual <i>ready queues</i> and task states. A ready queue is an ordered list of ready tasks. The first position in a queue is called the <i>head of the queue</i> , and the last position is called the <i>tail of the queue</i> . A task is <i>ready</i> if it is in a ready queue, or if it is running. Each processor has one ready queue for each priority value. At any instant, each ready queue of a processor contains exactly the set of tasks of that priority that are ready for execution on that processor, but are not running on any processor; that is, those tasks that are ready, are not running on any processor, and can be executed using that processor and other available resources. A task can be on the ready queues of more than one processor.	5/2
Discussion: The core language defines a ready task as one that is not blocked. Here we refine this definition and talk about ready queues.	5.a
<i>{AI95-00321-01}</i> Each processor also has one <i>running task</i> , which is the task currently being executed by that processor. Whenever a task running on a processor reaches a task dispatching point it goes back to one or more ready queues; a task (possibly the same task) is then selected to run on that processor. The task selected is the one at the head of the highest priority nonempty ready queue; this task is then removed from all ready queues to which it belongs.	6/2
Discussion: There is always at least one task to run, if we count the idle task.	6.a
<i>{AI95-00321-01}</i> <i>{AI05-0166-1}</i> A call of <code>Yield</code> is a task dispatching point. <code>Yield</code> is a potentially blocking operation (see 9.5.1).	7/3
<i>This paragraph was deleted.</i>	7.a/2
<i>This paragraph was deleted.</i> <i>{AI95-00321-01}</i>	8/2
<i>This paragraph was deleted.</i>	8.a/2
<i>Implementation Permissions</i>	
<i>{AI95-00321-01}</i> An implementation is allowed to define additional resources as execution resources, and to define the corresponding allocation policies for them. Such resources may have an implementation-defined effect on task dispatching.	9/2
Implementation defined: The effect of implementation-defined execution resources on task dispatching.	9.a/2
An implementation may place implementation-defined restrictions on tasks whose active priority is in the <code>Interrupt_Priority</code> range.	10
Ramification: <i>{AI05-0229-1}</i> For example, on some operating systems, it might be necessary to disallow them altogether. This permission applies to tasks whose priority is set to interrupt level for any reason: via an aspect, via a call to <code>Dynamic_Priorities.Set_Priority</code> , or via priority inheritance.	10.a/3
<i>{AI95-00321-01}</i> [For optimization purposes,] an implementation may alter the points at which task dispatching occurs, in an implementation-defined manner. However, a <code>delay_statement</code> always corresponds to at least one task dispatching point.	10.1/2
NOTES	
7 <i>{AI05-0299-1}</i> Clause 9 specifies under which circumstances a task becomes ready. The ready state is affected by the rules for task activation and termination, delay statements, and entry calls. When a task is not ready, it is said to be blocked.	11/3
8 An example of a possible implementation-defined execution resource is a page of physical memory, which needs to be loaded with a particular page of virtual memory before a task can continue execution.	12
9 The ready queues are purely conceptual; there is no requirement that such lists physically exist in an implementation.	13

- 14 10 While a task is running, it is not on any ready queue. Any time the task that is running on a processor is added to a ready queue, a new running task is selected for that processor.
- 15 11 In a multiprocessor system, a task can be on the ready queues of more than one processor. At the extreme, if several processors share the same set of ready tasks, the contents of their ready queues is identical, and so they can be viewed as sharing one ready queue, and can be implemented that way. [Thus, the dispatching model covers multiprocessors where dispatching is implemented using a single ready queue, as well as those with separate dispatching domains.]
- 16 12 The priority of a task is determined by rules specified in this subclause, and under D.1, “Task Priorities”, D.3, “Priority Ceiling Locking”, and D.5, “Dynamic Priorities”.
- 17/2 13 {AI95-00321-01} The setting of a task's base priority as a result of a call to Set_Priority does not always take effect immediately when Set_Priority is called. The effect of setting the task's base priority is deferred while the affected task performs a protected action.

Wording Changes from Ada 95

- 17.a/3 {AI95-00321-01} {AI05-0005-1} This description is simplified to describe only the parts of the dispatching model common to all policies. In particular, rules about preemption are moved elsewhere. This makes it easier to add other policies (which might not involve preemption).

Incompatibilities With Ada 2005

- 17.b/3 {AI05-0166-1} Procedure Yield is added to Dispatching. If Dispatching is referenced in a use_clause, and an entity E with a defining_identifier of Yield is defined in a package that is also referenced in a use_clause, the entity E may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur.

D.2.2 Task Dispatching Pragmas

- 1/3 {AI95-00355-01} {AI05-0299-1} [This subclause allows a single task dispatching policy to be defined for all priorities, or the range of priorities to be split into subranges that are assigned individual dispatching policies.]

Syntax

- 2 The form of a pragma Task_Dispatching_Policy is as follows:
- 3 **pragma** Task_Dispatching_Policy(*policy_identifier*);
- 3.1/2 {AI95-00355-01} The form of a pragma Priority_Specific_Dispatching is as follows:
- 3.2/2 **pragma** Priority_Specific_Dispatching (
policy_identifier, *first_priority_expression*, *last_priority_expression*);

Name Resolution Rules

- 3.3/2 {AI95-00355-01} The expected type for *first_priority_expression* and *last_priority_expression* is Integer.

Legality Rules

- 4/2 {AI95-00321-01} {AI95-00355-01} The *policy_identifier* used in a pragma Task_Dispatching_Policy shall be the name of a task dispatching policy.
- 4.a/2 *This paragraph was deleted.*
- 4.1/2 {AI95-00355-01} The *policy_identifier* used in a pragma Priority_Specific_Dispatching shall be the name of a task dispatching policy.
- 4.2/2 {AI95-00355-01} Both *first_priority_expression* and *last_priority_expression* shall be static expressions in the range of System.Any_Priority; *last_priority_expression* shall have a value greater than or equal to *first_priority_expression*.

Static Semantics

- {AI95-00355-01} Pragma `Task_Dispatching_Policy` specifies the single task dispatching policy. 4.3/2
- {AI95-00355-01} Pragma `Priority_Specific_Dispatching` specifies the task dispatching policy for the specified range of priorities. Tasks with base priorities within the range of priorities specified in a `Priority_Specific_Dispatching` pragma have their active priorities determined according to the specified dispatching policy. Tasks with active priorities within the range of priorities specified in a `Priority_Specific_Dispatching` pragma are dispatched according to the specified dispatching policy. 4.4/2
- Reason:** {AI95-00355-01} Each ready queue is managed by exactly one policy. Anything else would be chaos. The ready queue is determined by the active priority. However, how the active priority is calculated is determined by the policy; in order to break out of this circle, we have to say that the active priority is calculated by the method determined by the policy of the base priority. 4.b/2
- {AI95-00355-01} {AI05-0262-1} If a partition contains one or more `Priority_Specific_Dispatching` pragmas, the dispatching policy for priorities not covered by any `Priority_Specific_Dispatching` pragmas is `FIFO_Within_Priorities`. 4.5/3

Post-Compilation Rules

- {AI95-00355-01} A `Task_Dispatching_Policy` pragma is a configuration pragma. A `Priority_Specific_Dispatching` pragma is a configuration pragma. 5/2
- {AI95-00355-01} The priority ranges specified in more than one `Priority_Specific_Dispatching` pragma within the same partition shall not be overlapping. 5.1/2
- {AI95-00355-01} If a partition contains one or more `Priority_Specific_Dispatching` pragmas it shall not contain a `Task_Dispatching_Policy` pragma. 5.2/2
- This paragraph was deleted.* {AI95-00333-01} 6/2

Dynamic Semantics

- {AI95-00355-01} [A *task dispatching policy* specifies the details of task dispatching that are not covered by the basic task dispatching model. These rules govern when tasks are inserted into and deleted from the ready queues.] A single task dispatching policy is specified by a `Task_Dispatching_Policy` pragma. Pragma `Priority_Specific_Dispatching` assigns distinct dispatching policies to subranges of `System.Any_Priority`. 7/2
- {AI95-00355-01} If neither pragma applies to any of the program units comprising a partition, the task dispatching policy for that partition is unspecified. 7.1/2
- {AI95-00355-01} {AI05-0262-1} If a partition contains one or more `Priority_Specific_Dispatching` pragmas, a task dispatching point occurs for the currently running task of a processor whenever there is a nonempty ready queue for that processor with a higher priority than the priority of the running task. 7.2/3
- Discussion:** {AI05-0005-1} If we have priority specific dispatching then we want preemption across the entire range of priorities. That prevents higher priority tasks from being blocked by lower priority tasks that have a different policy. On the other hand, if we have a single policy for the entire partition, we want the characteristics of that policy to apply for preemption; specifically, we might not require any preemption. Note that policy `Non_Preemptive_FIFO_Within_Priorities` is not allowed in a priority specific dispatching pragma. 7.a/3
- {AI95-00355-01} A task that has its base priority changed may move from one dispatching policy to another. It is immediately subject to the new dispatching policy. 7.3/2
- Ramification:** Once subject to the new dispatching policy, it may be immediately preempted or dispatched, according to the rules of the new policy. 7.b/2

Paragraphs 7 through 13 were moved to D.2.3.

Implementation Requirements

- 14.1/2 {AI95-00333-01} {AI95-00355-01} An implementation shall allow, for a single partition, both the locking policy (see D.3) to be specified as Ceiling_Locking and also one or more Priority_Specific_Dispatching pragmas to be given.

Documentation Requirements

Paragraphs 14 through 16 were moved to D.2.3.

- 17.a/2 This paragraph was deleted.

Implementation Permissions

- 18/2 {AI95-00256-01} Implementations are allowed to define other task dispatching policies, but need not support more than one task dispatching policy per partition.
- 19/2 {AI95-00355-01} An implementation need not support pragma Priority_Specific_Dispatching if it is infeasible to support it in the target environment.
- 19.a/2 **Implementation defined:** Implementation defined task dispatching policies.

NOTES

Paragraphs 19 through 21 were deleted.

Extensions to Ada 95

- 22.a/2 {AI95-00333-01} **Amendment Correction:** It is no longer required to specify Ceiling_Locking with the language-defined task dispatching policies; we only require that implementations *allow* them to be used together.
- 22.b/3 {AI95-00355-01} {AI05-0005-1} **Pragma** Priority_Specific_Dispatching is new; it allows the specification of different policies for different priorities.

Wording Changes from Ada 95

- 22.c/2 {AI95-00256-01} Clarified that an implementation need support only one task dispatching policy (of any kind, language-defined or otherwise) per partition.
- 22.d/3 {AI95-00321-01} {AI05-0005-1} This description is simplified to describe only the rules for the Task_Dispatching_Policy pragma that are common to all policies. In particular, rules about preemption are moved elsewhere. This makes it easier to add other policies (which might not involve preemption).

D.2.3 Preemptive Dispatching

- 1/3 {AI95-00321-01} {AI05-0299-1} [This subclause defines a preemptive task dispatching policy.]

Static Semantics

- 2/2 {AI95-00355-01} The *policy_identifier* FIFO_Within_Priorities is a task dispatching policy.

Dynamic Semantics

- 3/2 {AI95-00321-01} When FIFO_Within_Priorities is in effect, modifications to the ready queues occur only as follows:
- 4/2
- {AI95-00321-01} When a blocked task becomes ready, it is added at the tail of the ready queue for its active priority.
- 5/2
- When the active priority of a ready task that is not running changes, or the setting of its base priority takes effect, the task is removed from the ready queue for its old active priority and is added at the tail of the ready queue for its new active priority, except in the case where the active priority is lowered due to the loss of inherited priority, in which case the task is added at the head of the ready queue for its new active priority.

- When the setting of the base priority of a running task takes effect, the task is added to the tail of the ready queue for its active priority. 6/2
- When a task executes a `delay_statement` that does not result in blocking, it is added to the tail of the ready queue for its active priority. 7/2

Ramification: If the delay does result in blocking, the task moves to the “delay queue”, not to the ready queue. 7.a/2
 {AI95-00321-01} Each of the events specified above is a task dispatching point (see D.2.1). 8/2

{AI95-00321-01} A task dispatching point occurs for the currently running task of a processor whenever there is a nonempty ready queue for that processor with a higher priority than the priority of the running task. The currently running task is said to be *preempted* and it is added at the head of the ready queue for its active priority. 9/2

Implementation Requirements

{AI95-00333-01} An implementation shall allow, for a single partition, both the task dispatching policy to be specified as `FIFO_Within_Priorities` and also the locking policy (see D.3) to be specified as `Ceiling_Locking`. 10/2

Reason: This is the preferred combination of the `FIFO_Within_Priorities` policy with a locking policy, and we want that combination to be portable. 10.a/2

Documentation Requirements

{AI95-00321-01} *Priority inversion* is the duration for which a task remains at the head of the highest priority nonempty ready queue while the processor executes a lower priority task. The implementation shall document: 11/2

- The maximum priority inversion a user task can experience due to activity of the implementation (on behalf of lower priority tasks), and 12/2

Documentation Requirement: The maximum priority inversion a user task can experience from the implementation. 12.a/2

- whether execution of a task can be preempted by the implementation processing of delay expirations for lower priority tasks, and if so, for how long. 13/2

Documentation Requirement: The amount of time that a task can be preempted for processing on behalf of lower-priority tasks. 13.a/2

NOTES

14 {AI95-00321-01} If the active priority of a running task is lowered due to loss of inherited priority (as it is on completion of a protected operation) and there is a ready task of the same active priority that is not running, the running task continues to run (provided that there is no higher priority task). 14/2

15 {AI95-00321-01} Setting the base priority of a ready task causes the task to move to the tail of the queue for its active priority, regardless of whether the active priority of the task actually changes. 15/2

Wording Changes from Ada 95

{AI95-00321-01} This subclause is new; it mainly consists of text that was found in D.2.1 and D.2.2 in Ada 95. This was separated out so the definition of additional policies was easier. 15.a/2

{AI95-00333-01} We require that implementations allow this policy and `Ceiling_Locking` together. 15.b/2

{AI95-00355-01} We explicitly defined `FIFO_Within_Priorities` to be a task dispatching policy. 15.c/2

D.2.4 Non-Preemptive Dispatching

{AI95-00298-01} {AI05-0299-1} [This subclause defines a non-preemptive task dispatching policy.] 1/3

Static Semantics

{AI95-00298-01} {AI95-00355-01} The *policy_identifier* `Non_Preemptive_FIFO_Within_Priorities` is a task dispatching policy. 2/2

2.1/3 {AI05-0166-1} The following language-defined library package exists:

```
2.2/3 package Ada.Dispatching.Non_Preemptive is
      pragma Preelaborate(Non_Preemptive);
      procedure Yield_To_Higher;
      procedure Yield_To_Same_Or_Higher renames Yield;
      end Ada.Dispatching.Non_Preemptive;
```

2.3/3 {AI05-0166-1} {AI05-0264-1} A call of `Yield_To_Higher` is a task dispatching point for this policy. If the task at the head of the highest priority ready queue has a higher active priority than the calling task, then the calling task is preempted.

2.a/3 **Ramification:** For language-defined policies other than `Non_Preemptive_FIFO_Within_Priorities`, a higher priority task should never be on a ready queue while a lower priority task is executed. Thus, for such policies, `Yield_To_Higher` does nothing.

2.b/3 `Yield_To_Higher` is *not* a potentially blocking operation; it can be used during a protected operation. That is allowed, as under the predefined `Ceiling_Locking` policy any task with a higher priority than the protected operation cannot call the operation (that would violate the locking policy). An implementation-defined locking policy may need to define the semantics of `Yield_To_Higher` differently.

Legality Rules

3/2 {AI95-00355-01} `Non_Preemptive_FIFO_Within_Priorities` shall not be specified as the *policy_identifier* of `pragma Priority_Specific_Dispatching` (see D.2.2).

3.a/2 **Reason:** The non-preemptive nature of this policy could cause the policies of higher priority tasks to malfunction, missing deadlines and having unlimited priority inversion. That would render the use of such policies impotent and misleading. As such, this policy only makes sense for a complete system.

Dynamic Semantics

4/2 {AI95-00298-01} When `Non_Preemptive_FIFO_Within_Priorities` is in effect, modifications to the ready queues occur only as follows:

- 5/2 • {AI95-00298-01} When a blocked task becomes ready, it is added at the tail of the ready queue for its active priority.
- 6/2 • When the active priority of a ready task that is not running changes, or the setting of its base priority takes effect, the task is removed from the ready queue for its old active priority and is added at the tail of the ready queue for its new active priority.
- 7/2 • When the setting of the base priority of a running task takes effect, the task is added to the tail of the ready queue for its active priority.
- 8/2 • When a task executes a `delay_statement` that does not result in blocking, it is added to the tail of the ready queue for its active priority.

8.a/2 **Ramification:** If the delay does result in blocking, the task moves to the “delay queue”, not to the ready queue.

9/3 {AI05-0166-1} For this policy, blocking or termination of a task, a `delay_statement`, a call to `Yield_To_Higher`, and a call to `Yield_To_Same_Or_Higher` or `Yield` are the only task dispatching points (see D.2.1).

9.a/3 **Ramification:** {AI05-0166-1} A `delay_statement` is always a task dispatching point even if it is not blocking. Similarly, a call to `Yield_To_Higher` is never blocking, but it is a task dispatching point. In each of these cases, they can cause the current task to stop running (it is still ready). Otherwise, the running task continues to run until it is blocked.

Implementation Requirements

10/2 {AI95-00333-01} An implementation shall allow, for a single partition, both the task dispatching policy to be specified as `Non_Preemptive_FIFO_Within_Priorities` and also the locking policy (see D.3) to be specified as `Ceiling_Locking`.

Reason: This is the preferred combination of the `Non_Preemptive_FIFO_Within_Priorities` policy with a locking policy, and we want that combination to be portable. 10.a/2

Implementation Permissions

{AI95-00298-01} {AI05-0229-1} {AI05-0269-1} Since implementations are allowed to round all ceiling priorities in subrange `System.Priority` to `System.Priority'Last` (see D.3), an implementation may allow a task of a partition using the `Non_Preemptive_FIFO_Within_Priorities` policy to execute within a protected object without raising its active priority provided the associated protected unit does not contain any subprograms with aspects `Interrupt_Handler` or `Attach_Handler` specified, nor does the unit have aspect `Interrupt_Priority` specified. When the locking policy (see D.3) is `Ceiling_Locking`, an implementation taking advantage of this permission shall ensure that a call to `Yield_to_Higher` that occurs within a protected action uses the ceiling priority of the protected object (rather than the active priority of the task) when determining whether to preempt the task. 11/3

Reason: {AI05-0269-1} We explicitly require that the ceiling priority be used in calls to `Yield_to_Higher` in order to prevent a risk of priority inversion and consequent loss of mutual exclusion when `Yield_to_Higher` is used in a protected object. This requirement might lessen the value of the permission (as the current `Ceiling_Priority` will have to be maintained in the TCB), but loss of mutual exclusion cannot be tolerated. The primary benefit of the permission (eliminating the need for preemption at the end of a protected action) is still available. As noted above, an implementation-defined locking policy will need to specify the semantics of `Yield_to_Higher`, including this case. 11.a.1/3

Extensions to Ada 95

{AI95-00298-01} {AI95-00355-01} Policy `Non_Preemptive_FIFO_Within_Priorities` is new. 11.a/2

Extensions to Ada 2005

{AI05-0166-1} Package `Dispatching.Non_Preemptive` is new. 11.b/3

D.2.5 Round Robin Dispatching

{AI95-00355-01} {AI05-0299-1} [This subclause defines the task dispatching policy `Round_Robin_Within_Priorities` and the package `Round_Robin`.] 1/3

Static Semantics

{AI95-00355-01} The *policy_identifier* `Round_Robin_Within_Priorities` is a task dispatching policy. 2/2

{AI95-00355-01} The following language-defined library package exists: 3/2

```
with System;
with Ada.Real_Time;
package Ada.Dispatching.Round_Robin is
  Default_Quantum : constant Ada.Real_Time.Time_Span :=
    implementation-defined;
  procedure Set_Quantum (Pri : in System.Priority;
    Quantum : in Ada.Real_Time.Time_Span);
  procedure Set_Quantum (Low, High : in System.Priority;
    Quantum : in Ada.Real_Time.Time_Span);
  function Actual_Quantum (Pri : System.Priority)
    return Ada.Real_Time.Time_Span;
  function Is_Round_Robin (Pri : System.Priority) return Boolean;
end Ada.Dispatching.Round_Robin; 4/2
```

Implementation defined: The value of `Default_Quantum` in `Dispatching.Round_Robin`. 4.a.1/2

{AI95-00355-01} When task dispatching policy `Round_Robin_Within_Priorities` is the single policy in effect for a partition, each task with priority in the range of `System.Interrupt_Priority` is dispatched according to policy `FIFO_Within_Priorities`. 5/2

Dynamic Semantics

- 6/2 {AI95-00355-01} The procedures `Set_Quantum` set the required Quantum value for a single priority level Pri or a range of priority levels Low .. High. If no quantum is set for a Round Robin priority level, `Default_Quantum` is used.
- 7/2 {AI95-00355-01} The function `Actual_Quantum` returns the actual quantum used by the implementation for the priority level Pri.
- 8/3 {AI95-00355-01} {AI05-0264-1} The function `Is_Round_Robin` returns True if priority Pri is covered by task dispatching policy `Round_Robin_Within_Priorities`; otherwise, it returns False.
- 9/2 {AI95-00355-01} A call of `Actual_Quantum` or `Set_Quantum` raises exception `Dispatching.Dispatching_Policy_Error` if a predefined policy other than `Round_Robin_Within_Priorities` applies to the specified priority or any of the priorities in the specified range.
- 10/2 {AI95-00355-01} For `Round_Robin_Within_Priorities`, the dispatching rules for `FIFO_Within_Priorities` apply with the following additional rules:
- 11/2 • When a task is added or moved to the tail of the ready queue for its base priority, it has an execution time budget equal to the quantum for that priority level. This will also occur when a blocked task becomes executable again.
 - 12/2 • When a task is preempted (by a higher priority task) and is added to the head of the ready queue for its priority level, it retains its remaining budget.
 - 13/2 • While a task is executing, its budget is decreased by the amount of execution time it uses. The accuracy of this accounting is the same as that for execution time clocks (see D.14).
- 13.a/2 **Ramification:** Note that this happens even when the task is executing at a higher, inherited priority, and even if that higher priority is dispatched by a different policy than round robin.
- 14/2 • When a task has exhausted its budget and is without an inherited priority (and is not executing within a protected operation), it is moved to the tail of the ready queue for its priority level. This is a task dispatching point.
- 14.a/2 **Ramification:** In this case, it will be given a budget as described in the first bullet.
- 14.b/2 The rules for `FIFO_Within_Priority` (to which these bullets are added) say that a task that has its base priority set to a Round Robin priority is moved to the tail of the ready queue for its new priority level, and then will be given a budget as described in the first bullet. That happens whether or not the task's original base priority was a Round Robin priority.

Implementation Requirements

- 15/2 {AI95-00333-01} {AI95-00355-01} An implementation shall allow, for a single partition, both the task dispatching policy to be specified as `Round_Robin_Within_Priorities` and also the locking policy (see D.3) to be specified as `Ceiling_Locking`.
- 15.a/2 **Reason:** This is the preferred combination of the `Round_Robin_Within_Priorities` policy with a locking policy, and we want that combination to be portable.

Documentation Requirements

- 16/2 {AI95-00355-01} An implementation shall document the quantum values supported.
- 16.a.1/2 **Documentation Requirement:** The quantum values supported for round robin dispatching.
- 17/2 {AI95-00355-01} An implementation shall document the accuracy with which it detects the exhaustion of the budget of a task.
- 17.a.1/2 **Documentation Requirement:** The accuracy of the detection of the exhaustion of the budget of a task for round robin dispatching.

NOTES

- 16 {AI95-00355-01} Due to implementation constraints, the quantum value returned by Actual_Quantum might not be identical to that set with Set_Quantum. 18/2
- 17 {AI95-00355-01} A task that executes continuously with an inherited priority will not be subject to round robin dispatching. 19/2

Extensions to Ada 95

- {AI95-00355-01} Policy Round_Robin_Within_Priorities and package Dispatching.Round_Robin are new. 19.a/2

D.2.6 Earliest Deadline First Dispatching

{AI95-00357-01} The deadline of a task is an indication of the urgency of the task; it represents a point on an ideal physical time line. The deadline might affect how resources are allocated to the task. 1/2

{AI95-00357-01} {AI05-0229-1} {AI05-0299-1} This subclause defines a package for representing the deadline of a task and a dispatching policy that defines Earliest Deadline First (EDF) dispatching. An aspect is defined to assign an initial deadline to a task. 2/3

Discussion: {AI05-0229-1} This aspect is the only way of assigning an initial deadline to a task so that its activation can be controlled by EDF scheduling. This is similar to the way aspect Priority is used to give an initial priority to a task. 2.a/3

Language Design Principles

{AI95-00357-01} {AI05-0299-1} To predict the behavior of a multi-tasking program it is necessary to control access to the processor which is preemptive, and shared objects which are usually non-preemptive and embodied in protected objects. Two common dispatching policies for the processor are fixed priority and EDF. The most effective control over shared objects is via preemption levels. With a pure priority scheme a single notion of priority is used for processor dispatching and preemption levels. With EDF and similar schemes priority is used for preemption levels (only), with another measure used for dispatching. T.P. Baker showed (*Real-Time Systems*, March 1991, vol. 3, num. 1, *Stack-Based Scheduling of Realtime Processes*) that for EDF a newly released task should only preempt the currently running task if it has an earlier deadline and a higher preemption level than any currently “locked” protected object. The rules of this subclause implement this scheme including the case where the newly released task should execute before some existing tasks but not preempt the currently executing task. 2.b/3

Paragraphs 3 through 6 were moved to Annex J, “Obsolescent Features”.

Static Semantics

{AI95-00357-01} The *policy_identifier* EDF_Across_Priorities is a task dispatching policy. 7/2

{AI95-00357-01} The following language-defined library package exists: 8/2

```
with Ada.Real_Time;
with Ada.Task_Identification;
package Ada.Dispatching.EDF is
  subtype Deadline is Ada.Real_Time.Time;
  Default_Deadline : constant Deadline :=
    Ada.Real_Time.Time_Last;
  procedure Set_Deadline (D : in Deadline;
    T : in Ada.Task_Identification.Task_Id :=
    Ada.Task_Identification.Current_Task);
  procedure Delay_Until_And_Set_Deadline (
    Delay_Until_Time : in Ada.Real_Time.Time;
    Deadline_Offset : in Ada.Real_Time.Time_Span);
  function Get_Deadline (T : Ada.Task_Identification.Task_Id :=
    Ada.Task_Identification.Current_Task) return Deadline;
end Ada.Dispatching.EDF; 9/2
```

{AI05-0229-1} For a task type (including the anonymous type of a *single_task_declaration*) or subprogram, the following language-defined representation aspect may be specified: 9.1/3

9.2/3 **Relative_Deadline**
 The aspect `Relative_Deadline` is an expression, which shall be of type `Real_Time.Time_Span`.

9.a/3 **Aspect Description for Relative_Deadline:** Task parameter used in Earliest Deadline First Dispatching.

Legality Rules

9.3/3 {AI05-0229-1} The `Relative_Deadline` aspect shall not be specified on a task interface type.

Post-Compilation Rules

10/2 {AI95-00357-01} If the `EDF_Across_Priorities` policy is specified for a partition, then the `Ceiling_Locking` policy (see D.3) shall also be specified for the partition.

11/2 {AI95-00357-01} If the `EDF_Across_Priorities` policy appears in a `Priority_Specific_Dispatching` pragma (see D.2.2) in a partition, then the `Ceiling_Locking` policy (see D.3) shall also be specified for the partition.

11.a/2 **Reason:** Unlike the other language-defined dispatching policies, the semantic description of `EDF_Across_Priorities` assumes `Ceiling_Locking` (and a ceiling priority) in order to make the mapping between deadlines and priorities work. Thus, we require both policies to be specified if EDF is used in the partition.

Dynamic Semantics

12/3 {AI95-00357-01} {AI05-0229-1} The `Relative_Deadline` aspect has no effect if it is specified for a subprogram other than the main subprogram.

13/3 {AI95-00357-01} {AI05-0229-1} The initial absolute deadline of a task for which aspect `Relative_Deadline` is specified is the value of `Real_Time.Clock` + the expression that is the value of the aspect, where this entire expression, including the call of `Real_Time.Clock`, is evaluated between task creation and the start of its activation. If the aspect `Relative_Deadline` is not specified, then the initial absolute deadline of a task is the value of `Default_Deadline`. The environment task is also given an initial deadline by this rule, using the value of the `Relative_Deadline` aspect of the main subprogram (if any).

13.a/2 **Proof:** The environment task is a normal task by 10.2, so of course this rule applies to it.

14/2 {AI95-00357-01} The procedure `Set_Deadline` changes the absolute deadline of the task to `D`. The function `Get_Deadline` returns the absolute deadline of the task.

15/2 {AI95-00357-01} The procedure `Delay_Until_And_Set_Deadline` delays the calling task until time `Delay_Until_Time`. When the task becomes runnable again it will have deadline `Delay_Until_Time + Deadline_Offset`.

16/2 {AI95-00357-01} On a system with a single processor, the setting of the deadline of a task to the new value occurs immediately at the first point that is outside the execution of a protected action. If the task is currently on a ready queue it is removed and re-entered on to the ready queue determined by the rules defined below.

17/2 {AI95-00357-01} When `EDF_Across_Priorities` is specified for priority range *Low..High* all ready queues in this range are ordered by deadline. The task at the head of a queue is the one with the earliest deadline.

18/2 {AI95-00357-01} A task dispatching point occurs for the currently running task *T* to which policy `EDF_Across_Priorities` applies:

- 19/2 • when a change to the deadline of *T* occurs;
- 20/2 • there is a task on the ready queue for the active priority of *T* with a deadline earlier than the deadline of *T*; or

- there is a nonempty ready queue for that processor with a higher priority than the active priority of the running task. 21/2

In these cases, the currently running task is said to be preempted and is returned to the ready queue for its active priority. 22/2

{AI95-00357-01} For a task *T* to which policy EDF_Across_Priorities applies, the base priority is not a source of priority inheritance; the active priority when first activated or while it is blocked is defined as the maximum of the following: 23/2

- the lowest priority in the range specified as EDF_Across_Priorities that includes the base priority of *T*; 24/2
- the priorities, if any, currently inherited by *T*; 25/2
- {AI05-0055-1} the highest priority *P*, if any, less than the base priority of *T* such that one or more tasks are executing within a protected object with ceiling priority *P* and task *T* has an earlier deadline than all such tasks; and furthermore *T* has an earlier deadline than all other tasks on ready queues with priorities in the given EDF_Across_Priorities range that are strictly less than *P*. 26/3

Ramification: The active priority of *T* might be lower than its base priority. 26.a/2

{AI95-00357-01} When a task *T* is first activated or becomes unblocked, it is added to the ready queue corresponding to this active priority. Until it becomes blocked again, the active priority of *T* remains no less than this value; it will exceed this value only while it is inheriting a higher priority. 27/2

Discussion: These rules ensure that a task executing in a protected object is preempted only by a task with a shorter deadline and a higher base priority. This matches the traditional preemption level description without the need to define a new kind of protected object locking. 27.a/2

{AI95-00357-01} When the setting of the base priority of a ready task takes effect and the new priority is in a range specified as EDF_Across_Priorities, the task is added to the ready queue corresponding to its new active priority, as determined above. 28/2

{AI95-00357-01} For all the operations defined in Dispatching.EDF, Tasking_Error is raised if the task identified by *T* has terminated. Program_Error is raised if the value of *T* is Null_Task_Id. 29/2

Bounded (Run-Time) Errors

{AI95-00357-01} If EDF_Across_Priorities is specified for priority range *Low..High*, it is a bounded error to declare a protected object with ceiling priority *Low* or to assign the value *Low* to attribute 'Priority. In either case either Program_Error is raised or the ceiling of the protected object is assigned the value *Low*+1. 30/2

Erroneous Execution

{AI95-00357-01} If a value of Task_Id is passed as a parameter to any of the subprograms of this package and the corresponding task object no longer exists, the execution of the program is erroneous. 31/2

Documentation Requirements

{AI95-00357-01} On a multiprocessor, the implementation shall document any conditions that cause the completion of the setting of the deadline of a task to be delayed later than what is specified for a single processor. 32/2

Documentation Requirement: Any conditions that cause the completion of the setting of the deadline of a task to be delayed for a multiprocessor. 32.a.1/2

NOTES

18 {AI95-00357-01} {AI05-0264-1} If two adjacent priority ranges, *A..B* and *B+1..C* are specified to have policy EDF_Across_Priorities, then this is not equivalent to this policy being specified for the single range, *A..C*. 33/3

34/2 19 {AI95-00357-01} The above rules implement the preemption-level protocol (also called Stack Resource Policy protocol) for resource sharing under EDF dispatching. The preemption-level for a task is denoted by its base priority. The definition of a ceiling preemption-level for a protected object follows the existing rules for ceiling locking.

34.a/2 **Implementation Note:** {AI95-00357-01} An implementation may support additional dispatching policies by replacing absolute deadline with an alternative measure of urgency.

Extensions to Ada 95

34.b/2 {AI95-00357-01} Policy EDF_Across_Priorities and package Dispatching.EDF are new.

Extensions to Ada 2005

34.c/3 {AI05-0229-1} Aspect Relative_Deadline is new; pragma Relative_Deadline is now obsolescent.

Wording Changes from Ada 2005

34.d/3 {AI05-0055-1} **Correction:** Corrected definition of active priority to avoid deadline inversion in an unusual case.

D.3 Priority Ceiling Locking

1/3 {AI05-0299-1} [This subclause specifies the interactions between priority task scheduling and protected object ceilings. This interaction is based on the concept of the *ceiling priority* of a protected object.]

Syntax

2 The form of a pragma Locking_Policy is as follows:

3 **pragma** Locking_Policy(*policy_identifier*);

Legality Rules

4 The *policy_identifier* shall either be Ceiling_Locking or an implementation-defined identifier.

4.a **Implementation defined:** Implementation-defined *policy_identifiers* allowed in a pragma Locking_Policy.

Post-Compilation Rules

5 A Locking_Policy pragma is a configuration pragma.

Dynamic Semantics

6/2 {8652/0073} {AI95-00091-01} {AI95-00327-01} [A locking policy specifies the details of protected object locking. All protected objects have a priority. The locking policy specifies the meaning of the priority of a protected object, and the relationships between these priorities and task priorities. In addition, the policy specifies the state of a task when it executes a protected action, and how its active priority is affected by the locking.] The *locking policy* is specified by a Locking_Policy pragma. For implementation-defined locking policies, the meaning of the priority of a protected object is implementation defined. If no Locking_Policy pragma applies to any of the program units comprising a partition, the locking policy for that partition, as well as the meaning of the priority of a protected object, are implementation defined.

6.a/2 **Implementation defined:** The locking policy if no Locking_Policy pragma applies to any unit of a partition.

6.1/3 {AI95-00327-01} {AI05-0229-1} The expression specified for the Priority or Interrupt_Priority aspect (see D.1) is evaluated as part of the creation of the corresponding protected object and converted to the subtype System.Any_Priority or System.Interrupt_Priority, respectively. The value of the expression is the initial priority of the corresponding protected object. If no Priority or Interrupt_Priority aspect is specified for a protected object, the initial priority is specified by the locking policy.

7 There is one predefined locking policy, Ceiling_Locking; this policy is defined as follows:

- {AI95-00327-01} {AI05-0229-1} Every protected object has a *ceiling priority*, which is determined by either a Priority or Interrupt_Priority aspect as defined in D.1, or by assignment to the Priority attribute as described in D.5.2. The ceiling priority of a protected object (or ceiling, for short) is an upper bound on the active priority a task can have when it calls protected operations of that protected object. 8/3
- {AI95-00327-01} The initial ceiling priority of a protected object is equal to the initial priority for that object. 9/2
- {AI95-00327-01} {AI05-0229-1} If an Interrupt_Handler or Attach_Handler aspect (see C.3.1) is specified for a protected subprogram of a protected type that does not have the Interrupt_Priority aspect specified, the initial priority of protected objects of that type is implementation defined, but in the range of the subtype System.Interrupt_Priority. 10/3

Implementation defined: Default ceiling priorities.

- {AI95-00327-01} {AI05-0229-1} If neither aspect Priority nor Interrupt_Priority is specified for a protected type, and no protected subprogram of the type has aspect Interrupt_Handler or Attach_Handler specified, then the initial priority of the corresponding protected object is System.Priority'Last. 10.a 11/3
- While a task executes a protected action, it inherits the ceiling priority of the corresponding protected object. 12
- When a task calls a protected operation, a check is made that its active priority is not higher than the ceiling of the corresponding protected object; Program_Error is raised if this check fails. 13

Bounded (Run-Time) Errors

{AI95-00327-01} Following any change of priority, it is a bounded error for the active priority of any task with a call queued on an entry of a protected object to be higher than the ceiling priority of the protected object. In this case one of the following applies: 13.1/2

- at any time prior to executing the entry body Program_Error is raised in the calling task; 13.2/2
- when the entry is open the entry body is executed at the ceiling priority of the protected object; 13.3/2
- when the entry is open the entry body is executed at the ceiling priority of the protected object and then Program_Error is raised in the calling task; or 13.4/2
- when the entry is open the entry body is executed at the ceiling priority of the protected object that was in effect when the entry call was queued. 13.5/2

Ramification: Note that the error is “blamed” on the task that did the entry call, not the task that changed the priority of the task or protected object. This seems to make sense for the case of changing the priority of a task blocked on a call, since if the Set_Priority had happened a little bit sooner, before the task queued a call, the entry-calling task would get the error. Similarly, there is no reason not to raise the priority of a task that is executing in an abortable_part, so long as its priority is lowered before it gets to the end and needs to cancel the call. The priority might need to be lowered to allow it to remove the call from the entry queue, in order to avoid violating the ceiling. This seems relatively harmless, since there is an error, and the task is about to start raising an exception anyway. 13.a.1/2

Implementation Permissions

The implementation is allowed to round all ceilings in a certain subrange of System.Priority or System.Interrupt_Priority up to the top of that subrange, uniformly. 14

Discussion: For example, an implementation might use Priority'Last for all ceilings in Priority, and Interrupt_Priority'Last for all ceilings in Interrupt_Priority. This would be equivalent to having two ceiling priorities for protected objects, “nonpreemptible” and “noninterruptible”, and is an allowed behavior. 14.a

Note that the implementation cannot choose a subrange that crosses the boundary between normal and interrupt priorities. 14.b

{AI95-00256-01} Implementations are allowed to define other locking policies, but need not support more than one locking policy per partition. 15/2

16 [Since implementations are allowed to place restrictions on code that runs at an interrupt-level active priority (see C.3.1 and D.2.1), the implementation may implement a language feature in terms of a protected object with an implementation-defined ceiling, but the ceiling shall be no less than Priority'Last.]

16.a **Implementation defined:** The ceiling of any protected object used internally by the implementation.

16.b **Proof:** This permission follows from the fact that the implementation can place restrictions on interrupt handlers and on any other code that runs at an interrupt-level active priority.

16.c The implementation might protect a storage pool with a protected object whose ceiling is Priority'Last, which would cause allocators to fail when evaluated at interrupt priority. Note that the ceiling of such an object has to be at least Priority'Last, since there is no permission for allocators to fail when evaluated at a noninterrupt priority.

Implementation Advice

17 The implementation should use names that end with “_Locking” for implementation-defined locking policies.

17.a/2 **Implementation Advice:** Names that end with “_Locking” should be used for implementation-defined locking policies.

NOTES

18 20 While a task executes in a protected action, it can be preempted only by tasks whose active priorities are higher than the ceiling priority of the protected object.

19 21 If a protected object has a ceiling priority in the range of Interrupt_Priority, certain interrupts are blocked while protected actions of that object execute. In the extreme, if the ceiling is Interrupt_Priority'Last, all blockable interrupts are blocked during that time.

20 22 The ceiling priority of a protected object has to be in the Interrupt_Priority range if one of its procedures is to be used as an interrupt handler (see C.3).

21 23 When specifying the ceiling of a protected object, one should choose a value that is at least as high as the highest active priority at which tasks can be executing when they call protected operations of that object. In determining this value the following factors, which can affect active priority, should be considered: the effect of Set_Priority, nested protected operations, entry calls, task activation, and other implementation-defined factors.

22 24 Attaching a protected procedure whose ceiling is below the interrupt hardware priority to an interrupt causes the execution of the program to be erroneous (see C.3.1).

23 25 On a single processor implementation, the ceiling priority rules guarantee that there is no possibility of deadlock involving only protected subprograms (excluding the case where a protected operation calls another protected operation on the same protected object).

Extensions to Ada 95

23.a/2 {AI95-00327-01} All protected objects now have a priority, which is the value of the Priority attribute of D.5.2. How this value is interpreted depends on the locking policy; for instance, the ceiling priority is derived from this value when the locking policy is Ceiling_Locking.

Wording Changes from Ada 95

23.b/2 {8652/0073} {AI95-00091-01} **Corrigendum:** Corrected the wording to reflect that pragma Locking_Policy cannot be inside of a program unit.

23.c/2 {AI95-00256-01} Clarified that an implementation need support only one locking policy (of any kind, language-defined or otherwise) per partition.

23.d/2 {AI95-00327-01} The bounded error for the priority of a task being higher than the ceiling of an object it is currently in was moved here from D.5, so that it applies no matter how the situation arises.

Wording Changes from Ada 2005

23.e/3 {AI05-0229-1} Revised to use aspects Priority and Interrupt_Priority as pragmas Priority and Interrupt_Priority are now obsolescent.

D.4 Entry Queuing Policies

{8652/0074} {AI95-00068-01} {AI05-0299-1} [This subclause specifies a mechanism for a user to choose an entry *queuing policy*. It also defines two such policies. Other policies are implementation defined.] 1/3

Implementation defined: Implementation-defined queuing policies. 1.a

Syntax

The form of a pragma `Queuing_Policy` is as follows: 2

pragma `Queuing_Policy`(*policy_identifier*); 3

Legality Rules

The *policy_identifier* shall be either `FIFO_Queueing`, `Priority_Queueing` or an implementation-defined identifier. 4

Post-Compilation Rules

A `Queuing_Policy` pragma is a configuration pragma. 5

Dynamic Semantics

[A *queuing policy* governs the order in which tasks are queued for entry service, and the order in which different entry queues are considered for service.] The queuing policy is specified by a `Queuing_Policy` pragma. 6

Ramification: The queuing policy includes entry queuing order, the choice among open alternatives of a `selective_accept`, and the choice among queued entry calls of a protected object when more than one `entry_barrier` condition is True. 6.a

{AI95-00355-01} Two queuing policies, `FIFO_Queueing` and `Priority_Queueing`, are language defined. If no `Queuing_Policy` pragma applies to any of the program units comprising the partition, the queuing policy for that partition is `FIFO_Queueing`. The rules for this policy are specified in 9.5.3 and 9.7.1. 7/2

The `Priority_Queueing` policy is defined as follows: 8

- The calls to an entry [(including a member of an entry family)] are queued in an order consistent with the priorities of the calls. The *priority of an entry call* is initialized from the active priority of the calling task at the time the call is made, but can change later. Within the same priority, the order is consistent with the calling (or requeuing, or priority setting) time (that is, a FIFO order). 9
- {8652/0075} {AI95-00205-01} After a call is first queued, changes to the active priority of a task do not affect the priority of the call, unless the base priority of the task is set while the task is blocked on an entry call. 10/1
- When the base priority of a task is set (see D.5), if the task is blocked on an entry call, and the call is queued, the priority of the call is updated to the new active priority of the calling task. This causes the call to be removed from and then reinserted in the queue at the new active priority. 11

Reason: A task is blocked on an entry call if the entry call is simple, conditional, or timed. If the call came from the `triggering_statement` of an `asynchronous_select`, or a requeue thereof, then the task is not blocked on that call; such calls do not have their priority updated. Thus, there can exist many queued calls from a given task (caused by many nested ATC's), but a task can be blocked on only one call at a time. 11.a

A previous version of Ada 9X required queue reordering in the `asynchronous_select` case as well. If the call corresponds to a “synchronous” entry call, then the task is blocked while queued, and it makes good sense to move it up in the queue if its priority is raised. 11.b

- 11.c However, if the entry call is “asynchronous,” that is, it is due to an `asynchronous_select` whose `triggering_statement` is an entry call, then the task is not waiting for this entry call, so the placement of the entry call on the queue is irrelevant to the rate at which the task proceeds.
- 11.d Furthermore, when an entry is used for `asynchronous_selects`, it is almost certain to be a “broadcast” entry or have only one caller at a time. For example, if the entry is used to notify tasks of a mode switch, then all tasks on the entry queue would be signaled when the mode changes. Similarly, if it is indicating some interrupting event such as a control-C, all tasks sensitive to the interrupt will want to be informed that the event occurred. Hence, the order on such a queue is essentially irrelevant.
- 11.e Given the above, it seems an unnecessary semantic and implementation complexity to specify that asynchronous queued calls are moved in response to dynamic priority changes. Furthermore, it is somewhat inconsistent, since the call was originally queued based on the active priority of the task, but dynamic priority changes are changing the base priority of the task, and only indirectly the active priority. We say explicitly that asynchronous queued calls are not affected by normal changes in active priority during the execution of an `abortable_part`. Saying that, if a change in the base priority affects the active priority, then we do want the calls reordered, would be inconsistent. It would also require the implementation to maintain a readily accessible list of all queued calls which would not otherwise be necessary.
- 11.f Several rules were removed or simplified when we changed the rules so that calls due to `asynchronous_selects` are never moved due to intervening changes in active priority, be they due to protected actions, some other priority inheritance, or changes in the base priority.
- 12 • When more than one condition of an `entry_barrier` of a protected object becomes True, and more than one of the respective queues is nonempty, the call with the highest priority is selected. If more than one such call has the same priority, the call that is queued on the entry whose declaration is first in textual order in the `protected_definition` is selected. For members of the same entry family, the one with the lower family index is selected.
- 13 • If the expiration time of two or more open `delay_alternatives` is the same and no other `accept_alternatives` are open, the `sequence_of_statements` of the `delay_alternative` that is first in textual order in the `selective_accept` is executed.
- 14 • When more than one alternative of a `selective_accept` is open and has queued calls, an alternative whose queue has the highest-priority call at its head is selected. If two or more open alternatives have equal-priority queued calls, then a call on the entry in the `accept_alternative` that is first in textual order in the `selective_accept` is selected.

Implementation Permissions

- 15/2 {*AI95-00256-01*} Implementations are allowed to define other queuing policies, but need not support more than one queuing policy per partition.
- 15.a.1/2 **Discussion:** {*8652/0116*} {*AI95-00069-01*} {*AI95-00256-01*} This rule is really redundant, as 10.1.5 allows an implementation to limit the use of configuration pragmas to an empty environment. In that case, there would be no way to have multiple policies in a partition.
- 15.1/2 {*AI95-00188-02*} Implementations are allowed to defer the reordering of entry queues following a change of base priority of a task blocked on the entry call if it is not practical to reorder the queue immediately.
- 15.a.2/2 **Reason:** Priority change is immediate, but the effect of the change on entry queues can be deferred. That is necessary in order to implement priority changes on top of a non-Ada kernel.
- 15.a.3/2 **Discussion:** The reordering should occur as soon as the blocked task can itself perform the reinsertion into the entry queue.

Implementation Advice

- 16 The implementation should use names that end with “_Queuing” for implementation-defined queuing policies.
- 16.a/2 **Implementation Advice:** Names that end with “_Queuing” should be used for implementation-defined queuing policies.

Wording Changes from Ada 95

- 16.b/2 {*8652/0074*} {*AI95-00068-01*} **Corrigendum:** Corrected the number of queuing policies defined.

- {8652/0075} {AI95-00205-01} **Corrigendum:** Corrected so that a call of Set_Priority in an abortable part does not change the priority of the triggering entry call. 16.c/2
- {AI95-00188-02} Added a permission to defer queue reordering when the base priority of a task is changed. This is a counterpart to stronger requirements on the implementation of priority change. 16.d/2
- {AI95-00256-01} Clarified that an implementation need support only one queuing policy (of any kind, language-defined or otherwise) per partition. 16.e/2
- {AI95-00355-01} Fixed wording to make clear that pragma never appears inside of a unit; rather it “applies to” the unit. 16.f/2

D.5 Dynamic Priorities

- {AI95-00327-01} {AI05-0299-1} [This subclause describes how the priority of an entity can be modified or queried at run time.] 1/3

Wording Changes from Ada 95

- {AI95-00327-01} {AI05-0299-1} This subclause is turned into two subclauses. This subclause introduction is new. 1.a/3

D.5.1 Dynamic Priorities for Tasks

- {AI05-0299-1} [This subclause describes how the base priority of a task can be modified or queried at run time.] 1/3

Static Semantics

The following language-defined library package exists: 2

```
{AI95-00362-01} with System;
with Ada.Task_Identification; -- See C.7.1
package Ada.Dynamic_Priorities is
  pragma Preelaborate(Dynamic_Priorities);
  procedure Set_Priority(Priority : in System.Any_Priority;
                       T : in Ada.Task_Identification.Task_Id :=
                          Ada.Task_Identification.Current_Task);
  function Get_Priority(T : Ada.Task_Identification.Task_Id :=
                       Ada.Task_Identification.Current_Task)
    return System.Any_Priority;
end Ada.Dynamic_Priorities;
```

3/2
4
5
6

Dynamic Semantics

The procedure Set_Priority sets the base priority of the specified task to the specified Priority value. Set_Priority has no effect if the task is terminated. 7

The function Get_Priority returns T's current base priority. Tasking_Error is raised if the task is terminated. 8

Reason: There is no harm in setting the priority of a terminated task. A previous version of Ada 9X made this a run-time error. However, there is little difference between setting the priority of a terminated task, and setting the priority of a task that is about to terminate very soon; neither case should be an error. Furthermore, the run-time check is not necessarily feasible to implement on all systems, since priority changes might be deferred due to inter-processor communication overhead, so the error might not be detected until after Set_Priority has returned. 8.a

However, we wish to allow implementations to avoid storing “extra” information about terminated tasks. Therefore, we make Get_Priority of a terminated task raise an exception; the implementation need not continue to store the priority of a task that has terminated. 8.b

Program_Error is raised by Set_Priority and Get_Priority if T is equal to Null_Task_Id. 9

- {AI95-00188-02} On a system with a single processor, the setting of the base priority of a task T to the new value occurs immediately at the first point when T is outside the execution of a protected action. 10/2

- 10.a/2 **Implementation Note:** *{AI95-00188-02}* The priority change is immediate if the target task is on a delay queue or a ready queue outside of a protected action. However, consider when `Set_Priority` is called by a task T1 to set the priority of T2, if T2 is blocked, waiting on an entry call queued on a protected object, the entry queue needs to be reordered. Since T1 might have a priority that is higher than the ceiling of the protected object, T1 cannot, in general, do the reordering. One way to implement this is to wake T2 up and have T2 do the work. This is similar to the disentangling of queues that needs to happen when a high-priority task aborts a lower-priority task, which might have a call queued on a protected object with a low ceiling. We have an Implementation Permission in D.4 to allow this implementation. We could have required an immediate priority change if on a ready queue during a protected action, but that would have required extra checks for ceiling violations to meet Bounded (Run-Time) Error requirements of D.3 and potentially could cause a protected action to be abandoned in the middle (by raising `Program_Error`). That seems bad.
- 10.b **Reason:** A previous version of Ada 9X made it a run-time error for a high-priority task to set the priority of a lower-priority task that has a queued call on a protected object with a low ceiling. This was changed because:
- 10.c
- The check was not feasible to implement on all systems, since priority changes might be deferred due to inter-processor communication overhead. The calling task would continue to execute without finding out whether the operation succeeded or not.
- 10.d
- The run-time check would tend to cause intermittent system failures — how is the caller supposed to know whether the other task happens to have a queued call at any given time? Consider for example an interrupt that needs to trigger a priority change in some task. The interrupt handler could not safely call `Set_Priority` without knowing exactly what the other task is doing, or without severely restricting the ceilings used in the system. If the interrupt handler wants to hand the job off to a third task whose job is to call `Set_Priority`, this won't help, because one would normally want the third task to have high priority.

Paragraph 11 was deleted.

Erroneous Execution

- 12 If any subprogram in this package is called with a parameter T that specifies a task object that no longer exists, the execution of the program is erroneous.
- 12.a **Ramification:** Note that this rule overrides the above rule saying that `Program_Error` is raised on `Get_Priority` of a terminated task. If the task object still exists, and the task is terminated, `Get_Priority` raises `Program_Error`. However, if the task object no longer exists, calling `Get_Priority` causes erroneous execution.

Documentation Requirements

- 12.1/2 *{AI95-00188-02}* On a multiprocessor, the implementation shall document any conditions that cause the completion of the setting of the priority of a task to be delayed later than what is specified for a single processor.
- 12.a.1/2 **Documentation Requirement:** Any conditions that cause the completion of the setting of the priority of a task to be delayed for a multiprocessor.

Metrics

- 13 The implementation shall document the following metric:
- 14
- The execution time of a call to `Set_Priority`, for the nonpreempting case, in processor clock cycles. This is measured for a call that modifies the priority of a ready task that is not running (which cannot be the calling one), where the new base priority of the affected task is lower than the active priority of the calling task, and the affected task is not on any entry queue and is not executing a protected operation.

- 14.a/2 **Documentation Requirement:** The metrics for `Set_Priority`.

NOTES

- 15/2 26 *{AI95-00321-01}* Setting a task's base priority affects task dispatching. First, it can change the task's active priority. Second, under the `FIFO_Within_Priorities` policy it always causes the task to move to the tail of the ready queue corresponding to its active priority, even if the new base priority is unchanged.
- 16 27 Under the priority queuing policy, setting a task's base priority has an effect on a queued entry call if the task is blocked waiting for the call. That is, setting the base priority of a task causes the priority of a queued entry call from that task to be updated and the call to be removed and then reinserted in the entry queue at the new priority (see D.4), unless the call originated from the `triggering_statement` of an `asynchronous_select`.

- 28 The effect of two or more `Set_Priority` calls executed in parallel on the same task is defined as executing these calls in some serial order. 17
- Proof:** This follows from the general reentrancy requirements stated near the beginning of Annex A, “Predefined Language Environment”. 17.a
- 29 {*AI05-0092-1*} The rule for when `Tasking_Error` is raised for `Set_Priority` or `Get_Priority` is different from the rule for when `Tasking_Error` is raised on an entry call (see 9.5.3). In particular, querying the priority of a completed or an abnormal task is allowed, so long as the task is not yet terminated, and setting the priority of a task is allowed for any task state (including for terminated tasks). 18/3
- 30 Changing the priorities of a set of tasks can be performed by a series of calls to `Set_Priority` for each task separately. For this to work reliably, it should be done within a protected operation that has high enough ceiling priority to guarantee that the operation completes without being preempted by any of the affected tasks. 19

Extensions to Ada 95

{*AI95-00188-02*} **Amendment Correction:** Priority changes are now required to be done immediately so long as the target task is not on an entry queue. 19.a/2

{*AI95-00362-01*} `Dynamic_Priorities` is now Preelaborated, so it can be used in preelaborated units. 19.b/2

Wording Changes from Ada 95

{*AI95-00327-01*} {*AI05-0299-1*} This Ada 95 subclause was moved down a level. The paragraph numbers are the same as those for D.5 in Ada 95. 19.c/3

{*AI95-00321-01*} There is no “standard” policy anymore, so that phrase was replaced by the name of a specific policy in the notes. 19.d/2

{*AI95-00327-01*} The bounded error for the priority of a task being higher than the ceiling of an object it is currently in was moved to D.3, so that it applies no matter how the situation arises. 19.e/2

D.5.2 Dynamic Priorities for Protected Objects

{*AI95-00327-01*} {*AI05-0299-1*} This subclause specifies how the priority of a protected object can be modified or queried at run time. 1/3

Static Semantics

{*AI95-00327-01*} The following attribute is defined for a prefix `P` that denotes a protected object: 2/2

`P'Priority` {*AI95-00327-01*} Denotes a non-aliased component of the protected object `P`. This component is of type `System.Any_Priority` and its value is the priority of `P`. `P'Priority` denotes a variable if and only if `P` denotes a variable. A reference to this attribute shall appear only within the body of `P`. 3/2

{*AI95-00327-01*} The initial value of this attribute is the initial value of the priority of the protected object[, and can be changed by an assignment]. 4/2

Dynamic Semantics

{*AI95-00327-01*} {*AI05-0264-1*} If the locking policy `Ceiling_Locking` (see D.3) is in effect, then the ceiling priority of a protected object `P` is set to the value of `P'Priority` at the end of each protected action of `P`. 5/3

{*AI95-00445-01*} {*AI05-0229-1*} If the locking policy `Ceiling_Locking` is in effect, then for a protected object `P` with either an `Attach_Handler` or `Interrupt_Handler` aspect specified for one of its procedures, a check is made that the value to be assigned to `P'Priority` is in the range `System.Interrupt_Priority`. If the check fails, `Program_Error` is raised. 6/3

Metrics

{*AI95-00327-01*} The implementation shall document the following metric: 7/2

- The difference in execution time of calls to the following procedures in protected object `P`: 8/2

```

9/2   protected P is
      procedure Do_Not_Set_Ceiling (Pr : System.Any_Priority);
      procedure Set_Ceiling (Pr : System.Any_Priority);
    end P;

10/2  protected body P is
      procedure Do_Not_Set_Ceiling (Pr : System.Any_Priority) is
      begin
          null;
      end;
      procedure Set_Ceiling (Pr : System.Any_Priority) is
      begin
          P'Priority := Pr;
      end;
    end P;

```

10.a/2 **Documentation Requirement:** The metrics for setting the priority of a protected object.

NOTES

11/2 31 {AI95-00327-01} Since P'Priority is a normal variable, the value following an assignment to the attribute immediately reflects the new value even though its impact on the ceiling priority of P is postponed until completion of the protected action in which it is executed.

Extensions to Ada 95

11.a/2 {AI95-00327-01} {AI95-00445-01} The ability to dynamically change and query the priority of a protected object is new.

D.6 Preemptive Abort

1/3 {AI05-0299-1} [This subclause specifies requirements on the immediacy with which an aborted construct is completed.]

Dynamic Semantics

2 On a system with a single processor, an aborted construct is completed immediately at the first point that is outside the execution of an abort-deferred operation.

Documentation Requirements

3 On a multiprocessor, the implementation shall document any conditions that cause the completion of an aborted construct to be delayed later than what is specified for a single processor.

3.a/2 *This paragraph was deleted.*

3.b/2 **Documentation Requirement:** On a multiprocessor, any conditions that cause the completion of an aborted construct to be delayed later than what is specified for a single processor.

Metrics

4 The implementation shall document the following metrics:

- 5 • The execution time, in processor clock cycles, that it takes for an `abort_statement` to cause the completion of the aborted task. This is measured in a situation where a task T2 preempts task T1 and aborts T1. T1 does not have any finalization code. T2 shall verify that T1 has terminated, by means of the Terminated attribute.
- 6 • On a multiprocessor, an upper bound in seconds, on the time that the completion of an aborted task can be delayed beyond the point that it is required for a single processor.
- 7/2 • {AI95-00114-01} An upper bound on the execution time of an `asynchronous_select`, in processor clock cycles. This is measured between a point immediately before a task T1 executes a protected operation Pr.Set that makes the condition of an `entry_barrier Pr.Wait True`, and the point where task T2 resumes execution immediately after an entry call to Pr.Wait in an

`asynchronous_select`. T1 preempts T2 while T2 is executing the abortable part, and then blocks itself so that T2 can execute. The execution time of T1 is measured separately, and subtracted.

- An upper bound on the execution time of an `asynchronous_select`, in the case that no asynchronous transfer of control takes place. This is measured between a point immediately before a task executes the `asynchronous_select` with a nonnull abortable part, and the point where the task continues execution immediately after it. The execution time of the abortable part is subtracted. 8

Documentation Requirement: The metrics for aborts. 8.a/2

Implementation Advice

Even though the `abort_statement` is included in the list of potentially blocking operations (see 9.5.1), it is recommended that this statement be implemented in a way that never requires the task executing the `abort_statement` to block. 9

Implementation Advice: The `abort_statement` should not require the task executing the statement to block. 9.a/2

On a multi-processor, the delay associated with aborting a task on another processor should be bounded; the implementation should use periodic polling, if necessary, to achieve this. 10

Implementation Advice: On a multi-processor, the delay associated with aborting a task on another processor should be bounded. 10.a/2

NOTES

32 Abortion does not change the active or base priority of the aborted task. 11

33 Abortion cannot be more immediate than is allowed by the rules for deferral of abortion during finalization and in protected actions. 12

D.7 Tasking Restrictions

{AI05-0299-1} [This subclause defines restrictions that can be used with a pragma Restrictions (see 13.12) to facilitate the construction of highly efficient tasking run-time systems.] 1/3

Static Semantics

The following *restriction_identifiers* are language defined: 2

{AI05-0013-1} {AI05-0216-1} No_Task_Hierarchy 3/3

No task depends on a master other than the library-level master.

Ramification: {AI05-0216-1} This is equivalent to saying “no task depends on a master other than the master that is the execution of the body of the environment task of the partition”, but it is much easier to understand. This is a post-compilation check, which can be checked at compile-time. 3.a/3

{AI05-0013-1} This disallows any function returning an object with a task part or coextension, even if called at the library level, as such a task would temporarily depend on a nested master (the master of the return statement), which is disallowed by this restriction. 3.b/3

{8652/0042} {AI95-00130-01} {AI95-00360-01} {AI05-0013-1} No_Nested_Finalization 4/3

Objects of a type that needs finalization (see 7.6) are declared only at library level. If an access type does not have library-level accessibility, then there are no allocators of the type where the type determined by the `subtype_mark` of the `subtype_indication` or `qualified_expression` needs finalization.

This paragraph was deleted. {8652/0042} {AI95-00130-01} 4.a/1

Ramification: {AI05-0013-1} The second sentence prevents the declaration of objects of access types which would require nested finalization. It also prevents the declarations of coextensions that need finalization in a nested scope. The latter cannot be done by preventing the declaration of the objects, as it is not necessarily known if the coextension type needs finalization (it could be a limited view). 4.b/3

- 5/3 {AI05-0211-1} No_Abort_Statements
 There are no `abort_statements`, and there is no use of a name denoting `Task_Identification.Abort_Task`.
- 6 No_Terminate_Alternatives
 There are no `selective_accepts` with `terminate_alternatives`.
- 7 No_Task_Allocators
 There are no `allocators` for task types or types containing task subcomponents.
- 7.1/3 {AI05-0224-1} In the case of an initialized `allocator` of an access type whose designated type is class-wide and limited, a check is made that the specific type of the allocated object has no task subcomponents. `Program_Error` is raised if this check fails.
- 8 No_Implicit_Heap_Allocations
 There are no operations that implicitly require heap storage allocation to be performed by the implementation. The operations that implicitly require heap storage allocation are implementation defined.
- 8.a **Implementation defined:** Any operations that implicitly require heap storage allocation.
- 9/2 {AI95-00327-01} No_Dynamic_Priorities
 There are no semantic dependences on the package `Dynamic_Priorities`, and no occurrences of the attribute `Priority`.
- 10/3 {AI95-00305-01} {AI95-00394-01} {AI05-0013-1} {AI05-0211-1} No_Dynamic_Attachment
 There is no use of a name denoting any of the operations defined in package `Interrupts` (`Is_Reserved`, `Is_Attached`, `Current_Handler`, `Attach_Handler`, `Exchange_Handler`, `Detach_Handler`, and `Reference`).
- 10.a/3 **Ramification:** {AI05-0013-1} This includes 'Access and 'Address of any of these operations, as well as inherited versions of these operations.
- 10.1/3 {AI95-00305-01} {AI05-0013-1} No_Local_Protected_Objects
 Protected objects are declared only at library level.
- 10.2/3 {AI95-00297-01} {AI05-0013-1} No_Local_Timing_Events
`Timing_Events` are declared only at library level.
- 10.3/2 {AI95-00305-01} No_Protected_Type_Allocators
 There are no `allocators` for protected types or types containing protected type subcomponents.
- 10.4/3 {AI05-0224-1} In the case of an initialized `allocator` of an access type whose designated type is class-wide and limited, a check is made that the specific type of the allocated object has no protected subcomponents. `Program_Error` is raised if this check fails.
- 10.5/3 {AI95-00305-01} {AI05-0211-1} No_Relative_Delay
 There are no `delay_relative_statements`, and there is no use of a name that denotes the `Timing_Events.Set_Handler` subprogram that has a `Time_Span` parameter.
- 10.6/3 {AI95-00305-01} No_Requeue_Statements
 There are no `requeue_statements`.
- 10.7/3 {AI95-00305-01} No_Select_Statements
 There are no `select_statements`.
- 10.8/3 {AI95-00394-01} {AI05-0211-1} No_Specific_Termination_Handlers
 There is no use of a name denoting the `Set_Specific_Handler` and `Specific_Handler` subprograms in `Task_Termination`.

<code>{AI95-00305-01}</code> <code>{AI05-0013-1}</code> <code>Simple_Barriers</code>	10.9/3
The Boolean expression in each entry barrier is either a static expression or a name that statically denotes a component of the enclosing protected object.	
The following <i>restriction_parameter_identifiers</i> are language defined:	11
<code>Max_Select_Alternatives</code>	12
Specifies the maximum number of alternatives in a <code>selective_accept</code> .	
<code>Max_Task_Entries</code>	13
Specifies the maximum number of entries per task. The bounds of every entry family of a task unit shall be static, or shall be defined by a discriminant of a subtype whose corresponding bound is static. [A value of zero indicates that no rendezvous are possible.]	
<code>Max_Protected_Entries</code>	14
Specifies the maximum number of entries per protected type. The bounds of every entry family of a protected unit shall be static, or shall be defined by a discriminant of a subtype whose corresponding bound is static.	
<i>Dynamic Semantics</i>	
<code>{8652/0076}</code> <code>{AI95-00067-01}</code> <code>{AI95-00305-01}</code> The following <i>restriction_identifier</i> is language defined:	15/2
<code>{AI95-00305-01}</code> <code>{AI95-00394-01}</code> <code>No_Task_Termination</code>	15.1/2
All tasks are nonterminating. It is implementation-defined what happens if a task attempts to terminate. If there is a fall-back handler (see C.7.3) set for the partition it should be called when the first task attempts to terminate.	
Implementation defined: When restriction <code>No_Task_Termination</code> applies to a partition, what happens when a task terminates.	15.a.1/2
The following <i>restriction_parameter_identifiers</i> are language defined:	16
<code>{8652/0076}</code> <code>{AI95-00067-01}</code> <code>Max_Storage_At_Blocking</code>	17/1
Specifies the maximum portion [(in storage elements)] of a task's <code>Storage_Size</code> that can be retained by a blocked task. If an implementation chooses to detect a violation of this restriction, <code>Storage_Error</code> should be raised; otherwise, the behavior is implementation defined.	
Implementation defined: The behavior when restriction <code>Max_Storage_At_Blocking</code> is violated.	17.a.1/2
<code>{8652/0076}</code> <code>{AI95-00067-01}</code> <code>Max_Asynchronous_Select_Nesting</code>	18/1
Specifies the maximum dynamic nesting level of <code>asynchronous_selects</code> . A value of zero prevents the use of any <code>asynchronous_select</code> and, if a program contains an <code>asynchronous_select</code> , it is illegal. If an implementation chooses to detect a violation of this restriction for values other than zero, <code>Storage_Error</code> should be raised; otherwise, the behavior is implementation defined.	
Implementation defined: The behavior when restriction <code>Max_Asynchronous_Select_Nesting</code> is violated.	18.a.1/2
<code>{8652/0076}</code> <code>{AI95-00067-01}</code> <code>Max_Tasks</code>	19/1
Specifies the maximum number of task creations that may be executed over the lifetime of a partition, not counting the creation of the environment task. A value of zero prevents any task creation and, if a program contains a task creation, it is illegal. If an implementation chooses to detect a violation of this restriction, <code>Storage_Error</code> should be raised; otherwise, the behavior is implementation defined.	
Ramification: Note that this is not a limit on the number of tasks active at a given time; it is a limit on the total number of task creations that occur.	19.a
Implementation Note: We envision an implementation approach that places TCBs or pointers to them in a fixed-size table, and never reuses table elements.	19.b

- 19.b.1/2 **Implementation defined:** The behavior when restriction `Max_Tasks` is violated.
- 19.1/2 `{AI95-00305-01}` `Max_Entry_Queue_Length`
 `Max_Entry_Queue_Length` defines the maximum number of calls that are queued on an entry. Violation of this restriction results in the raising of `Program_Error` at the point of the call or requeue.
- 19.2/3 `{AI05-0189-1}` `No_Standard_Allocators_After_Elaboration`
 Specifies that an allocator using a standard storage pool (see 13.11) shall not occur within a parameterless library subprogram, nor within the `handled_sequence_of_statements` of a task body. For the purposes of this rule, an allocator of a type derived from a formal access type does not use a standard storage pool.
- 19.3/3 `{AI05-0189-1}` `{AI05-0262-1}` At run time, `Storage_Error` is raised if an allocator using a standard storage pool is evaluated after the elaboration of the `library_items` of the partition has completed.
- 20 It is implementation defined whether the use of pragma Restrictions results in a reduction in executable program size, storage requirements, or execution time. If possible, the implementation should provide quantitative descriptions of such effects for each restriction.
- 20.a/2 **Implementation defined:** Whether the use of pragma Restrictions results in a reduction in program code or data size or execution time.

Implementation Advice

- 21 When feasible, the implementation should take advantage of the specified restrictions to produce a more efficient implementation.
- 21.a/2 **Implementation Advice:** When feasible, specified restrictions should be used to produce a more efficient implementation.
- NOTES
- 22 34 The above `Storage_Checks` can be suppressed with pragma Suppress.

Incompatibilities With Ada 95

- 22.a/2 `{AI95-00360-01}` **Amendment Correction:** The `No_Nested_Finalization` is now defined in terms of types that need finalization. These types include a variety of language-defined types that *might* be implemented with a controlled type. If the restriction `No_Nested_Finalization` (see D.7) applies to the partition, and one of these language-defined types does not have a controlled part, it will not be allowed in local objects in Ada 2005 whereas it would be allowed in original Ada 95. Such code is not portable, as other Ada compilers may have had a controlled part, and thus would be illegal under the restriction.

Extensions to Ada 95

- 22.b/2 `{AI95-00297-01}` `{AI95-00305-01}` `{AI95-00394-01}` Restrictions `No_Dynamic_Attachment`, `No_Local_Protected_Objects`, `No_Protected_Type_Allocators`, `No_Local_Timing_Events`, `No_Relative_Delay`, `No_Requeue_Statement`, `No_Select_Statements`, `No_Specific_Termination_Handlers`, `No_Task_Termination`, `Max_Entry_Queue_Length`, and `Simple_Barriers` are newly added to Ada.

Wording Changes from Ada 95

- 22.c/2 `{8652/0042}` `{AI95-00130-01}` **Corrigendum:** Clarified that `No_Nested_Finalization` covered task and protected parts as well.
- 22.d/2 `{8652/0076}` `{AI95-00067-01}` **Corrigendum:** Changed the description of `Max_Tasks` and `Max_Asynchronous_Select_Nested` to eliminate conflicts with the High Integrity Annex (see H.4).
- 22.e/2 `{AI95-00327-01}` Added using of the new `Priority` attribute to the restriction `No_Dynamic_Priorities`.
- 22.f/2 `{AI95-00394-01}` Restriction `No_Asynchronous_Control` is now obsolescent.

Incompatibilities With Ada 2005

- 22.g/3 `{AI05-0013-1}` **Correction:** Changed so that coextensions of types that require nested finalization are also prohibited; this is done by prohibiting allocators rather than objects of specific access types. It seems unlikely that any program

depending on this restriction would violate it in this blatant manner, so it is expected that very few programs will be affected by this change.

{AI05-0211-1} **Correction:** The restriction `No_Relative_Delay` was changed to include the `Timing_Events` routine that uses a relative delay. This means that a program that uses that routine and this restriction will now be rejected. However, such a program violates the spirit and intent of the restriction and as such the program should never have been allowed. Moreover, it is unlikely that any program depending on this restriction would violate it in such an obvious manner, so it is expected that very few programs will be affected by this change. 22.h/3

{AI05-0211-1} **Correction:** A number of restrictions were changed from "no calls" on some subprogram to "no use of a name that denotes" that subprogram. This closes a hole where renames, uses as the prefix of 'Access, and the like, would not be rejected by the restriction, possibly allowing backdoor access to the prohibited subprogram. A program that uses one of these restrictions and using such backdoor access will now be rejected; however, it is extremely unlikely that any program that relies on these restrictions would also use an end-run around the restriction, so it is expected that very few programs will be affected by this change. 22.i/3

Extensions to Ada 2005

{AI05-0189-1} Restriction `No_Standard_Allocators_After_Elaboration` is newly added to Ada. 22.j/3

Wording Changes from Ada 2005

{AI05-0013-1} {AI05-0216-1} **Correction:** Improved the wording of various restrictions to make it clearer that they prohibit things that would otherwise be legal, and to word them as definitions, not Legality Rules;. 22.k/3

{AI05-0192-1} **Correction:** Added wording to explain how `No_Task_Allocators` and `No_Protected_Type_Allocators` are checked for class-wide types. This might be an extension if the compiler assumed the worst in the past (it is now a runtime check). 22.l/3

D.8 Monotonic Time

{AI05-0299-1} [This subclause specifies a high-resolution, monotonic clock package.] 1/3

Static Semantics

The following language-defined library package exists: 2

```

package Ada.Real_Time is 3
  type Time is private; 4
  Time_First : constant Time;
  Time_Last : constant Time;
  Time_Unit : constant := implementation-defined-real-number;

  type Time_Span is private; 5
  Time_Span_First : constant Time_Span;
  Time_Span_Last : constant Time_Span;
  Time_Span_Zero : constant Time_Span;
  Time_Span_Unit : constant Time_Span;

  Tick : constant Time_Span; 6
  function Clock return Time;

  function "+" (Left : Time; Right : Time_Span) return Time; 7
  function "+" (Left : Time_Span; Right : Time) return Time;
  function "-" (Left : Time; Right : Time_Span) return Time;
  function "-" (Left : Time; Right : Time) return Time_Span;

  function "<" (Left, Right : Time) return Boolean; 8
  function "<=" (Left, Right : Time) return Boolean;
  function ">" (Left, Right : Time) return Boolean;
  function ">=" (Left, Right : Time) return Boolean;

  function "+" (Left, Right : Time_Span) return Time_Span; 9
  function "-" (Left, Right : Time_Span) return Time_Span;
  function "-" (Right : Time_Span) return Time_Span;
  function "*" (Left : Time_Span; Right : Integer) return Time_Span;
  function "*" (Left : Integer; Right : Time_Span) return Time_Span;
  function "/" (Left, Right : Time_Span) return Integer;
  function "/" (Left : Time_Span; Right : Integer) return Time_Span;

```

```

10     function "abs"(Right : Time_Span) return Time_Span;
11/1   This paragraph was deleted.
12     function "<" (Left, Right : Time_Span) return Boolean;
13     function "<=" (Left, Right : Time_Span) return Boolean;
14     function ">" (Left, Right : Time_Span) return Boolean;
15     function ">=" (Left, Right : Time_Span) return Boolean;
16     function To_Duration (TS : Time_Span) return Duration;
17     function To_Time_Span (D : Duration) return Time_Span;
18/2   {AI95-00386-01} function Nanoseconds (NS : Integer) return Time_Span;
19     function Microseconds (US : Integer) return Time_Span;
20     function Milliseconds (MS : Integer) return Time_Span;
21     function Seconds (S : Integer) return Time_Span;
22     function Minutes (M : Integer) return Time_Span;
23     type Seconds_Count is range implementation-defined;
24     procedure Split(T : in Time; SC : out Seconds_Count; TS : out Time_Span);
25     function Time_Of(SC : Seconds_Count; TS : Time_Span) return Time;
26     private
27     ... -- not specified by the language
28     end Ada.Real_Time;
29/a/2   This paragraph was deleted.

```

In this Annex, *real time* is defined to be the physical time as observed in the external environment. The type `Time` is a *time type* as defined by 9.6; [values of this type may be used in a `delay_until_statement`.] Values of this type represent segments of an ideal time line. The set of values of the type `Time` corresponds one-to-one with an implementation-defined range of mathematical integers.

Discussion: Informally, real time is defined to be the International Atomic Time (TAI) which is monotonic and nondecreasing. We use it here for the purpose of discussing rate of change and monotonic behavior only. It does not imply anything about the absolute value of `Real_Time.Clock`, or about `Real_Time.Time` being synchronized with TAI. It is also used for real time in the metrics, for comparison purposes.

Implementation Note: The specification of TAI as “real time” does not preclude the use of a simulated TAI clock for simulated execution environments.

The `Time` value `I` represents the half-open real time interval that starts with `E+I*Time_Unit` and is limited by `E+(I+1)*Time_Unit`, where `Time_Unit` is an implementation-defined real number and `E` is an unspecified origin point, the *epoch*, that is the same for all values of the type `Time`. It is not specified by the language whether the time values are synchronized with any standard time reference. [For example, `E` can correspond to the time of system initialization or it can correspond to the epoch of some time standard.]

Discussion: `E` itself does not have to be a proper time value.

This half-open interval `I` consists of all real numbers `R` such that `E+I*Time_Unit <= R < E+(I+1)*Time_Unit`.

Values of the type `Time_Span` represent length of real time duration. The set of values of this type corresponds one-to-one with an implementation-defined range of mathematical integers. The `Time_Span` value corresponding to the integer `I` represents the real-time duration `I*Time_Unit`.

Reason: The purpose of this type is similar to `Standard.Duration`; the idea is to have a type with a higher resolution.

Discussion: We looked at many possible names for this type: `Real_Time.Duration`, `Fine_Duration`, `Interval`, `Time_Interval_Length`, `Time_Measure`, and more. Each of these names had some problems, and we've finally settled for `Time_Span`.

`Time_First` and `Time_Last` are the smallest and largest values of the `Time` type, respectively. Similarly, `Time_Span_First` and `Time_Span_Last` are the smallest and largest values of the `Time_Span` type, respectively.

A value of type `Seconds_Count` represents an elapsed time, measured in seconds, since the epoch.

Dynamic Semantics

- Time_Unit is the smallest amount of real time representable by the Time type; it is expressed in seconds. 23
 Time_Span_Unit is the difference between two successive values of the Time type. It is also the smallest positive value of type Time_Span. Time_Unit and Time_Span_Unit represent the same real time duration. A *clock tick* is a real time interval during which the clock value (as observed by calling the Clock function) remains constant. Tick is the average length of such intervals.
- {AI95-00432-01} The function To_Duration converts the value TS to a value of type Duration. Similarly, 24/2
 the function To_Time_Span converts the value D to a value of type Time_Span. For To_Duration, the result is rounded to the nearest value of type Duration (away from zero if exactly halfway between two values). If the result is outside the range of Duration, Constraint_Error is raised. For To_Time_Span, the value of D is first rounded to the nearest integral multiple of Time_Unit, away from zero if exactly halfway between two multiples. If the rounded value is outside the range of Time_Span, Constraint_Error is raised. Otherwise, the value is converted to the type Time_Span.
- To_Duration(Time_Span_Zero) returns 0.0, and To_Time_Span(0.0) returns Time_Span_Zero. 25
- {AI95-00386-01} {AI95-00432-01} The functions Nanoseconds, Microseconds, Milliseconds, Seconds, 26/2
 and Minutes convert the input parameter to a value of the type Time_Span. NS, US, MS, S, and M are interpreted as a number of nanoseconds, microseconds, milliseconds, seconds, and minutes respectively. The input parameter is first converted to seconds and rounded to the nearest integral multiple of Time_Unit, away from zero if exactly halfway between two multiples. If the rounded value is outside the range of Time_Span, Constraint_Error is raised. Otherwise, the rounded value is converted to the type Time_Span.
- This paragraph was deleted.* {AI95-00432-01} 26.a/2
- The effects of the operators on Time and Time_Span are as for the operators defined for integer types. 27
- Implementation Note:** Though time values are modeled by integers, the types Time and Time_Span need not be 27.a
 implemented as integers.
- The function Clock returns the amount of time since the epoch. 28
- The effects of the Split and Time_Of operations are defined as follows, treating values of type Time, 29
 Time_Span, and Seconds_Count as mathematical integers. The effect of Split(T,SC,TS) is to set SC and TS to values such that $T * \text{Time_Unit} = \text{SC} * 1.0 + \text{TS} * \text{Time_Unit}$, and $0.0 \leq \text{TS} * \text{Time_Unit} < 1.0$. The value returned by Time_Of(SC,TS) is the value T such that $T * \text{Time_Unit} = \text{SC} * 1.0 + \text{TS} * \text{Time_Unit}$.
- Implementation Requirements*
- The range of Time values shall be sufficient to uniquely represent the range of real times from program 30
 start-up to 50 years later. Tick shall be no greater than 1 millisecond. Time_Unit shall be less than or equal to 20 microseconds.
- Implementation Note:** The required range and accuracy of Time are such that 32-bits worth of seconds and 32-bits 30.a
 worth of ticks in a second could be used as the representation.
- Time_Span_First shall be no greater than -3600 seconds, and Time_Span_Last shall be no less than 3600 31
 seconds.
- Reason:** This is equivalent to \pm one hour and there is still room for a two-microsecond resolution. 31.a
- A *clock jump* is the difference between two successive distinct values of the clock (as observed by calling 32
 the Clock function). There shall be no backward clock jumps.

Documentation Requirements

- 33 The implementation shall document the values of `Time_First`, `Time_Last`, `Time_Span_First`, `Time_Span_Last`, `Time_Span_Unit`, and `Tick`.
- 33.a/2 **Documentation Requirement:** The values of `Time_First`, `Time_Last`, `Time_Span_First`, `Time_Span_Last`, `Time_Span_Unit`, and `Tick` for package `Real_Time`.
- 34 The implementation shall document the properties of the underlying time base used for the clock and for type `Time`, such as the range of values supported and any relevant aspects of the underlying hardware or operating system facilities used.
- 34.a.1/2 **Documentation Requirement:** The properties of the underlying time base used in package `Real_Time`.
- 34.a **Discussion:** If there is an underlying operating system, this might include information about which system call is used to implement the clock. Otherwise, it might include information about which hardware clock is used.
- 35 The implementation shall document whether or not there is any synchronization with external time references, and if such synchronization exists, the sources of synchronization information, the frequency of synchronization, and the synchronization method applied.
- 35.a.1/2 **Documentation Requirement:** Any synchronization of package `Real_Time` with external time references.
- 36/3 *{AI05-0299-1}* The implementation shall document any aspects of the external environment that could interfere with the clock behavior as defined in this subclause.
- 36.a.1/2 **Documentation Requirement:** Any aspects of the external environment that could interfere with package `Real_Time`.
- 36.a **Discussion:** For example, the implementation is allowed to rely on the time services of an underlying operating system, and this operating system clock can implement time zones or allow the clock to be reset by an operator. This dependence has to be documented.

Metrics

- 37/3 *{AI05-0299-1}* For the purpose of the metrics defined in this subclause, real time is defined to be the International Atomic Time (TAI).
- 38 The implementation shall document the following metrics:
- 39 • An upper bound on the real-time duration of a clock tick. This is a value D such that if t_1 and t_2 are any real times such that $t_1 < t_2$ and $\text{Clock}_{t_1} = \text{Clock}_{t_2}$ then $t_2 - t_1 \leq D$.
- 40 • An upper bound on the size of a clock jump.
- 41 • An upper bound on the *drift rate* of `Clock` with respect to real time. This is a real number D such that
- 42
$$E*(1-D) \leq (\text{Clock}_{t+E} - \text{Clock}_t) \leq E*(1+D)$$
provided that: $\text{Clock}_t + E*(1+D) \leq \text{Time_Last}$.
- 43 • where Clock_t is the value of `Clock` at time t , and E is a real time duration not less than 24 hours. The value of E used for this metric shall be reported.
- 43.a **Reason:** This metric is intended to provide a measurement of the long term (cumulative) deviation; therefore, 24 hours is the lower bound on the measurement period. On some implementations, this is also the maximum period, since the language does not require that the range of the type `Duration` be more than 24 hours. On those implementations that support longer-range `Duration`, longer measurements should be performed.
- 44 • An upper bound on the execution time of a call to the `Clock` function, in processor clock cycles.
- 45 • Upper bounds on the execution times of the operators of the types `Time` and `Time_Span`, in processor clock cycles.
- 45.a **Implementation Note:** A fast implementation of the `Clock` function involves repeated reading until you get the same value twice. It is highly improbable that more than three reads will be necessary. Arithmetic on time values should not be significantly slower than 64-bit arithmetic in the underlying machine instruction set.
- 45.a.1/2 **Documentation Requirement:** The metrics for package `Real_Time`.

Implementation Permissions

Implementations targeted to machines with word size smaller than 32 bits need not support the full range and granularity of the `Time` and `Time_Span` types. 46

Discussion: These requirements are based on machines with a word size of 32 bits. 46.a

Since the range and granularity are implementation defined, the supported values need to be documented. 46.b

Implementation Advice

When appropriate, implementations should provide configuration mechanisms to change the value of `Tick`. 47

Implementation Advice: When appropriate, mechanisms to change the value of `Tick` should be provided. 47.a.1/2

Reason: This is often needed when the compilation system was originally targeted to a particular processor with a particular interval timer, but the customer uses the same processor with a different interval timer. 47.a

Discussion: `Tick` is a deferred constant and not a named number specifically for this purpose. 47.b

Implementation Note: This can be achieved either by pre-run-time configuration tools, or by having `Tick` be initialized (in the package private part) by a function call residing in a board specific module. 47.c

It is recommended that `Calendar.Clock` and `Real_Time.Clock` be implemented as transformations of the same time base. 48

Implementation Advice: `Calendar.Clock` and `Real_Time.Clock` should be transformations of the same time base. 48.a.1/2

It is recommended that the “best” time base which exists in the underlying system be available to the application through `Clock`. “Best” may mean highest accuracy or largest range. 49

Implementation Advice: The “best” time base which exists in the underlying system should be available to the application through `Real_Time.Clock`. 49.a.1/2

NOTES

35 *{AI05-0299-1}* The rules in this subclause do not imply that the implementation can protect the user from operator or installation errors which could result in the clock being set incorrectly. 50/3

36 `Time_Unit` is the granularity of the `Time` type. In contrast, `Tick` represents the granularity of `Real_Time.Clock`. There is no requirement that these be the same. 51

Incompatibilities With Ada 95

{AI95-00386-01} *{AI05-0005-1}* Functions `Seconds` and `Minutes` are added to `Real_Time`. If `Real_Time` is referenced in a `use_clause`, and an entity *E* with a `defining_identifier` of `Seconds` or `Minutes` is defined in a package that is also referenced in a `use_clause`, the entity *E* may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur. 51.a/3

Wording Changes from Ada 95

{AI95-00432-01} Added wording explaining how and when many of these functions can raise `Constraint_Error`. While there always was an intent to raise `Constraint_Error` if the values did not fit, there never was any wording to that effect, and since `Time_Span` was a private type, the normal numeric type rules do not apply to it. 51.b/2

D.9 Delay Accuracy

{AI05-0299-1} [This subclause specifies performance requirements for the `delay_statement`. The rules apply both to `delay_relative_statement` and to `delay_until_statement`. Similarly, they apply equally to a simple `delay_statement` and to one which appears in a `delay_alternative`.] 1/3

Dynamic Semantics

The effect of the `delay_statement` for `Real_Time.Time` is defined in terms of `Real_Time.Clock`: 2

- If C_1 is a value of `Clock` read before a task executes a `delay_relative_statement` with duration *D*, and C_2 is a value of `Clock` read after the task resumes execution following that `delay_statement`, then $C_2 - C_1 \geq D$. 3

- 4 • If C is a value of Clock read after a task resumes execution following a `delay_until_statement` with `Real_Time.Time` value T, then $C \geq T$.

5 A simple `delay_statement` with a negative or zero value for the expiration time does not cause the calling task to be blocked; it is nevertheless a potentially blocking operation (see 9.5.1).

6/3 {AI05-0004-1} When a `delay_statement` appears in a `delay_alternative` of a `timed_entry_call` the selection of the entry call is attempted, regardless of the specified expiration time. When a `delay_statement` appears in a `select_alternative`, and a call is queued on one of the open entries, the selection of that entry call proceeds, regardless of the value of the delay expression.

6.a **Ramification:** The effect of these requirements is that one has to always attempt a rendezvous, regardless of the value of the delay expression. This can be tested by issuing a `timed_entry_call` with an expiration time of zero, to an open entry.

Documentation Requirements

7 The implementation shall document the minimum value of the delay expression of a `delay_relative_statement` that causes the task to actually be blocked.

7.a/2 **Documentation Requirement:** The minimum value of the delay expression of a `delay_relative_statement` that causes a task to actually be blocked.

8 The implementation shall document the minimum difference between the value of the delay expression of a `delay_until_statement` and the value of `Real_Time.Clock`, that causes the task to actually be blocked.

8.a/2 *This paragraph was deleted.*

8.b/2 **Documentation Requirement:** The minimum difference between the value of the delay expression of a `delay_until_statement` and the value of `Real_Time.Clock`, that causes the task to actually be blocked.

Metrics

9 The implementation shall document the following metrics:

- 10 • An upper bound on the execution time, in processor clock cycles, of a `delay_relative_statement` whose requested value of the delay expression is less than or equal to zero.
- 11 • An upper bound on the execution time, in processor clock cycles, of a `delay_until_statement` whose requested value of the delay expression is less than or equal to the value of `Real_Time.Clock` at the time of executing the statement. Similarly, for `Calendar.Clock`.
- 12 • An upper bound on the *lateness* of a `delay_relative_statement`, for a positive value of the delay expression, in a situation where the task has sufficient priority to preempt the processor as soon as it becomes ready, and does not need to wait for any other execution resources. The upper bound is expressed as a function of the value of the delay expression. The *lateness* is obtained by subtracting the value of the delay expression from the *actual duration*. The actual duration is measured from a point immediately before a task executes the `delay_statement` to a point immediately after the task resumes execution following this statement.
- 13 • An upper bound on the *lateness* of a `delay_until_statement`, in a situation where the value of the requested expiration time is after the time the task begins executing the statement, the task has sufficient priority to preempt the processor as soon as it becomes ready, and it does not need to wait for any other execution resources. The upper bound is expressed as a function of the difference between the requested expiration time and the clock value at the time the statement begins execution. The *lateness* of a `delay_until_statement` is obtained by subtracting the requested expiration time from the real time that the task resumes execution following this statement.

13.a/2 **Documentation Requirement:** The metrics for delay statements.

Wording Changes from Ada 83

The rules regarding a `timed_entry_call` with a very small positive `Duration` value, have been tightened to always require the check whether the rendezvous is immediately possible. 14.a

Wording Changes from Ada 95

{AI95-00355-01} The note about “voluntary round-robin”, while still true, has been deleted as potentially confusing as it is describing a different kind of round-robin than is defined by the round-robin dispatching policy. 14.b/2

D.10 Synchronous Task Control

{AI05-0299-1} [This subclause describes a language-defined private semaphore (suspension object), which can be used for *two-stage suspend* operations and as a simple building block for implementing higher-level queues.] 1/3

Static Semantics

The following language-defined package exists: 2

```
{AI95-00362-01} package Ada.Synchronous_Task_Control is 3/2
  pragma Preelaborate(Synchronous_Task_Control);
  type Suspension_Object is limited private; 4
  procedure Set_True(S : in out Suspension_Object);
  procedure Set_False(S : in out Suspension_Object);
  function Current_State(S : Suspension_Object) return Boolean;
  procedure Suspend_Until_True(S : in out Suspension_Object);
private
  ... -- not specified by the language
end Ada.Synchronous_Task_Control;
```

The type `Suspension_Object` is a by-reference type. 5

Implementation Note: {AI95-00318-02} The implementation can ensure this by, for example, making the full view an explicitly limited record type. 5.a/2

{AI05-0168-1} The following language-defined package exists: 5.1/3

```
{AI05-0168-1} package Ada.Synchronous_Task_Control.EDF is 5.2/3
  procedure Suspend_Until_True_And_Set_Deadline
    (S : in out Suspension_Object;
     TS : in Ada.Real_Time.Time_Span);
end Ada.Synchronous_Task_Control.EDF;
```

Dynamic Semantics

{AI95-00114-01} An object of the type `Suspension_Object` has two visible states: `True` and `False`. Upon initialization, its value is set to `False`. 6/2

Discussion: This object is assumed to be private to the declaring task, i.e. only that task will call `Suspend_Until_True` on this object, and the count of callers is at most one. Other tasks can, of course, change and query the state of this object. 6.a

{AI95-00114-01} The operations `Set_True` and `Set_False` are atomic with respect to each other and with respect to `Suspend_Until_True`; they set the state to `True` and `False` respectively. 7/2

`Current_State` returns the current state of the object. 8

Discussion: This state can change immediately after the operation returns. 8.a

{AI95-00114-01} The procedure `Suspend_Until_True` blocks the calling task until the state of the object `S` is `True`; at that point the task becomes ready and the state of the object becomes `False`. 9/2

`Program_Error` is raised upon calling `Suspend_Until_True` if another task is already waiting on that suspension object. `Suspend_Until_True` is a potentially blocking operation (see 9.5.1). 10

- 10.1/3 {AI05-0168-1} {AI05-0269-1} The procedure `Suspend_Until_True_And_Set_Deadline` blocks the calling task until the state of the object `S` is `True`; at that point the task becomes ready with a deadline of `Ada.Real_Time.Clock + TS`, and the state of the object becomes `False`. `Program_Error` is raised upon calling `Suspend_Until_True_And_Set_Deadline` if another task is already waiting on that suspension object. `Suspend_Until_True_And_Set_Deadline` is a potentially blocking operation.

Implementation Requirements

- 11 The implementation is required to allow the calling of `Set_False` and `Set_True` during any protected action, even one that has its ceiling priority in the `Interrupt_Priority` range.

NOTES

- 12/3 37 {AI05-0168-1} More complex schemes, such as setting the deadline relative to when `Set_True` is called, can be programmed using a protected object.

Extensions to Ada 95

- 12.a/2 {AI95-00362-01} `Synchronous_Task_Control` is now `Preelaborated`, so it can be used in `preelaborated` units.

Extensions to Ada 2005

- 12.b/3 {AI05-0168-1} Child package `Ada.Synchronous_Task_Control.EDF` is new.

D.10.1 Synchronous Barriers

- 1/3 {AI05-0174-1} {AI05-0299-1} This subclause introduces a language-defined package to synchronously release a group of tasks after the number of blocked tasks reaches a specified count value.

Static Semantics

- 2/3 {AI05-0174-1} The following language-defined library package exists:
- 3/3 **package** `Ada.Synchronous_Barriers` **is**
 pragma `Preelaborate(Synchronous_Barriers)` ;
- 4/3 **subtype** `Barrier_Limit` **is** `Positive` **range** `1 .. implementation-defined` ;
- 4.a.1/3 **Implementation defined:** The value of `Barrier_Limit'Last` in `Synchronous_Barriers`.
- 5/3 **type** `Synchronous_Barrier` (`Release_Threshold` : `Barrier_Limit`) **is limited private** ;
- 6/3 **procedure** `Wait_For_Release` (`The_Barrier` : **in out** `Synchronous_Barrier` ;
 `Notified` : **out** `Boolean`) ;
- 7/3 **private**
 -- *not specified by the language*
end `Ada.Synchronous_Barriers` ;
- 8/3 {AI05-0174-1} Type `Synchronous_Barrier` needs finalization (see 7.6).

Dynamic Semantics

- 9/3 {AI05-0174-1} Each call to `Wait_For_Release` blocks the calling task until the number of blocked tasks associated with the `Synchronous_Barrier` object is equal to `Release_Threshold`, at which time all blocked tasks are released. `Notified` is set to `True` for one of the released tasks, and set to `False` for all other released tasks.
- 10/3 {AI05-0174-1} The mechanism for determining which task sets `Notified` to `True` is implementation defined.
- 11/3 {AI05-0174-1} Once all tasks have been released, a `Synchronous_Barrier` object may be reused to block another `Release_Threshold` number of tasks.
- 12/3 {AI05-0174-1} As the first step of the finalization of a `Synchronous_Barrier`, each blocked task is unblocked and `Program_Error` is raised at the place of the call to `Wait_For_Release`.

{AI05-0174-1} It is implementation defined whether an abnormal task which is waiting on a Synchronous_Barrier object is aborted immediately or aborted when the tasks waiting on the object are released. 13/3

Implementation defined: When an aborted task that is waiting on a Synchronous_Barrier is aborted. 13.a.1/3

{AI05-0174-1} Wait_For_Release is a potentially blocking operation (see 9.5.1). 14/3

Bounded (Run-Time) Errors

{AI05-0174-1} It is a bounded error to call Wait_For_Release on a Synchronous_Barrier object after that object is finalized. If the error is detected, Program_Error is raised. Otherwise, the call proceeds normally, which may leave a task blocked forever. 15/3

Extensions to Ada 2005

{AI05-0174-1} The package Ada.Synchronous_Barriers is new. 15.a/3

D.11 Asynchronous Task Control

{AI05-0299-1} [This subclause introduces a language-defined package to do asynchronous suspend/resume on tasks. It uses a conceptual *held priority* value to represent the task's *held* state.] 1/3

Static Semantics

The following language-defined library package exists: 2

```
{AI95-00362-01} with Ada.Task_Identification;
package Ada.Asynchronous_Task_Control is
  pragma Preelaborate(Asynchronous_Task_Control);
  procedure Hold(T : in Ada.Task_Identification.Task_Id);
  procedure Continue(T : in Ada.Task_Identification.Task_Id);
  function Is_Held(T : Ada.Task_Identification.Task_Id)
    return Boolean;
end Ada.Asynchronous_Task_Control;
```

3/2

Dynamic Semantics

{AI95-00357-01} After the Hold operation has been applied to a task, the task becomes *held*. For each processor there is a conceptual *idle task*, which is always ready. The base priority of the idle task is below System.Any_Priority'First. The *held priority* is a constant of the type Integer whose value is below the base priority of the idle task. 4/2

Discussion: The held state should not be confused with the blocked state as defined in 9.2; the task is still ready. 4.a

{AI95-00357-01} For any priority below System.Any_Priority'First, the task dispatching policy is FIFO_Within_Priorities. 4.1/2

To be honest: This applies even if a Task_Dispatching_Policy specifies the policy for all of the priorities of the partition. 4.b/2

Ramification: A task at the held priority never runs, so it is not necessary to implement FIFO_Within_Priorities for systems that have only one policy (such as EDF_Across_Priorities). 4.c/2

{AI95-00357-01} The Hold operation sets the state of T to held. For a held task, the active priority is reevaluated as if the base priority of the task were the held priority. 5/2

Ramification: For example, if T is currently inheriting priorities from other sources (e.g. it is executing in a protected action), its active priority does not change, and it continues to execute until it leaves the protected action. 5.a

{AI95-00357-01} The Continue operation resets the state of T to not-held; its active priority is then reevaluated as determined by the task dispatching policy associated with its base priority. 6/2

The Is_Held function returns True if and only if T is in the held state. 7

7.a **Discussion:** Note that the state of T can be changed immediately after Is_Held returns.

8 As part of these operations, a check is made that the task identified by T is not terminated. Tasking_Error is raised if the check fails. Program_Error is raised if the value of T is Null_Task_Id.

Erroneous Execution

9 If any operation in this package is called with a parameter T that specifies a task object that no longer exists, the execution of the program is erroneous.

Implementation Permissions

10 An implementation need not support Asynchronous_Task_Control if it is infeasible to support it in the target environment.

10.a **Reason:** A direct implementation of the Asynchronous_Task_Control semantics using priorities is not necessarily efficient enough. Thus, we envision implementations that use some other mechanism to set the “held” state. If there is no other such mechanism, support for Asynchronous_Task_Control might be infeasible, because an implementation in terms of priority would require one idle task per processor. On some systems, programs are not supposed to know how many processors are available, so creating enough idle tasks would be problematic.

NOTES

11 38 It is a consequence of the priority rules that held tasks cannot be dispatched on any processor in a partition (unless they are inheriting priorities) since their priorities are defined to be below the priority of any idle task.

12 39 The effect of calling Get_Priority and Set_Priority on a Held task is the same as on any other task.

13 40 Calling Hold on a held task or Continue on a non-held task has no effect.

14 41 The rules affecting queuing are derived from the above rules, in addition to the normal priority rules:

15 • When a held task is on the ready queue, its priority is so low as to never reach the top of the queue as long as there are other tasks on that queue.

16 • If a task is executing in a protected action, inside a rendezvous, or is inheriting priorities from other sources (e.g. when activated), it continues to execute until it is no longer executing the corresponding construct.

17 • If a task becomes held while waiting (as a caller) for a rendezvous to complete, the active priority of the accepting task is not affected.

18/1 • {8652/0077} {AI95-00111-01} If a task becomes held while waiting in a selective_accept, and an entry call is issued to one of the open entries, the corresponding accept_alternative executes. When the rendezvous completes, the active priority of the accepting task is lowered to the held priority (unless it is still inheriting from other sources), and the task does not execute until another Continue.

19 • The same holds if the held task is the only task on a protected entry queue whose barrier becomes open. The corresponding entry body executes.

Extensions to Ada 95

19.a/2 {AI95-00362-01} Asynchronous_Task_Control is now Preelaborated, so it can be used in preelaborated units.

Wording Changes from Ada 95

19.b/2 {8652/0077} {AI95-00111-01} **Corrigendum:** Corrected to eliminate the use of the undefined term “accept body”.

19.c/2 {AI95-00357-01} The description of held tasks was changed to reflect that the calculation of active priorities depends on the dispatching policy of the base priority. Thus, the policy of the held priority was specified in order to avoid surprises (especially when using the EDF policy).

D.12 Other Optimizations and Determinism Rules

1/3 {AI05-0299-1} [This subclause describes various requirements for improving the response and determinism in a real-time system.]

Implementation Requirements

2 If the implementation blocks interrupts (see C.3) not as a result of direct user action (e.g. an execution of a protected action) there shall be an upper bound on the duration of this blocking.

Ramification: The implementation shall not allow itself to be interrupted when it is in a state where it is unable to support all the language-defined operations permitted in the execution of interrupt handlers. (see 9.5.1). 2.a

The implementation shall recognize entry-less protected types. The overhead of acquiring the execution resource of an object of such a type (see 9.5.1) shall be minimized. In particular, there should not be any overhead due to evaluating `entry_barrier` conditions. 3

Implementation Note: Ideally the overhead should just be a spin-lock. 3.a

`Unchecked_Deallocation` shall be supported for terminated tasks that are designated by access types, and shall have the effect of releasing all the storage associated with the task. This includes any run-time system or heap storage that has been implicitly allocated for the task by the implementation. 4

Documentation Requirements

The implementation shall document the upper bound on the duration of interrupt blocking caused by the implementation. If this is different for different interrupts or interrupt priority levels, it should be documented for each case. 5

This paragraph was deleted. 5.a/2

Documentation Requirement: The upper bound on the duration of interrupt blocking caused by the implementation. 5.b/2

Metrics

The implementation shall document the following metric: 6

- The overhead associated with obtaining a mutual-exclusive access to an entry-less protected object. This shall be measured in the following way: 7

For a protected object of the form: 8

```

protected Lock is
  procedure Set;
  function Read return Boolean;
private
  Flag : Boolean := False;
end Lock;
protected body Lock is
  procedure Set is
  begin
    Flag := True;
  end Set;
  function Read return Boolean
  begin
    return Flag;
  end Read;
end Lock;

```

9
10

The execution time, in processor clock cycles, of a call to `Set`. This shall be measured between the point just before issuing the call, and the point just after the call completes. The function `Read` shall be called later to verify that `Set` was indeed called (and not optimized away). The calling task shall have sufficiently high priority as to not be preempted during the measurement period. The protected object shall have sufficiently high ceiling priority to allow the task to call `Set`. 11

For a multiprocessor, if supported, the metric shall be reported for the case where no contention (on the execution resource) exists [from tasks executing on other processors]. 12

Documentation Requirement: The metrics for entry-less protected objects. 12.a/2

D.13 The Ravenscar Profile

{AI95-00249-01} {AI05-0246-1} {AI05-0299-1} [This subclause defines the Ravenscar profile.] 1/3

Paragraphs 2 and 3 were moved to 13.12, "Pragma Restrictions and Pragma Profile".

Legality Rules

- 4/3 {AI95-00249-01} {AI05-0246-1} The *profile_identifier* Ravenscar is a usage profile (see 13.12). For usage profile Ravenscar, there shall be no *profile_pragma_argument_associations*.

Static Semantics

- 5/3 {AI95-00249-01} {AI05-0246-1} The usage profile Ravenscar is equivalent to the following set of pragmas:

- 6/3 {AI95-00249-01} {AI95-00297-01} {AI95-00394-01} {AI05-0171-1} {AI05-0246-1} **pragma** Task_Dispatching_Policy (FIFO_Within_Priorities);
pragma Locking_Policy (Ceiling_Locking);
pragma Detect_Blocking;
pragma Restrictions (
 No_Abort_Statements,
 No_Dynamic_Attachment,
 No_Dynamic_Priorities,
 No_Implicit_Heap_Allocations,
 No_Local_Protected_Objects,
 No_Local_Timing_Events,
 No_Protected_Type_Allocators,
 No_Relative_Delay,
 No_Requeue_Statements,
 No_Select_Statements,
 No_Specific_Termination_Handlers,
 No_Task_Allocators,
 No_Task_Hierarchy,
 No_Task_Termination,
 Simple_Barriers,
 Max_Entry_Queue_Length => 1,
 Max_Protected_Entries => 1,
 Max_Task_Entries => 0,
 No_Dependence => Ada.Asynchronous_Task_Control,
 No_Dependence => Ada.Calendar,
 No_Dependence => Ada.Execution_Time.Group_Budgets,
 No_Dependence => Ada.Execution_Time.Timers,
 No_Dependence => Ada.Task_Attributes,
 No_Dependence => System.Multiprocessors.Dispatching_Domains);

- 6.a/3 **Discussion:** The Ravenscar profile is named for the location of the meeting that defined its initial version. The name is now in widespread use, so we stick with existing practice, rather than using a more descriptive name.

Paragraph 7 was deleted.

Implementation Requirements

- 8/3 {AI05-0171-1} {AI05-0229-1} A task shall only be on the ready queues of one processor, and the processor to which a task belongs shall be defined statically. Whenever a task running on a processor reaches a task dispatching point, it goes back to the ready queues of the same processor. A task with a CPU value of Not_A_Specific_CPU will execute on an implementation defined processor. [A task without a CPU aspect will activate and execute on the same processor as its activating task.]
- 8.a/3 **Proof:** The processor of a task without a CPU aspect is defined in D.16.
- 8.a.1/3 **Implementation defined:** The processor on which a task with a CPU value of a Not_A_Specific_CPU will execute when the Ravenscar profile is in effect.

Implementation Advice

- 9/3 {AI05-0171-1} On a multiprocessor system, an implementation should support a fully partitioned approach. Each processor should have separate and disjoint ready queues.
- 9.a.1/3 **Implementation Advice:** On a multiprocessor system, each processor should have a separate and disjoint ready queue.

NOTES

42 {AI95-00249-01} {AI05-0246-1} The effect of the Max_Entry_Queue_Length => 1 restriction applies only to protected entry queues due to the accompanying restriction of Max_Task_Entries => 0. 10/3

Extensions to Ada 95

{AI95-00249-01} {AI05-0246-1} The Ravenscar profile is new; it was moved here by Ada 2012. 10.a/3

Wording Changes from Ada 2005

{AI05-0171-1} How Ravenscar behaves on a multiprocessor system is now defined. 10.b/3

D.14 Execution Time

{AI95-00307-01} {AI05-0299-1} This subclause describes a language-defined package to measure execution time. 1/3

Static Semantics

{AI95-00307-01} The following language-defined library package exists: 2/2

```

with Ada.Task_Identification;
with Ada.Real_Time; use Ada.Real_Time;
package Ada.Execution_Time is
  type CPU_Time is private;
  CPU_Time_First : constant CPU_Time;
  CPU_Time_Last  : constant CPU_Time;
  CPU_Time_Unit  : constant := implementation-defined-real-number;
  CPU_Tick       : constant Time_Span;

  function Clock
    (T : Ada.Task_Identification.Task_Id
     := Ada.Task_Identification.Current_Task)
    return CPU_Time;

  function "+" (Left : CPU_Time; Right : Time_Span) return CPU_Time;
  function "+" (Left : Time_Span; Right : CPU_Time) return CPU_Time;
  function "-" (Left : CPU_Time; Right : Time_Span) return CPU_Time;
  function "-" (Left : CPU_Time; Right : CPU_Time) return Time_Span;

  function "<" (Left, Right : CPU_Time) return Boolean;
  function "<=" (Left, Right : CPU_Time) return Boolean;
  function ">" (Left, Right : CPU_Time) return Boolean;
  function ">=" (Left, Right : CPU_Time) return Boolean;

  procedure Split
    (T : in CPU_Time; SC : out Seconds_Count; TS : out Time_Span);

  function Time_Of (SC : Seconds_Count;
                  TS : Time_Span := Time_Span_Zero) return CPU_Time;

  {AI05-0170-1} Interrupt_Clocks_Supported : constant Boolean := implementation-defined;
  {AI05-0170-1} Separate_Interrupt_Clocks_Supported : constant Boolean :=
    implementation-defined;
  {AI05-0170-1} function Clock_For_Interrupts return CPU_Time;

private
  ... -- not specified by the language
end Ada.Execution_Time;

```

{AI95-00307-01} {AI05-0170-1} {AI05-0269-1} The *execution time* or CPU time of a given task is defined as the time spent by the system executing that task, including the time spent executing run-time or system services on its behalf. The mechanism used to measure execution time is implementation defined. The Boolean constant Interrupt_Clocks_Supported is set to True if the implementation separately accounts for the execution time of interrupt handlers. If it is set to False it is implementation defined which task, if any, is charged the execution time that is consumed by interrupt handlers. The Boolean

constant `Separate_Interrupt_Clocks_Supported` is set to `True` if the implementation separately accounts for the execution time of individual interrupt handlers (see D.14.3).

- 11.a/2 **Discussion:** The implementation-defined properties above and of the values declared in the package are repeated in Documentation Requirements, so we don't mark them as implementation-defined.
- 12/2 {AI95-00307-01} The type `CPU_Time` represents the execution time of a task. The set of values of this type corresponds one-to-one with an implementation-defined range of mathematical integers.
- 13/2 {AI95-00307-01} The `CPU_Time` value `I` represents the half-open execution-time interval that starts with `I*CPU_Time_Unit` and is limited by `(I+1)*CPU_Time_Unit`, where `CPU_Time_Unit` is an implementation-defined real number. For each task, the execution time value is set to zero at the creation of the task.
- 13.a/2 **Ramification:** Since it is implementation-defined which task is charged execution time for system services, the execution time value may become nonzero even before the start of the activation of the task.
- 14/2 {AI95-00307-01} `CPU_Time_First` and `CPU_Time_Last` are the smallest and largest values of the `CPU_Time` type, respectively.
- 14.1/3 {AI05-0170-1} The execution time value for the function `Clock_For_Interrupts` is initialized to zero.

Dynamic Semantics

- 15/2 {AI95-00307-01} `CPU_Time_Unit` is the smallest amount of execution time representable by the `CPU_Time` type; it is expressed in seconds. A *CPU clock tick* is an execution time interval during which the clock value (as observed by calling the `Clock` function) remains constant. `CPU_Tick` is the average length of such intervals.
- 16/2 {AI95-00307-01} The effects of the operators on `CPU_Time` and `Time_Span` are as for the operators defined for integer types.
- 17/2 {AI95-00307-01} The function `Clock` returns the current execution time of the task identified by `T`; `Tasking_Error` is raised if that task has terminated; `Program_Error` is raised if the value of `T` is `Task_Identification.Null_Task_Id`.
- 18/2 {AI95-00307-01} The effects of the `Split` and `Time_Of` operations are defined as follows, treating values of type `CPU_Time`, `Time_Span`, and `Seconds_Count` as mathematical integers. The effect of `Split` (`T`, `SC`, `TS`) is to set `SC` and `TS` to values such that $T * CPU_Time_Unit = SC * 1.0 + TS * CPU_Time_Unit$, and $0.0 \leq TS * CPU_Time_Unit < 1.0$. The value returned by `Time_Of`(`SC`,`TS`) is the execution-time value `T` such that $T * CPU_Time_Unit = SC * 1.0 + TS * CPU_Time_Unit$.
- 18.1/3 {AI05-0170-1} The function `Clock_For_Interrupts` returns the total cumulative time spent executing within all interrupt handlers. This time is not allocated to any task execution time clock. If `Interrupt_Clocks_Supported` is set to `False` the function raises `Program_Error`.

Erroneous Execution

- 19/2 {AI95-00307-01} For a call of `Clock`, if the task identified by `T` no longer exists, the execution of the program is erroneous.

Implementation Requirements

- 20/2 {AI95-00307-01} The range of `CPU_Time` values shall be sufficient to uniquely represent the range of execution times from the task start-up to 50 years of execution time later. `CPU_Tick` shall be no greater than 1 millisecond.

Documentation Requirements

{AI95-00307-01} The implementation shall document the values of CPU_Time_First, CPU_Time_Last, CPU_Time_Unit, and CPU_Tick. 21/2

Documentation Requirement: The values of CPU_Time_First, CPU_Time_Last, CPU_Time_Unit, and CPU_Tick of package Execution_Time. 21.a/2

{AI95-00307-01} The implementation shall document the properties of the underlying mechanism used to measure execution times, such as the range of values supported and any relevant aspects of the underlying hardware or operating system facilities used. 22/2

Documentation Requirement: The properties of the mechanism used to implement package Execution_Time, including the values of the constants defined in the package. 22.a/3

Metrics

{AI95-00307-01} The implementation shall document the following metrics: 23/2

- An upper bound on the execution-time duration of a clock tick. This is a value D such that if t_1 and t_2 are any execution times of a given task such that $t_1 < t_2$ and $\text{Clock}_{t_1} = \text{Clock}_{t_2}$ then $t_2 - t_1 \leq D$. 24/2
- An upper bound on the size of a clock jump. A clock jump is the difference between two successive distinct values of an execution-time clock (as observed by calling the Clock function with the same Task_Id). 25/2
- An upper bound on the execution time of a call to the Clock function, in processor clock cycles. 26/2
- Upper bounds on the execution times of the operators of the type CPU_Time, in processor clock cycles. 27/2

Documentation Requirement: The metrics for execution time. 27.a/2

Implementation Permissions

{AI95-00307-01} Implementations targeted to machines with word size smaller than 32 bits need not support the full range and granularity of the CPU_Time type. 28/2

Implementation Advice

{AI95-00307-01} When appropriate, implementations should provide configuration mechanisms to change the value of CPU_Tick. 29/2

Implementation Advice: When appropriate, implementations should provide configuration mechanisms to change the value of Execution_Time.CPU_Tick. 29.a/2

Extensions to Ada 95

{AI95-00307-01} The package Execution_Time is new. 29.b/2

Incompatibilities With Ada 2005

{AI05-0170-1} Function Clock_For_Interrupts, and constants Interrupt_Clocks_Supported and Separate_Interrupt_Clocks_Supported are added to Execution_Time. If Execution_Time is referenced in a use_clause, and an entity E with a defining_identifier of one of the added entities is defined in a package that is also referenced in a use_clause, the entity E may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur. 29.c/3

Wording Changes from Ada 2005

{AI05-0170-1} If Interrupt_Clocks_Supported is True, it is now possible to determine the execution time of interrupt handlers. This is not an inconsistency, as not charging any task for such time was a legitimate implementation for Ada 2005. 29.d/3

D.14.1 Execution Time Timers

1/3 {AI95-00307-01} {AI05-0299-1} This subclause describes a language-defined package that provides a facility for calling a handler when a task has used a defined amount of CPU time.

Static Semantics

2/2 {AI95-00307-01} The following language-defined library package exists:

```
3/2   with System;
      package Ada.Execution_Time.Timers is
4/2       type Timer (T : not null access constant
                    Ada.Task_Identification.Task_Id) is
          tagged limited private;
5/2       type Timer_Handler is
          access protected procedure (TM : in out Timer);
6/2       Min_Handler_Ceiling : constant System.Any_Priority :=
          implementation-defined;
7/2       procedure Set_Handler (TM      : in out Timer;
                                In_Time : in Time_Span;
                                Handler : in Timer_Handler);
          procedure Set_Handler (TM      : in out Timer;
                                At_Time  : in CPU_Time;
                                Handler  : in Timer_Handler);
          function Current_Handler (TM : Timer) return Timer_Handler;
          procedure Cancel_Handler (TM      : in out Timer;
                                    Cancelled : out Boolean);
8/2       function Time_Remaining (TM : Timer) return Time_Span;
9/2       Timer_Resource_Error : exception;
10/2      private
          ... -- not specified by the language
      end Ada.Execution_Time.Timers;
```

11/2 {AI95-00307-01} The type `Timer` represents an execution-time event for a single task and is capable of detecting execution-time overruns. The access discriminant `T` identifies the task concerned. The type `Timer` needs finalization (see 7.6).

12/2 {AI95-00307-01} An object of type `Timer` is said to be *set* if it is associated with a nonnull value of type `Timer_Handler` and *cleared* otherwise. All `Timer` objects are initially cleared.

13/2 {AI95-00307-01} The type `Timer_Handler` identifies a protected procedure to be executed by the implementation when the timer expires. Such a protected procedure is called a *handler*.

13.a/2 **Discussion:** Type `Timer` is tagged. This makes it possible to share a handler between several events. In simple cases, 'Access can be used to compare the parameter with a specific timer object (this works because a tagged type is a by-reference type). In more complex cases, a type extension of type `Timer` can be declared; a double type conversion can be used to access the extension data. An example of how this can be done can be found for the similar type `Timing_Event`, see D.15.

Dynamic Semantics

14/2 {AI95-00307-01} When a `Timer` object is created, or upon the first call of a `Set_Handler` procedure with the timer as parameter, the resources required to operate an execution-time timer based on the associated execution-time clock are allocated and initialized. If this operation would exceed the available resources, `Timer_Resource_Error` is raised.

15/3 {AI95-00307-01} {AI05-0264-1} The procedures `Set_Handler` associate the handler `Handler` with the timer `TM`: if `Handler` is `null`, the timer is cleared; otherwise, it is set. The first procedure `Set_Handler` loads the timer `TM` with an interval specified by the `Time_Span` parameter. In this mode, the timer `TM`

expires when the execution time of the task identified by `TM.T.all` has increased by `In_Time`; if `In_Time` is less than or equal to zero, the timer expires immediately. The second procedure `Set_Handler` loads the timer `TM` with the absolute value specified by `At_Time`. In this mode, the timer `TM` expires when the execution time of the task identified by `TM.T.all` reaches `At_Time`; if the value of `At_Time` has already been reached when `Set_Handler` is called, the timer expires immediately.

- Implementation Note:** Since an access-to-constant can designate a variable, the `Task_Id` value designated by the discriminant of a Timer object can be changed after the object is created. Thus, an implementation cannot use the value of the `Task_Id` other than where this Standard specifies. For instance, the `Task_Id` should be read when the timer is set, but it should not be used when the timer expires (as it may designate a different task at that point). 15.a/2
- {AI95-00307-01} A call of a procedure `Set_Handler` for a timer that is already set replaces the handler and the (absolute or relative) execution time; if `Handler` is not `null`, the timer remains set. 16/2
- {AI95-00307-01} When a timer expires, the associated handler is executed, passing the timer as parameter. The initial action of the execution of the handler is to clear the event. 17/2
- {AI95-00307-01} {AI05-0264-1} The function `Current_Handler` returns the handler associated with the timer `TM` if that timer is set; otherwise, it returns `null`. 18/3
- {AI95-00307-01} {AI05-0264-1} The procedure `Cancel_Handler` clears the timer if it is set. `Cancelled` is assigned `True` if the timer was set prior to it being cleared; otherwise, it is assigned `False`. 19/3
- {AI95-00307-01} {AI05-0264-1} The function `Time_Remaining` returns the execution time interval that remains until the timer `TM` would expire, if that timer is set; otherwise, it returns `Time_Span_Zero`. 20/3
- {AI95-00307-01} The constant `Min_Handler_Ceiling` is the minimum ceiling priority required for a protected object with a handler to ensure that no ceiling violation will occur when that handler is invoked. 21/2
- {AI95-00307-01} As part of the finalization of an object of type `Timer`, the timer is cleared. 22/2
- {AI95-00307-01} For all the subprograms defined in this package, `Tasking_Error` is raised if the task identified by `TM.T.all` has terminated, and `Program_Error` is raised if the value of `TM.T.all` is `Task_Identification.Null_Task_Id`. 23/2
- {AI95-00307-01} An exception propagated from a handler invoked as part of the expiration of a timer has no effect. 24/2

Erroneous Execution

- {AI95-00307-01} For a call of any of the subprograms defined in this package, if the task identified by `TM.T.all` no longer exists, the execution of the program is erroneous. 25/2

Implementation Requirements

- {AI95-00307-01} For a given `Timer` object, the implementation shall perform the operations declared in this package atomically with respect to any of these operations on the same `Timer` object. The replacement of a handler by a call of `Set_Handler` shall be performed atomically with respect to the execution of the handler. 26/2

- Reason:** This prevents various race conditions. In particular it ensures that if an event occurs when `Set_Handler` is changing the handler then either the new or old handler is executed in response to the appropriate event. It is never possible for a new handler to be executed in response to an old event 26.a/2
- {AI95-00307-01} When an object of type `Timer` is finalized, the system resources used by the timer shall be deallocated. 27/2

Implementation Permissions

28/3 {AI95-00307-01} {AI05-0264-1} Implementations may limit the number of timers that can be defined for each task. If this limit is exceeded, then `Timer_Resource_Error` is raised.

NOTES

29/2 43 {AI95-00307-01} A `Timer_Handler` can be associated with several `Timer` objects.

Extensions to Ada 95

29.a/2 {AI95-00307-01} The package `Execution_Time.Timers` is new.

D.14.2 Group Execution Time Budgets

1/3 {AI95-00354-01} {AI05-0299-1} This subclause describes a language-defined package to assign execution time budgets to groups of tasks.

Static Semantics

2/2 {AI95-00354-01} The following language-defined library package exists:

```

3/3 {AI05-0169-1} with System;
with System.Multiprocessors;
package Ada.Execution_Time.Group_Budgets is
4/3 {AI05-0092-1} {AI05-0169-1}   type Group_Budget (CPU : System.Multiprocessors.CPU :=
                                System.Multiprocessors.CPU'First)
                                is tagged limited private;
5/2   type Group_Budget_Handler is access
      protected procedure (GB : in out Group_Budget);
6/2   type Task_Array is array (Positive range <>) of
      Ada.Task_Identification.Task_Id;
7/2   Min_Handler_Ceiling : constant System.Any_Priority :=
      implementation-defined;
7.a.1/3   Implementation defined: The value of Min_Handler_Ceiling in Execution_Time.Group_Budgets.
8/2   procedure Add_Task (GB : in out Group_Budget;
                        T   : in Ada.Task_Identification.Task_Id);
      procedure Remove_Task (GB: in out Group_Budget;
                            T   : in Ada.Task_Identification.Task_Id);
      function Is_Member (GB : Group_Budget;
                        T   : Ada.Task_Identification.Task_Id) return Boolean;
      function Is_A_Group_Member
        (T : Ada.Task_Identification.Task_Id) return Boolean;
      function Members (GB : Group_Budget) return Task_Array;
9/2   procedure Replenish (GB : in out Group_Budget; To : in Time_Span);
      procedure Add (GB : in out Group_Budget; Interval : in Time_Span);
      function Budget_Has_Expired (GB : Group_Budget) return Boolean;
      function Budget_Remaining (GB : Group_Budget) return Time_Span;
10/2   procedure Set_Handler (GB           : in out Group_Budget;
                             Handler      : in Group_Budget_Handler);
      function Current_Handler (GB : Group_Budget)
        return Group_Budget_Handler;
      procedure Cancel_Handler (GB           : in out Group_Budget;
                               Cancelled    : out Boolean);
11/2   Group_Budget_Error : exception;
12/2   private
      -- not specified by the language
      end Ada.Execution_Time.Group_Budgets;

```

13/2 {AI95-00354-01} The type `Group_Budget` represents an execution time budget to be used by a group of tasks. The type `Group_Budget` needs finalization (see 7.6). A task can belong to at most one group. Tasks of any priority can be added to a group.

- {AI95-00354-01} An object of type `Group_Budget` has an associated nonnegative value of type `Time_Span` known as its *budget*, which is initially `Time_Span_Zero`. The type `Group_Budget_Handler` identifies a protected procedure to be executed by the implementation when the budget is *exhausted*, that is, reaches zero. Such a protected procedure is called a *handler*. 14/2
- {AI95-00354-01} An object of type `Group_Budget` also includes a handler, which is a value of type `Group_Budget_Handler`. The handler of the object is said to be *set* if it is not null and *cleared* otherwise. The handler of all `Group_Budget` objects is initially cleared. 15/2
- Discussion:** Type `Group_Budget` is tagged. This makes it possible to share a handler between several events. In simple cases, 'Access can be used to compare the parameter with a specific group budget object (this works because a tagged type is a by-reference type). In more complex cases, a type extension of type `Group_Budget` can be declared; a double type conversion can be used to access the extension data. An example of how this can be done can be found for the similar type `Timing_Event`, see D.15. 15.a/2
- Dynamic Semantics*
- {AI95-00354-01} The procedure `Add_Task` adds the task identified by `T` to the group `GB`; if that task is already a member of some other group, `Group_Budget_Error` is raised. 16/2
- {AI95-00354-01} The procedure `Remove_Task` removes the task identified by `T` from the group `GB`; if that task is not a member of the group `GB`, `Group_Budget_Error` is raised. After successful execution of this procedure, the task is no longer a member of any group. 17/2
- {AI95-00354-01} {AI05-0264-1} The function `Is_Member` returns `True` if the task identified by `T` is a member of the group `GB`; otherwise, it returns `False`. 18/3
- {AI95-00354-01} {AI05-0264-1} The function `Is_A_Group_Member` returns `True` if the task identified by `T` is a member of some group; otherwise, it returns `False`. 19/3
- {AI95-00354-01} The function `Members` returns an array of values of type `Task_Identification.Task_Id` identifying the members of the group `GB`. The order of the components of the array is unspecified. 20/2
- {AI95-00354-01} {AI05-0092-1} {AI05-0169-1} The procedure `Replenish` loads the group budget `GB` with `To` as the `Time_Span` value. The exception `Group_Budget_Error` is raised if the `Time_Span` value `To` is nonpositive. Any execution on CPU of any member of the group of tasks results in the budget counting down, unless exhausted. When the budget becomes exhausted (reaches `Time_Span_Zero`), the associated handler is executed if the handler of group budget `GB` is set. Nevertheless, the tasks continue to execute. 21/3
- {AI95-00354-01} The procedure `Add` modifies the budget of the group `GB`. A positive value for `Interval` increases the budget. A negative value for `Interval` reduces the budget, but never below `Time_Span_Zero`. A zero value for `Interval` has no effect. A call of procedure `Add` that results in the value of the budget going to `Time_Span_Zero` causes the associated handler to be executed if the handler of the group budget `GB` is set. 22/2
- {AI95-00354-01} {AI05-0264-1} The function `Budget_Has_Expired` returns `True` if the budget of group `GB` is exhausted (equal to `Time_Span_Zero`); otherwise, it returns `False`. 23/3
- {AI95-00354-01} The function `Budget_Remaining` returns the remaining budget for the group `GB`. If the budget is exhausted it returns `Time_Span_Zero`. This is the minimum value for a budget. 24/2
- {AI95-00354-01} {AI05-0264-1} The procedure `Set_Handler` associates the handler `Handler` with the `Group_Budget` `GB`: if `Handler` is **null**, the handler of `Group_Budget` is cleared; otherwise, it is set. 25/3
- {AI95-00354-01} A call of `Set_Handler` for a `Group_Budget` that already has a handler set replaces the handler; if `Handler` is not **null**, the handler for `Group_Budget` remains set. 26/2

- 27/3 {AI95-00354-01} {AI05-0264-1} The function `Current_Handler` returns the handler associated with the group budget GB if the handler for that group budget is set; otherwise, it returns **null**.
- 28/3 {AI95-00354-01} {AI05-0264-1} The procedure `Cancel_Handler` clears the handler for the group budget if it is set. `Cancelled` is assigned True if the handler for the group budget was set prior to it being cleared; otherwise, it is assigned False.
- 29/2 {AI95-00354-01} The constant `Min_Handler_Ceiling` is the minimum ceiling priority required for a protected object with a handler to ensure that no ceiling violation will occur when that handler is invoked.
- 30/2 {AI95-00354-01} The precision of the accounting of task execution time to a `Group_Budget` is the same as that defined for execution-time clocks from the parent package.
- 31/2 {AI95-00354-01} As part of the finalization of an object of type `Group_Budget` all member tasks are removed from the group identified by that object.
- 32/3 {AI95-00354-01} {AI05-0264-1} If a task is a member of a `Group_Budget` when it terminates, then as part of the finalization of the task it is removed from the group.
- 33/2 {AI95-00354-01} For all the operations defined in this package, `Tasking_Error` is raised if the task identified by T has terminated, and `Program_Error` is raised if the value of T is `Task_Identification.Null_Task_Id`.
- 34/2 {AI95-00354-01} An exception propagated from a handler invoked when the budget of a group of tasks becomes exhausted has no effect.

Erroneous Execution

- 35/2 {AI95-00354-01} For a call of any of the subprograms defined in this package, if the task identified by T no longer exists, the execution of the program is erroneous.

Implementation Requirements

- 36/2 {AI95-00354-01} For a given `Group_Budget` object, the implementation shall perform the operations declared in this package atomically with respect to any of these operations on the same `Group_Budget` object. The replacement of a handler, by a call of `Set_Handler`, shall be performed atomically with respect to the execution of the handler.
- 36.a/2 **Reason:** This prevents various race conditions. In particular it ensures that if the budget is exhausted when `Set_Handler` is changing the handler then either the new or old handler is executed and the exhausting event is not lost.
- NOTES
- 37/2 44 {AI95-00354-01} Clearing or setting of the handler of a group budget does not change the current value of the budget. Exhaustion or loading of a budget does not change whether the handler of the group budget is set or cleared.
- 38/2 45 {AI95-00354-01} A `Group_Budget_Handler` can be associated with several `Group_Budget` objects.

Extensions to Ada 95

- 38.a/2 {AI95-00354-01} The package `Execution_Time.Group_Budgets` is new.

Inconsistencies With Ada 2005

- 38.b/3 {AI05-0169-1} A `Group_Budget` is now defined to work on a single processor. If an implementation managed to make this package work for programs running on a multiprocessor system, and a program depends on that fact, it could fail when ported to Ada 2012. We believe it is unlikely that such an implementation exists because of the difficulty of signalling other processors when the time reaches zero; in any case, depending on such an implementation is not portable.

D.14.3 Execution Time of Interrupt Handlers

{AI05-0170-1} {AI05-0299-1} This subclause describes a language-defined package to measure the execution time of interrupt handlers. 1/3

Static Semantics

{AI05-0170-1} The following language-defined library package exists: 2/3

```
with Ada.Interrupts;
package Ada.Execution_Time.Interrupts is
  function Clock (Interrupt : Ada.Interrupts.Interrupt_Id)
    return CPU_Time;
  function Supported (Interrupt : Ada.Interrupts.Interrupt_Id)
    return Boolean;
end Ada.Execution_Time.Interrupts; 3/3
```

{AI05-0170-1} The execution time or CPU time of a given interrupt `Interrupt` is defined as the time spent by the system executing interrupt handlers identified by `Interrupt`, including the time spent executing run-time or system services on its behalf. The mechanism used to measure execution time is implementation defined. Time spent executing interrupt handlers is distinct from time spent executing any task. 4/3

Discussion: The implementation-defined mechanism here is the same as that covered by the Documentation Requirements of D.14, so we don't repeat that requirement here. 4.a/3

{AI05-0170-1} For each interrupt, the execution time value is initially set to zero. 5/3

Dynamic Semantics

{AI05-0170-1} The function `Clock` returns the current cumulative execution time of the interrupt identified by `Interrupt`. If `Separate_Interrupt_Clocks_Supported` is set to `False` the function raises `Program_Error`. 6/3

{AI05-0170-1} {AI05-0264-1} The function `Supported` returns `True` if the implementation is monitoring the execution time of the interrupt identified by `Interrupt`; otherwise, it returns `False`. For any `Interrupt_Id` `Interrupt` for which `Supported(Interrupt)` returns `False`, the function `Clock(Interrupt)` will return a value equal to `Ada.Execution_Time.Time_Of(0)`. 7/3

Extensions to Ada 2005

{AI05-0170-1} The package `Execution_Time.Interrupts` is new. 7.a/3

D.15 Timing Events

{AI95-00297-01} {AI05-0299-1} This subclause describes a language-defined package to allow user-defined protected procedures to be executed at a specified time without the need for a task or a delay statement. 1/3

Static Semantics

{AI95-00297-01} The following language-defined library package exists: 2/2

```
package Ada.Real_Time.Timing_Events is
  type Timing_Event is tagged limited private;
  type Timing_Event_Handler
    is access protected procedure (Event : in out Timing_Event); 4/2
```

```

5/2      procedure Set_Handler (Event   : in out Timing_Event;
                               At_Time : in Time;
                               Handler : in Timing_Event_Handler);
procedure Set_Handler (Event   : in out Timing_Event;
                       In_Time : in Time_Span;
                       Handler : in Timing_Event_Handler);
function Current_Handler (Event : Timing_Event)
    return Timing_Event_Handler;
procedure Cancel_Handler (Event   : in out Timing_Event;
                          Cancelled : out Boolean);

6/2      function Time_Of_Event (Event : Timing_Event) return Time;

7/2      private
... -- not specified by the language
end Ada.Real_Time.Timing_Events;

```

8/2 {AI95-00297-01} The type `Timing_Event` represents a time in the future when an event is to occur. The type `Timing_Event` needs finalization (see 7.6).

9/2 {AI95-00297-01} An object of type `Timing_Event` is said to be *set* if it is associated with a nonnull value of type `Timing_Event_Handler` and *cleared* otherwise. All `Timing_Event` objects are initially cleared.

10/2 {AI95-00297-01} The type `Timing_Event_Handler` identifies a protected procedure to be executed by the implementation when the timing event occurs. Such a protected procedure is called a *handler*.

10.a/2 **Discussion:** Type `Timing_Event` is tagged. This makes it possible to share a handler between several events. In simple cases, `'Access` can be used to compare the parameter with a specific timing event object (this works because a tagged type is a by-reference type). In more complex cases, a type extension of type `Timing_Event` can be declared; a double type conversion can be used to access the extension data. For example:

```

10.b/2      type Toaster_Timing_Event is new Timing_Event with record
Slot : Natural;
end record;

10.c/2      ...

10.d/2      protected body Toaster is

10.e/2          procedure Timer (Event : in out Timing_Event) is
begin
    Pop_Up_Toast (Toaster_Timing_Event(Timing_Event'Class(Event)).Slot);
end Timer;

10.f/2      ...
end Toaster;

```

10.g/2 The extra conversion to the class-wide type is necessary to make the conversions legal. While this usage is clearly ugly, we think that the need for this sort of usage will be rare, so we can live with it. It's certainly better than having no way to associate data with an event.

Dynamic Semantics

11/3 {AI95-00297-01} {AI05-0264-1} The procedures `Set_Handler` associate the handler `Handler` with the event `Event`: if `Handler` is **null**, the event is cleared; otherwise, it is set. The first procedure `Set_Handler` sets the execution time for the event to be `At_Time`. The second procedure `Set_Handler` sets the execution time for the event to be `Real_Time.Clock + In_Time`.

12/2 {AI95-00297-01} A call of a procedure `Set_Handler` for an event that is already set replaces the handler and the time of execution; if `Handler` is not **null**, the event remains set.

13/2 {AI95-00297-01} As soon as possible after the time set for the event, the handler is executed, passing the event as parameter. The handler is only executed if the timing event is in the set state at the time of execution. The initial action of the execution of the handler is to clear the event.

13.a/2 **Reason:** The second sentence of this paragraph is because of a potential race condition. The time might expire and yet before the handler is executed, some task could call `Cancel_Handler` (or equivalently call `Set_Handler` with a **null** parameter) and thus clear the handler.

- {AI95-00297-01} If the Ceiling_Locking policy (see D.3) is in effect when a procedure Set_Handler is called, a check is made that the ceiling priority of Handler.all is Interrupt_Priority>Last. If the check fails, Program_Error is raised. 14/2
- {AI95-00297-01} {AI05-0094-1} {AI05-0264-1} If a procedure Set_Handler is called with zero or negative In_Time or with At_Time indicating a time in the past, then the handler is executed as soon as possible after the completion of the call of Set_Handler. 15/3
- Ramification:** {AI05-0094-1} The handler will still be executed. Under no circumstances is a scheduled call of a handler lost. 15.a/3
- Discussion:** {AI05-0094-1} We say “as soon as possible” so that we do not deadlock if we are executing the handler when Set_Handler is called. In that case, the current invocation of the handler must complete before the new handler can start executing. 15.b/3
- {AI95-00297-01} {AI05-0264-1} The function Current_Handler returns the handler associated with the event Event if that event is set; otherwise, it returns **null**. 16/3
- {AI95-00297-01} {AI05-0264-1} The procedure Cancel_Handler clears the event if it is set. Cancelled is assigned True if the event was set prior to it being cleared; otherwise, it is assigned False. 17/3
- {AI95-00297-01} {AI05-0264-1} The function Time_Of_Event returns the time of the event if the event is set; otherwise, it returns Real_Time.Time_First. 18/3
- {AI95-00297-01} As part of the finalization of an object of type Timing_Event, the Timing_Event is cleared. 19/2
- Implementation Note:** This is the only finalization defined by the language that has a visible effect; but an implementation may have other finalization that it needs to perform. Implementations need to ensure that the event is cleared before anything else is finalized that would prevent a set event from being triggered. 19.a/2
- {AI95-00297-01} If several timing events are set for the same time, they are executed in FIFO order of being set. 20/2
- {AI95-00297-01} An exception propagated from a handler invoked by a timing event has no effect. 21/2

Implementation Requirements

- {AI95-00297-01} For a given Timing_Event object, the implementation shall perform the operations declared in this package atomically with respect to any of these operations on the same Timing_Event object. The replacement of a handler by a call of Set_Handler shall be performed atomically with respect to the execution of the handler. 22/2
- Reason:** This prevents various race conditions. In particular it ensures that if an event occurs when Set_Handler is changing the handler then either the new or old handler is executed in response to the appropriate event. It is never possible for a new handler to be executed in response to an old event. 22.a/2

Metrics

- {AI95-00297-01} The implementation shall document the following metric: 23/2
- {AI05-0210-1} An upper bound on the lateness of the execution of a handler. That is, the maximum time between the time specified for the event and when a handler is actually invoked assuming no other handler or task is executing during this interval. 24/3
- Documentation Requirement:** The metrics for timing events. 24.a/2

Implementation Advice

- {AI95-00297-01} The protected handler procedure should be executed directly by the real-time clock interrupt mechanism. 25/2
- Implementation Advice:** For a timing event, the handler should be executed directly by the real-time clock interrupt mechanism. 25.a/2

NOTES

- 26/2 46 {AI95-00297-01} Since a call of Set_Handler is not a potentially blocking operation, it can be called from within a handler.
- 27/2 47 {AI95-00297-01} A Timing_Event_Handler can be associated with several Timing_Event objects.

Extensions to Ada 95

- 27.a/2 {AI95-00297-01} The package Real_Time.Timing_Events is new.

Wording Changes from Ada 2005

- 27.b/3 {AI05-0094-1} **Correction:** Reworded to eliminate a deadlock condition if the event time is in the past and a handler is currently executing. This is technically an inconsistency, but only if a program is depending on deadlocking; since it is impossible to imagine how that could be useful, we have not documented this as an inconsistency.
- 27.c/3 {AI05-0210-1} **Correction:** Clarified the metric for lateness of a timing event to exclude interference from other handlers and tasks. This change might change the documentation of an implementation, but not the implementation itself, so there is no inconsistency.

D.16 Multiprocessor Implementation

- 1/3 {AI05-0171-1} {AI05-0299-1} This subclause allows implementations on multiprocessor platforms to be configured.

Static Semantics

- 2/3 {AI05-0171-1} The following language-defined library package exists:
- 3/3 **package** System.Multiprocessors **is**
pragma Preelaborate(Multiprocessors);
- 4/3 **type** CPU_Range **is range** 0 .. *implementation-defined*;
 Not_A_Specific_CPU : **constant** CPU_Range := 0;
subtype CPU **is** CPU_Range **range** 1 .. CPU_Range'Last;
- 4.a.1/3 **Implementation defined:** The value of CPU_Range'Last in System.Multiprocessors.
- 5/3 **function** Number_Of_CPUs **return** CPU;
end System.Multiprocessors;
- 6/3 {AI05-0171-1} A call of Number_Of_CPUs returns the number of processors available to the program. Within a given partition, each call on Number_Of_CPUs will return the same value.
- 7/3 {AI05-0229-1} For a task type (including the anonymous type of a single_task_declaration) or subprogram, the following language-defined representation aspect may be specified:
- 8/3 CPU The aspect CPU is an expression, which shall be of type System.Multiprocessors.CPU_Range.
- 8.a/3 **Aspect Description for CPU:** Processor on which a given task should run.

Legality Rules

- 9/3 {AI05-0171-1} {AI05-0229-1} If the CPU aspect is specified for a subprogram, the expression shall be static.
- 10/3 {AI05-0229-1} The CPU aspect shall not be specified on a task interface type.

Dynamic Semantics

- 11/3 {AI05-0171-1} {AI05-0229-1} The expression specified for the CPU aspect of a task is evaluated for each task object (see 9.1). The CPU value is then associated with the task object whose task declaration specifies the aspect.
- 12/3 {AI05-0171-1} {AI05-0229-1} The CPU aspect has no effect if it is specified for a subprogram other than the main subprogram; the CPU value is not associated with any task.

{AI05-0171-1} {AI05-0229-1} The CPU value is associated with the environment task if the CPU aspect is specified for the main subprogram. If the CPU aspect is not specified for the main subprogram it is implementation defined on which processor the environment task executes. 13/3

Implementation defined: The processor on which the environment task executes in the absence of a value for the aspect CPU. 13.a.1/3

{AI05-0171-1} {AI05-0264-1} The CPU value determines the processor on which the task will activate and execute; the task is said to be assigned to that processor. If the CPU value is Not_A_Specific_CPU, then the task is not assigned to a processor. A task without a CPU aspect specified will activate and execute on the same processor as its activating task if the activating task is assigned a processor. If the CPU value is not in the range of System.Multiprocessors.CPU_Range or is greater than Number_Of_CPUs the task is defined to have failed, and it becomes a completed task (see 9.2). 14/3

Extensions to Ada 2005

{AI05-0171-1} {AI05-0229-1} The package System.Multiprocessors and the CPU aspect are new. 14.a/3

D.16.1 Multiprocessor Dispatching Domains

{AI05-0167-1} {AI05-0299-1} This subclause allows implementations on multiprocessor platforms to be partitioned into distinct dispatching domains during program startup. 1/3

Static Semantics

{AI05-0167-1} The following language-defined library package exists: 2/3

```

with Ada.Real_Time;
with Ada.Task_Identification;
package System.Multiprocessors.Dispatching_Domains is
  Dispatching_Domain_Error : exception;
  type Dispatching_Domain (<>) is limited private;
  System_Dispatching_Domain : constant Dispatching_Domain;
  function Create (First, Last : CPU) return Dispatching_Domain;
  function Get_First_CPU (Domain : Dispatching_Domain) return CPU;
  function Get_Last_CPU (Domain : Dispatching_Domain) return CPU;
  function Get_Dispatching_Domain
    (T : Ada.Task_Identification.Task_Id :=
     Ada.Task_Identification.Current_Task)
    return Dispatching_Domain;
  procedure Assign_Task
    (Domain : in out Dispatching_Domain;
     CPU : in CPU_Range := Not_A_Specific_CPU;
     T : in Ada.Task_Identification.Task_Id :=
       Ada.Task_Identification.Current_Task);
  procedure Set_CPU
    (CPU : in CPU_Range;
     T : in Ada.Task_Identification.Task_Id :=
       Ada.Task_Identification.Current_Task);
  function Get_CPU
    (T : Ada.Task_Identification.Task_Id :=
     Ada.Task_Identification.Current_Task)
    return CPU_Range;
  procedure Delay_Until_And_Set_CPU
    (Delay_Until_Time : in Ada.Real_Time.Time; CPU : in CPU_Range);
private
  ... -- not specified by the language
end System.Multiprocessors.Dispatching_Domains;

```

16/3 {AI05-0167-1} The type `Dispatching_Domain` represents a series of processors on which a task may execute. Each processor is contained within exactly one `Dispatching_Domain`. `System_Dispatching_Domain` contains the processor or processors on which the environment task executes. At program start-up all processors are contained within `System_Dispatching_Domain`.

17/3 {AI05-0167-1} For a task type (including the anonymous type of a `single_task_declaration`), the following language-defined representation aspect may be specified:

18/3 `Dispatching_Domain`

The value of aspect `Dispatching_Domain` is an expression, which shall be of type `Dispatching_Domains.Dispatching_Domain`. This aspect is the domain to which the task (or all objects of the task type) are assigned.

18.a/3 **Aspect Description for `Dispatching_Domain`:** Domain (group of processors) on which a given task should run.

Legality Rules

19/3 {AI05-0167-1} The `Dispatching_Domain` aspect shall not be specified for a task interface.

Dynamic Semantics

20/3 {AI05-0167-1} The expression specified for the `Dispatching_Domain` aspect of a task is evaluated for each task object (see 9.1). The `Dispatching_Domain` value is then associated with the task object whose task declaration specifies the aspect.

21/3 {AI05-0167-1} If a task is not explicitly assigned to any domain, it is assigned to that of the activating task. A task always executes on some CPU in its domain.

22/3 {AI05-0167-1} If both `Dispatching_Domain` and `CPU` are specified for a task, and the `CPU` value is not contained within the range of processors for the domain (and is not `Not_A_Specific_CPU`), the activation of the task is defined to have failed, and it becomes a completed task (see 9.2).

23/3 {AI05-0167-1} The function `Create` creates and returns a `Dispatching_Domain` containing all the processors in the range `First .. Last`. These processors are removed from `System_Dispatching_Domain`. A call of `Create` will raise `Dispatching_Domain_Error` if any designated processor is not currently in `System_Dispatching_Domain`, or if the system cannot support a distinct domain over the processors identified, or if a processor has a task assigned to it, or if the allocation would leave `System_Dispatching_Domain` empty. A call of `Create` will raise `Dispatching_Domain_Error` if the calling task is not the environment task, or if `Create` is called after the call to the main subprogram.

24/3 {AI05-0167-1} The function `Get_First_CPU` returns the first CPU in `Domain`; `Get_Last_CPU` returns the last one.

25/3 {AI05-0167-1} The function `Get_Dispatching_Domain` returns the `Dispatching_Domain` on which the task is assigned.

26/3 {AI05-0167-1} {AI05-0278-1} A call of the procedure `Assign_Task` assigns task T to the CPU within `Dispatching_Domain Domain`. Task T can now execute only on CPU unless CPU designates `Not_A_Specific_CPU`, in which case it can execute on any processor within `Domain`. The exception `Dispatching_Domain_Error` is propagated if T is already assigned to a `Dispatching_Domain` other than `System_Dispatching_Domain`, or if CPU is not one of the processors of `Domain` (and is not `Not_A_Specific_CPU`). A call of `Assign_Task` is a task dispatching point for task T unless T is inside of a protected action, in which case the effect on task T is delayed until its next task dispatching point. If T is the `Current_Task` the effect is immediate if T is not inside a protected action, otherwise the effect is as soon as practical. Assigning a task to `System_Dispatching_Domain` that is already assigned to that domain has no effect.

{AI05-0167-1} {AI05-0278-1} A call of procedure `Set_CPU` assigns task `T` to the CPU. Task `T` can now execute only on CPU, unless CPU designates `Not_A_Specific_CPU`, in which case it can execute on any processor within its `Dispatching_Domain`. The exception `Dispatching_Domain_Error` is propagated if CPU is not one of the processors of the `Dispatching_Domain` on which `T` is assigned (and is not `Not_A_Specific_CPU`). A call of `Set_CPU` is a task dispatching point for task `T` unless `T` is inside of a protected action, in which case the effect on task `T` is delayed until its next task dispatching point. If `T` is the `Current_Task` the effect is immediate if `T` is not inside a protected action, otherwise the effect is as soon as practical. 27/3

{AI05-0167-1} The function `Get_CPU` returns the processor assigned to task `T`, or `Not_A_Specific_CPU` if the task is not assigned to a processor. 28/3

{AI05-0167-1} A call of `Delay_Until_And_Set_CPU` delays the calling task for the designated time and then assigns the task to the specified processor when the delay expires. The exception `Dispatching_Domain_Error` is propagated if `P` is not one of the processors of the calling task's `Dispatching_Domain` (and is not `Not_A_Specific_CPU`). 29/3

Implementation Requirements

{AI05-0167-1} The implementation shall perform the operations `Assign_Task`, `Set_CPU`, `Get_CPU` and `Delay_Until_And_Set_CPU` atomically with respect to any of these operations on the same `dispatching_domain`, processor or task. 30/3

Implementation Advice

{AI05-0167-1} Each dispatching domain should have separate and disjoint ready queues. 31/3

Implementation Advice: Each dispatching domain should have separate and disjoint ready queues. 31.a/3

Documentation Requirements

{AI05-0167-1} The implementation shall document the processor(s) on which the clock interrupt is handled and hence where delay queue and ready queue manipulations occur. For any `Interrupt_Id` whose handler can execute on more than one processor the implementation shall also document this set of processors. 32/3

Documentation Requirement: The processor(s) on which the clock interrupt is handled; the processors on which each `Interrupt_Id` can be handled. 32.a/3

Implementation Permissions

{AI05-0167-1} An implementation may limit the number of dispatching domains that can be created and raise `Dispatching_Domain_Error` if an attempt is made to exceed this number. 33/3

Extensions to Ada 2005

{AI05-0167-1} {AI05-0278-1} The package `System.Multiprocessors.Dispatching_Domains` and the aspect `Dispatching_Domains` are new. 33.a/3

Annex E

(normative)

Distributed Systems

[This Annex defines facilities for supporting the implementation of distributed systems using multiple partitions working cooperatively as part of a single Ada program.] 1

Extensions to Ada 83

This Annex is new to Ada 95. 1.a

Post-Compilation Rules

A *distributed system* is an interconnection of one or more *processing nodes* (a system resource that has both computational and storage capabilities), and zero or more *storage nodes* (a system resource that has only storage capabilities, with the storage addressable by one or more processing nodes). 2

A *distributed program* comprises one or more partitions that execute independently (except when they communicate) in a distributed system. 3

The process of mapping the partitions of a program to the nodes in a distributed system is called *configuring the partitions of the program*. 4

Implementation Requirements

The implementation shall provide means for explicitly assigning library units to a partition and for the configuring and execution of a program consisting of multiple partitions on a distributed system; the means are implementation defined. 5

Implementation defined: The means for creating and executing distributed programs. 5.a

Implementation Permissions

An implementation may require that the set of processing nodes of a distributed system be homogeneous. 6

NOTES

1 The partitions comprising a program may be executed on differently configured distributed systems or on a nondistributed system without requiring recompilation. A distributed program may be partitioned differently from the same set of library units without recompilation. The resulting execution is semantically equivalent. 7

2 A distributed program retains the same type safety as the equivalent single partition program. 8

E.1 Partitions

[The partitions of a distributed program are classified as either active or passive.] 1

Post-Compilation Rules

An *active partition* is a partition as defined in 10.2. A *passive partition* is a partition that has no thread of control of its own, whose library units are all preelaborated, and whose data and subprograms are accessible to one or more active partitions. 2

Discussion: In most situations, a passive partition does not execute, and does not have a “real” environment task. Any execution involved in its elaboration and initialization occurs before it comes into existence in a distributed program (like most preelaborated entities). Likewise, there is no concrete meaning to passive partition termination. 2.a

A passive partition shall include only `library_items` that either are declared pure or are shared passive (see 10.2.1 and E.2.1). 3

4 An active partition shall be configured on a processing node. A passive partition shall be configured either on a storage node or on a processing node.

5 The configuration of the partitions of a program onto a distributed system shall be consistent with the possibility for data references or calls between the partitions implied by their semantic dependences. Any reference to data or call of a subprogram across partitions is called a *remote access*.

5.a **Discussion:** For example, an active partition that includes a unit with a semantic dependence on the declaration of another RCI package of some other active partition has to be connected to that other partition by some sort of a message passing mechanism.

5.b A passive partition that is accessible to an active partition should have its storage addressable to the processor(s) of the active partition. The processor(s) should be able to read and write from/to that storage, as well as to perform “read-modify-write” operations (in order to support entry-less protected objects).

Dynamic Semantics

6 A `library_item` is elaborated as part of the elaboration of each partition that includes it. If a normal library unit (see E.2) has state, then a separate copy of the state exists in each active partition that elaborates it. [The state evolves independently in each such partition.]

6.a **Ramification:** Normal library units cannot be included in passive partitions.

7 [An active partition *terminates* when its environment task terminates.] A partition becomes *inaccessible* if it terminates or if it is *aborted*. An active partition is aborted when its environment task is aborted. In addition, if a partition fails during its elaboration, it becomes inaccessible to other partitions. Other implementation-defined events can also result in a partition becoming inaccessible.

7.a **Implementation defined:** Any events that can result in a partition becoming inaccessible.

8/1 For a prefix `D` that denotes a library-level declaration, excepting a declaration of or within a declared-pure library unit, the following attribute is defined:

9 `D'Partition_Id`

Denotes a value of the type *universal_integer* that identifies the partition in which `D` was elaborated. If `D` denotes the declaration of a remote call interface library unit (see E.2.3) the given partition is the one where the body of `D` was elaborated.

Bounded (Run-Time) Errors

10/2 `{AI95-00226-01}` It is a bounded error for there to be cyclic elaboration dependences between the active partitions of a single distributed program. The possible effects, in each of the partitions involved, are deadlock during elaboration, or the raising of `Communication_Error` or `Program_Error`.

Implementation Permissions

11 An implementation may allow multiple active or passive partitions to be configured on a single processing node, and multiple passive partitions to be configured on a single storage node. In these cases, the scheduling policies, treatment of priorities, and management of shared resources between these partitions are implementation defined.

11.a **Implementation defined:** The scheduling policies, treatment of priorities, and management of shared resources between partitions in certain cases.

12 An implementation may allow separate copies of an active partition to be configured on different processing nodes, and to provide appropriate interactions between the copies to present a consistent state of the partition to other active partitions.

12.a **Ramification:** The language does not specify the nature of these interactions, nor the actual level of consistency preserved.

In an implementation, the partitions of a distributed program need not be loaded and elaborated all at the same time; they may be loaded and elaborated one at a time over an extended period of time. An implementation may provide facilities to abort and reload a partition during the execution of a distributed program. 13

An implementation may allow the state of some of the partitions of a distributed program to persist while other partitions of the program terminate and are later reinvoked. 14

NOTES

3 Library units are grouped into partitions after compile time, but before run time. At compile time, only the relevant library unit properties are identified using categorization pragmas. 15

4 The value returned by the `Partition_Id` attribute can be used as a parameter to implementation-provided subprograms in order to query information about the partition. 16

Wording Changes from Ada 95

{AI95-00226-01} Corrected wording so that a partition that has an elaboration problem will either deadlock or raise an exception. While an Ada 95 implementation could allow some partitions to continue to execute, they could be accessing unelaborated data, which is very bad (and erroneous in a practical sense). Therefore, this isn't listed as an inconsistency. 16.a/2

E.2 Categorization of Library Units

[Library units can be categorized according to the role they play in a distributed program. Certain restrictions are associated with each category to ensure that the semantics of a distributed program remain close to the semantics for a nondistributed program.] 1

{AI05-0243-1} A *categorization pragma* is a library unit pragma (see 10.1.5) that specifies a corresponding *categorization aspect*. A categorization aspect restricts the declarations, child units, or semantic dependences of the library unit to which it applies. A *categorized library unit* is a library unit that has a categorization aspect that is True. 2/3

{AI05-0243-1} The pragmas `Shared_Passive`, `Remote_Types`, and `Remote_Call_Interface` are categorization pragmas, and the associated aspects are categorization aspects. In addition, for the purposes of this Annex, the aspect `Pure` (see 10.2.1) is considered a categorization aspect and the pragma `Pure` is considered a categorization pragma. 3/3

{8652/0078} {AI95-00048-01} {AI05-0243-1} [A library package or generic library package is called a *shared passive* library unit if the `Shared_Passive` aspect of the unit is True. A library package or generic library package is called a *remote types* library unit if the `Remote_Types` aspect of the unit is True. A library unit is called a *remote call interface* if the `Remote_Call_Interface` aspect of the unit is True.] A *normal library unit* is one for which no categorization aspect is True. 4/3

Proof: {AI05-0243-1} {AI05-0299-1} These terms (other than “normal library unit”) are really defined in the following subclauses. 4.a/3

Ramification: {8652/0078} {AI95-00048-01} A library subprogram can be a remote call interface, but it cannot be a remote types or shared passive library unit. 4.a.1/1

{AI05-0206-1} {AI05-0243-1} {AI05-0269-1} {AI05-0299-1} [The various categories of library units and the associated restrictions are described in this and the following subclauses. The categories are related hierarchically in that the library units of one category can depend semantically only on library units of that category or an earlier one in the hierarchy, except that the body of a remote types or remote call interface library unit is unrestricted, the declaration of a remote types or remote call interface library unit may depend on preelaborated normal library units that are mentioned only in private with clauses, and all categories can depend on limited views. 5/3

6/3 {AI05-0243-1} {AI05-0269-1} The overall hierarchy (including declared pure) is as follows, with a lower-numbered category being “earlier in the hierarchy” in the sense of the previous paragraph:

- 6.1/3 1. Declared Pure
- 6.2/3 2. Shared Passive
- 6.3/3 3. Remote Types
- 6.4/3 4. Remote Call Interface
- 6.5/3 5. Normal (no restrictions)

Paragraphs 7 through 11 were deleted.

12 Declared pure and shared passive library units are preelaborated. The declaration of a remote types or remote call interface library unit is required to be preelaborable.]

Paragraph 13 was deleted.

Implementation Permissions

14 Implementations are allowed to define other categorization pragmas.

Wording Changes from Ada 95

- 14.a/2 {8652/0078} {AI95-00048-01} **Corrigendum:** Clarified that a library subprogram can be a remote call interface unit.
- 14.b/2 {8652/0079} {AI95-00208-01} **Corrigendum:** Removed the requirement that types be represented the same in all partitions, because it prevents the definition of heterogeneous distributed systems and goes much further than required.

Wording Changes from Ada 2005

- 14.c/3 {AI05-0206-1} {AI05-0299-1} We now allow private withs of preelaborated units in Remote Types and Remote Call Interface units; this is documented as an extension in the subclauses where this is defined normatively.
- 14.d/3 {AI05-0243-1} {AI05-0299-1} We have introduced categorization aspects; these are documented as extensions in the subclauses where they actually are defined.

E.2.1 Shared Passive Library Units

1 [A shared passive library unit is used for managing global data shared between active partitions. The restrictions on shared passive library units prevent the data or tasks of one active partition from being accessible to another active partition through references implicit in objects declared in the shared passive library unit.]

Language Design Principles

- 1.a The restrictions governing a shared passive library unit are designed to ensure that objects and subprograms declared in the package can be used safely from multiple active partitions, even though the active partitions live in different address spaces, and have separate run-time systems.

Syntax

2 The form of a pragma Shared_Passive is as follows:

3 **pragma** Shared_Passive[(*library_unit_name*)];

Legality Rules

4/3 {AI05-0243-1} A pragma Shared_Passive is used to specify that a library unit is a *shared passive library unit*, namely that the Shared_Passive aspect of the library unit is True. The following restrictions apply to such a library unit:

- 4.a/3 **Aspect Description for Shared_Passive:** A given package is used to represent shared memory in a distributed system.

- [it shall be preelaborable (see 10.2.1);] 5
 - Ramification:** It cannot contain library-level declarations of protected objects with entries, nor of task objects. Task objects are disallowed because passive partitions don't have any threads of control of their own, nor any run-time system of their own. Protected objects with entries are disallowed because an entry queue contains references to calling tasks, and that would require in effect a pointer from a passive partition back to a task in some active partition. 5.a
 - {AI05-0243-1} it shall depend semantically only upon declared pure or shared passive library_items; 6/3
 - Reason:** Shared passive packages cannot depend semantically upon remote types packages because the values of an access type declared in a remote types package refer to the local heap of the active partition including the remote types package. 6.a
 - Ramification:** {AI05-0243-1} We say library_item here, so that limited views are allowed; those are not library units, but they are library_item. 6.b/3
 - {8652/0080} {AI95-00003-01} it shall not contain a library-level declaration of an access type that designates a class-wide type, task type, or protected type with entry_declarations. 7/1
 - Reason:** These kinds of access types are disallowed because the object designated by an access value of such a type could contain an implicit reference back to the active partition on whose behalf the designated object was created. 7.a
- Notwithstanding the definition of accessibility given in 3.10.2, the declaration of a library unit P1 is not accessible from within the declarative region of a shared passive library unit P2, unless the shared passive library unit P2 depends semantically on P1. 8
- Discussion:** We considered a more complex rule, but dropped it. This is the simplest rule that recognizes that a shared passive package may outlive some other library package, unless it depends semantically on that package. In a nondistributed program, all library packages are presumed to have the same lifetime. 8.a
 - Implementations may define additional pragmas that force two library packages to be in the same partition, or to have the same lifetime, which would allow this rule to be relaxed in the presence of such pragmas. 8.b

Static Semantics

A shared passive library unit is preelaborated. 9

Post-Compilation Rules

A shared passive library unit shall be assigned to at most one partition within a given program. 10

Notwithstanding the rule given in 10.2, a compilation unit in a given partition does not *need* (in the sense of 10.2) the shared passive library units on which it depends semantically to be included in that same partition; they will typically reside in separate passive partitions. 11

Wording Changes from Ada 95

{8652/0080} {AI95-00003-01} **Corrigendum:** Corrected the wording to allow access types in blocks in shared passive generic packages. 11.a/2

Extensions to Ada 2005

{AI05-0243-1} Shared_Passive is now a categorization aspect, so it can be specified by an aspect_specification — although the pragma is still preferred by the Standard. 11.b/3

E.2.2 Remote Types Library Units

[A remote types library unit supports the definition of types intended for use in communication between active partitions.] 1

Language Design Principles

The restrictions governing a remote types package are similar to those for a declared pure package. However, the restrictions are relaxed deliberately to allow such a package to contain declarations that violate the stateless property of pure packages, though it is presumed that any state-dependent properties are essentially invisible outside the package. 1.a

Syntax

2 The form of a pragma Remote_Types is as follows:

3 **pragma** Remote_Types[(*library_unit_name*)];

Legality Rules

4/3 {AI05-0243-1} A pragma Remote_Types is used to specify that a library unit is a *remote types library unit*, namely that the Remote_Types aspect of the library unit is True. The following restrictions apply to the declaration of such a library unit:

4.a/3 **Aspect Description for Remote_Types:** Types in a given package may be used in remote procedure calls.

5 • [it shall be preelaborable;]

6/3 • {AI05-0206-1} {AI05-0243-1} it shall depend semantically only on declared pure library_items, shared passive library units, other remote types library units, or preelaborated normal library units that are mentioned only in private with clauses;

6.a/3 **Ramification:** {AI05-0243-1} We say declared pure library_item here, so that (all) limited views are allowed; those are not library units, but they are declared pure library_items.

7 • it shall not contain the declaration of any variable within the visible part of the library unit;

7.a **Reason:** This is essentially a “methodological” restriction. A separate copy of a remote types package is included in each partition that references it, just like a normal package. Nevertheless, a remote types package is thought of as an “essentially pure” package for defining types to be used for interpartition communication, and it could be misleading to declare visible objects when no remote data access is actually being provided.

8/2 • {AI95-00240-01} {AI95-00366-01} the full view of each type declared in the visible part of the library unit that has any available stream attributes shall support external streaming (see 13.13.2).

8.a **Reason:** This is to prevent the use of the predefined Read and Write attributes of an access type as part of the Read and Write attributes of a visible type.

8.b/2 **Ramification:** {AI95-00366-01} Types that do not have available stream attributes are excluded from this rule; that means that attributes do not need to be specified for most limited types. It is only necessary to specify attributes for nonlimited types that have a part that is of any access type, and for extensions of limited types with available stream attributes where the record_extension_part includes a subcomponent of an access type, where the access type does not have specified attributes.

9/3 {8652/0082} {AI95-00164-01} {AI05-0060-1} A named access type declared in the visible part of a remote types or remote call interface library unit is called a *remote access type*. Such a type shall be:

9.1/1 • {8652/0082} {AI95-00164-01} an access-to-subprogram type, or

9.2/3 • {8652/0082} {AI95-00164-01} {AI05-0060-1} a general access type that designates a class-wide limited private type, a class-wide limited interface type, or a class-wide private extension all of whose ancestors are either private extensions, limited interface types, or limited private types.

9.3/1 {8652/0081} {AI95-00004-01} A type that is derived from a remote access type is also a remote access type.

10 The following restrictions apply to the use of a remote access-to-subprogram type:

11/2 • {AI95-00431-01} A value of a remote access-to-subprogram type shall be converted only to or from another (subtype-conformant) remote access-to-subprogram type;

12 • The prefix of an Access attribute_reference that yields a value of a remote access-to-subprogram type shall statically denote a (subtype-conformant) remote subprogram.

13 The following restrictions apply to the use of a remote access-to-class-wide type:

14/3 • {8652/0083} {AI95-00047-01} {AI95-00240-01} {AI95-00366-01} {AI05-0060-1} {AI05-0101-1} The primitive subprograms of the corresponding specific type shall only have access parameters if they are controlling formal parameters. The primitive functions of the corresponding specific type shall only have an access result if it is a controlling access result.

Each noncontrolling formal parameter and noncontrolling result type shall support external streaming (see 13.13.2);

- {AI05-0060-1} {AI05-0215-1} {AI05-0269-1} The corresponding specific type shall not have a primitive procedure with the Synchronization aspect specified unless the `synchronization_kind` is Optional (see 9.5); 14.1/3
- A value of a remote access-to-class-wide type shall be explicitly converted only to another remote access-to-class-wide type; 15
- A value of a remote access-to-class-wide type shall be dereferenced (or implicitly converted to an anonymous access type) only as part of a dispatching call where the value designates a controlling operand of the call (see E.4, “Remote Subprogram Calls”); 16
- {AI05-0101-1} A controlling access result value for a primitive function with any controlling operands of the corresponding specific type shall either be explicitly converted to a remote access-to-class-wide type or be part of a dispatching call where the value designates a controlling operand of the call; 16.1/3
- {AI95-00366-01} The `Storage_Pool` attribute is not defined for a remote access-to-class-wide type; the expected type for an `allocator` shall not be a remote access-to-class-wide type. A remote access-to-class-wide type shall not be an actual parameter for a generic formal access type. The `Storage_Size` attribute of a remote access-to-class-wide type yields 0; it is not allowed in an `attribute_definition_clause`. 17/2
 - Reason:** {AI05-0005-1} All three of these restrictions are because there is no storage pool associated with a remote access-to-class-wide type. The `Storage_Size` is defined to be 0 so that there is no conflict with the rules for pure units. 17.a/3

NOTES

- 5 A remote types library unit need not be pure, and the types it defines may include levels of indirection implemented by using access types. User-specified Read and Write attributes (see 13.13.2) provide for sending values of such a type between active partitions, with Write marshalling the representation, and Read unmarshalling any levels of indirection. 18
- 6 {AI05-0060-1} The value of a remote access-to-class-wide limited interface can designate an object of a nonlimited type derived from the interface. 19/3
- 7 {AI05-0060-1} A remote access type may designate a class-wide synchronized, protected, or task interface type. 20/3
 - Proof:** Synchronized, protected, and task interfaces are all considered limited interfaces, see 3.9.4. 20.a/3

Incompatibilities With Ada 95

- {AI95-00240-01} {AI05-0248-1} **Amendment Correction:** The wording was changed from “user-specified” to “available” read and write attributes. (This was then further changed, see below.) This means that an access type with the attributes specified in the private part would originally have been sufficient to allow the access type to be used in a remote type, but that is no longer allowed. Similarly, the attributes of a remote type that has access components have to be specified in the visible part. These changes were made so that the rules were consistent with the rules introduced for the Corrigendum for stream attributes; moreover, legality should not depend on the contents of the private part. 20.b/3

Extensions to Ada 95

- {AI95-00366-01} {AI05-0005-1} Remote types that cannot be streamed (that is, have no available stream attributes) do not require the specification of stream attributes. This is necessary so that most extensions of `Limited_Controlled` do not need stream attributes defined (otherwise there would be a significant incompatibility, as `Limited_Controlled` would need stream attributes, and then all extensions of it also would need stream attributes). 20.c/3

Wording Changes from Ada 95

- {8652/0081} {AI95-00004-01} **Corrigendum:** Added missing wording so that a type derived from a remote access type is also a remote access type. 20.d/2
- {8652/0083} {AI95-00047-01} **Corrigendum:** Clarified that user-defined Read and Write attributes are required for the primitive subprograms corresponding to a remote access-to-class-wide type. 20.e/2
- {8652/0082} {AI95-00164-01} **Corrigendum:** Added missing wording so that a remote access type can designate an appropriate private extension. 20.f/2

- 20.g/2 {AI95-00366-01} Changed the wording to use the newly defined term *type that supports external streaming*, so that various issues with access types in pure units and implicitly declared attributes for type extensions are properly handled.
- 20.h/2 {AI95-00366-01} Defined `Storage_Size` to be 0 for remote access-to-class-wide types, rather than having it undefined. This eliminates issues with pure units requiring a defined storage size.
- 20.i/2 {AI95-00431-01} Corrected the wording so that a value of a local access-to-subprogram type cannot be converted to a remote access-to-subprogram type, as intended (and required by the ACATS).

Incompatibilities With Ada 2005

- 20.j/3 {AI05-0101-1} **Correction:** Added rules for returning of remote access-to-classwide types; this had been missed in the past. While programs that returned unstreamable types from RCI functions were legal, it is not clear what they could have done (as the results could not be marshalled). Similarly, RCI functions that return remote controlling access types could try to save those values, but it is unlikely that a compiler would know how to do that usefully. Thus, it seems unlikely that any real programs will be impacted by these changes.

Extensions to Ada 2005

- 20.k/3 {AI05-0060-1} **Correction:** Clarified that anonymous access types are never remote access types (and can be used in remote types units subject to the normal restrictions). Added wording to allow limited class-wide interfaces to be designated by remote access types.
- 20.l/3 {AI05-0206-1} Added wording to allow private withs of preelaborated normal units in the specification of a remote types unit.
- 20.m/3 {AI05-0243-1} `Remote_Types` is now a categorization aspect, so it can be specified by an `aspect_specification` — although the pragma is still preferred by the Standard.

E.2.3 Remote Call Interface Library Units

- 1 [A remote call interface library unit can be used as an interface for remote procedure calls (RPCs) (or remote function calls) between active partitions.]

Language Design Principles

- 1.a The restrictions governing a remote call interface library unit are intended to ensure that the values of the actual parameters in a remote call can be meaningfully sent between two active partitions.

Syntax

- 2 The form of a pragma `Remote_Call_Interface` is as follows:
 3 **pragma** `Remote_Call_Interface`[(*library_unit_name*)];
 4 The form of a pragma `All_Calls_Remote` is as follows:
 5 **pragma** `All_Calls_Remote`[(*library_unit_name*)];
 6 A pragma `All_Calls_Remote` is a library unit pragma.

Legality Rules

- 7/3 {8652/0078} {AI95-00048-01} {AI05-0243-1} A pragma `Remote_Call_Interface` is used to specify that a library unit is a *remote call interface (RCI)*, namely that the `Remote_Call_Interface` aspect of the library unit is `True`. A subprogram declared in the visible part of such a library unit, or declared by such a library unit, is called a *remote subprogram*.
- 7.a/3 **Aspect Description for Remote_Call_Interface:** Subprograms in a given package may be used in remote procedure calls.
- 8/3 {AI05-0206-1} {AI05-0243-1} The declaration of an RCI library unit shall be preelaborable (see 10.2.1), and shall depend semantically only upon declared pure `library_items`, shared passive library units, remote types library units, other remote call interface library units, or preelaborated normal library units that are mentioned only in private with clauses.

- Ramification:** *{AI05-0243-1}* We say declared pure library_item here, so that (all) limited views are allowed; those are not library units, but they are declared pure library_items. 8.a/3
- {8652/0078}* *{AI95-00048-01}* In addition, the following restrictions apply to an RCI library unit: 9/1
- *{8652/0078}* *{AI95-00048-01}* its visible part shall not contain the declaration of a variable; 10/1

Reason: *{8652/0078}* *{AI95-00048-01}* Remote call interface units do not provide remote data access. A shared passive package has to be used for that. 10.a/1
 - *{8652/0078}* *{AI95-00048-01}* its visible part shall not contain the declaration of a limited type; 11/1

Reason: *{AI95-00240-01}* *{AI95-00366-01}* We disallow the declaration of task and protected types, since calling an entry or a protected subprogram implicitly passes an object of a limited type (the target task or protected object). We disallow other limited types since we require that such types have available Read and Write attributes, but we certainly don't want the Read and Write attributes themselves to involve remote calls (thereby defeating their purpose of marshalling the value for remote calls). 11.a/2
 - *{8652/0078}* *{AI95-00048-01}* its visible part shall not contain a nested generic_declaration; 12/1

Reason: This is disallowed because the body of the nested generic would presumably have access to data inside the body of the RCI package, and if instantiated in a different partition, remote data access might result, which is not supported. 12.a
 - *{8652/0078}* *{AI95-00048-01}* *{AI05-0229-1}* it shall not be, nor shall its visible part contain, the declaration of a subprogram for which aspect Inline is True; 13/3
 - *{8652/0078}* *{AI95-00048-01}* *{AI95-00240-01}* *{AI95-00366-01}* *{AI05-0101-1}* it shall not be, nor shall its visible part contain, a subprogram (or access-to-subprogram) declaration whose profile has a parameter or result of a type that does not support external streaming (see 13.13.2); 14/3

Ramification: *{AI05-0101-1}* No anonymous access types support external streaming, so they are never allowed as parameters or results of RCI subprograms. 14.a/3
 - any public child of the library unit shall be a remote call interface library unit. 15

Reason: No restrictions apply to the private part of an RCI package, and since a public child can “see” the private part of its parent, such a child must itself have a Remote_Call_Interface pragma, and be assigned to the same partition (see below). 15.a

Discussion: We considered making the public child of an RCI package implicitly RCI, but it seemed better to require an explicit pragma to avoid any confusion. 15.b

Note that there is no need for a private child to be an RCI package, since it can only be seen from the body of its parent or its siblings, all of which are required to be in the same active partition. 15.c
- {AI05-0229-1}* A pragma All_Calls_Remote sets the All_Calls_Remote representation aspect of the library unit to which the pragma applies to the value True. If the All_Calls_Remote aspect of a library unit is True, the library unit shall be a remote call interface. 16/3
- Aspect Description for All_Calls_Remote:** All remote procedure calls should use the Partition Communication Subsystem, even if they are local. 16.a/3

Post-Compilation Rules

- A remote call interface library unit shall be assigned to at most one partition of a given program. A remote call interface library unit whose parent is also an RCI library unit shall be assigned only to the same partition as its parent. 17
- Implementation Note:** *{8652/0078}* *{AI95-00048-01}* The declaration of an RCI unit, with a calling-stub body, is automatically included in all active partitions with compilation units that depend on it. However the whole RCI library unit, including its (non-stub) body, will only be in one of the active partitions. 17.a/1
- Notwithstanding the rule given in 10.2, a compilation unit in a given partition that semantically depends on the declaration of an RCI library unit, *needs* (in the sense of 10.2) only the declaration of the RCI library unit, not the body, to be included in that same partition. [Therefore, the body of an RCI library unit is included only in the partition to which the RCI library unit is explicitly assigned.] 18

Implementation Requirements

- 19/3 {8652/0078} {AI95-00048-01} {AI05-0229-1} If aspect `All_Calls_Remote` is True for a given RCI library unit, then the implementation shall route any call to a subprogram of the RCI unit from outside the declarative region of the unit through the Partition Communication Subsystem (PCS); see E.5. Calls to such subprograms from within the declarative region of the unit are defined to be local and shall not go through the PCS.
- 19.a/3 **Discussion:** {8652/0078} {AI95-00048-01} {AI05-0229-1} When this aspect is False (or not used), it is presumed that most implementations will make direct calls if the call originates in the same partition as that of the RCI unit. When this aspect is True, all calls from outside the subsystem rooted at the RCI unit are treated like calls from outside the partition, ensuring that the PCS is involved in all such calls (for debugging, redundancy, etc.).
- 19.b **Reason:** There is no point to force local calls (or calls from children) to go through the PCS, since on the target system, these calls are always local, and all the units are in the same active partition.

Implementation Permissions

- 20/3 {AI05-0243-1} An implementation need not support the `Remote_Call_Interface` pragma or aspect nor the `All_Calls_Remote` pragma. [Explicit message-based communication between active partitions can be supported as an alternative to RPC.]
- 20.a **Ramification:** Of course, it is pointless to support the `All_Calls_Remote` pragma if the `Remote_Call_Interface` pragma (or some approximate equivalent) is not supported.

Incompatibilities With Ada 95

- 20.b/3 {AI95-00240-01} {AI05-0248-1} **Amendment Correction:** The wording was changed from “user-specified” to “available” read and write attributes. (This was then further changed, see below.) This means that a type with the attributes specified in the private part would originally have been allowed as a formal parameter of an RCI subprogram, but that is no longer allowed. This change was made so that the rules were consistent with the rules introduced for the Corrigendum for stream attributes; moreover, legality should not depend on the contents of the private part.

Wording Changes from Ada 95

- 20.c/2 {8652/0078} {AI95-00048-01} **Corrigendum:** Changed the wording to allow a library subprogram to be a remote call interface unit.
- 20.d/2 {AI95-00366-01} Changed the wording to use the newly defined term *type that supports external streaming*, so that various issues with access types in pure units and implicitly declared attributes for type extensions are properly handled.

Incompatibilities With Ada 2005

- 20.e/3 {AI05-0101-1} **Correction:** Added a rule to ensure that function results are streamable; this was missing in previous versions of Ada. While programs that returned unstreamable types from RCI functions were legal, it is not clear what they could have done (as the results could not be marshalled). Thus, it seems unlikely that any real programs will be impacted by this change.

Extensions to Ada 2005

- 20.f/3 {AI05-0206-1} Added wording to allow private withs of preelaborated normal units in the specification of a remote call interface unit.
- 20.g/3 {AI05-0229-1} `All_Calls_Remote` is now a representation aspect, so it can be specified by an `aspect_specification` — although the pragma is still preferred by the Standard.
- 20.h/3 {AI05-0243-1} `Remote_Call_Interface` is now a categorization aspect, so it can be specified by an `aspect_specification` — although the pragma is still preferred by the Standard.

E.3 Consistency of a Distributed System

- 1/3 {AI05-0299-1} [This subclause defines attributes and rules associated with verifying the consistency of a distributed program.]

Language Design Principles

{AI05-0248-1} The rules guarantee that remote call interface and shared passive library units are consistent among all partitions prior to the execution of a distributed program, so that the semantics of the distributed program are well defined. 1.a/3

Static Semantics

For a prefix P that statically denotes a program unit, the following attributes are defined: 2/1

P'Version Yields a value of the predefined type String that identifies the version of the compilation unit that contains the declaration of the program unit. 3

P'Body_Version Yields a value of the predefined type String that identifies the version of the compilation unit that contains the body (but not any subunits) of the program unit. 4

{8652/0084} {AI95-00104-01} The *version* of a compilation unit changes whenever the compilation unit changes in a semantically significant way. This International Standard does not define the exact meaning of "semantically significant". It is unspecified whether there are other events (such as recompilation) that result in the version of a compilation unit changing. 5/1

This paragraph was deleted. 5.a/1

{8652/0084} {AI95-00104-01} If P is not a library unit, and P has no completion, then P'Body_Version returns the Body_Version of the innermost program unit enclosing the declaration of P. If P is a library unit, and P has no completion, then P'Body_Version returns a value that is different from Body_Version of any version of P that has a completion. 5.1/1

Bounded (Run-Time) Errors

In a distributed program, a library unit is *consistent* if the same version of its declaration is used throughout. It is a bounded error to elaborate a partition of a distributed program that contains a compilation unit that depends on a different version of the declaration of a shared passive or RCI library unit than that included in the partition to which the shared passive or RCI library unit was assigned. As a result of this error, Program_Error can be raised in one or both partitions during elaboration; in any case, the partitions become inaccessible to one another. 6

Ramification: Because a version changes if anything on which it depends undergoes a version change, requiring consistency for shared passive and remote call interface library units is sufficient to ensure consistency for the declared pure and remote types library units that define the types used for the objects and parameters through which interpartition communication takes place. 6.a

Note that we do not require matching Body_Versions; it is irrelevant for shared passive and remote call interface packages, since only one copy of their body exists in a distributed program (in the absence of implicit replication), and we allow the bodies to differ for declared pure and remote types packages from partition to partition, presuming that the differences are due to required error corrections that took place during the execution of a long-running distributed program. The Body_Version attribute provides a means for performing stricter consistency checks. 6.b

Wording Changes from Ada 95

{8652/0084} {AI95-00104-01} **Corrigendum:** Clarified the meaning of 'Version and 'Body_Version. 6.c/2

E.4 Remote Subprogram Calls

A *remote subprogram call* is a subprogram call that invokes the execution of a subprogram in another partition. The partition that originates the remote subprogram call is the *calling partition*, and the partition that executes the corresponding subprogram body is the *called partition*. Some remote procedure calls are allowed to return prior to the completion of subprogram execution. These are called *asynchronous remote procedure calls*. 1

2 There are three different ways of performing a remote subprogram call:

- 3 • As a direct call on a (remote) subprogram explicitly declared in a remote call interface;
- 4 • As an indirect call through a value of a remote access-to-subprogram type;
- 5 • As a dispatching call with a controlling operand designated by a value of a remote access-to-class-wide type.

6 The first way of calling corresponds to a *static* binding between the calling and the called partition. The latter two ways correspond to a *dynamic* binding between the calling and the called partition.

7/3 {AI05-0101-1} Remote types library units (see E.2.2) and remote call interface library units (see E.2.3) define the remote subprograms or remote access types used for remote subprogram calls.

Language Design Principles

7.a Remote subprogram calls are standardized since the RPC paradigm is widely-used, and establishing an interface to it in the annex will increase the portability and reusability of distributed programs.

Legality Rules

8 In a dispatching call with two or more controlling operands, if one controlling operand is designated by a value of a remote access-to-class-wide type, then all shall be.

Dynamic Semantics

9 For the execution of a remote subprogram call, subprogram parameters (and later the results, if any) are passed using a stream-oriented representation (see 13.13.1) [which is suitable for transmission between partitions]. This action is called *marshalling*. *Unmarshalling* is the reverse action of reconstructing the parameters or results from the stream-oriented representation. [Marshalling is performed initially as part of the remote subprogram call in the calling partition; unmarshalling is done in the called partition. After the remote subprogram completes, marshalling is performed in the called partition, and finally unmarshalling is done in the calling partition.]

10 A *calling stub* is the sequence of code that replaces the subprogram body of a remotely called subprogram in the calling partition. A *receiving stub* is the sequence of code (the “wrapper”) that receives a remote subprogram call on the called partition and invokes the appropriate subprogram body.

10.a **Discussion:** The use of the term *stub* in this annex should not be confused with `body_stub` as defined in 10.1.3. The term *stub* is used here because it is a commonly understood term when talking about the RPC paradigm.

11 Remote subprogram calls are executed at most once, that is, if the subprogram call returns normally, then the called subprogram's body was executed exactly once.

12 The task executing a remote subprogram call blocks until the subprogram in the called partition returns, unless the call is asynchronous. For an asynchronous remote procedure call, the calling task can become ready before the procedure in the called partition returns.

13 If a construct containing a remote call is aborted, the remote subprogram call is *cancelled*. Whether the execution of the remote subprogram is immediately aborted as a result of the cancellation is implementation defined.

13.a **Implementation defined:** Whether the execution of the remote subprogram is immediately aborted as a result of cancellation.

14 If a remote subprogram call is received by a called partition before the partition has completed its elaboration, the call is kept pending until the called partition completes its elaboration (unless the call is cancelled by the calling partition prior to that).

If an exception is propagated by a remotely called subprogram, and the call is not an asynchronous call, the corresponding exception is reraised at the point of the remote subprogram call. For an asynchronous call, if the remote procedure call returns prior to the completion of the remotely called subprogram, any exception is lost. 15

The exception `Communication_Error` (see E.5) is raised if a remote call cannot be completed due to difficulties in communicating with the called partition. 16

All forms of remote subprogram calls are potentially blocking operations (see 9.5.1). 17

Reason: Asynchronous remote procedure calls are potentially blocking since the implementation may require waiting for the availability of shared resources to initiate the remote call. 17.a

{8652/0085} {AI95-00215-01} In a remote subprogram call with a formal parameter of a class-wide type, a check is made that the tag of the actual parameter identifies a tagged type declared in a declared-pure or shared passive library unit, or in the visible part of a remote types or remote call interface library unit. `Program_Error` is raised if this check fails. In a remote function call which returns a class-wide type, the same check is made on the function result. 18/1

Discussion: {8652/0085} {AI95-00215-01} This check makes certain that the specific type passed or returned in an RPC satisfies the rules for a "communicable" type. Normally this is guaranteed by the compile-time restrictions on remote call interfaces. However, with class-wide types, it is possible to pass an object whose tag identifies a type declared outside the "safe" packages. 18.a/1

This is considered an `accessibility_check` since only the types declared in "safe" packages are considered truly "global" (cross-partition). Other types are local to a single partition. This is analogous to the "accessibility" of global vs. local declarations in a single-partition program. 18.b

This rule replaces a rule from an early version of Ada 9X which was given in the subclause on Remote Types Library Units (now E.2.2, "Remote Types Library Units"). That rule tried to prevent "bad" types from being sent by arranging for their tags to mismatch between partitions. However, that interfered with other uses of tags. The new rule allows tags to agree in all partitions, even for those types which are not "safe" to pass in an RPC. 18.c

In a dispatching call with two or more controlling operands that are designated by values of a remote access-to-class-wide type, a check is made [(in addition to the normal `Tag_Check` — see 11.5)] that all the remote access-to-class-wide values originated from `Access attribute_references` that were evaluated by tasks of the same active partition. `Constraint_Error` is raised if this check fails. 19

Implementation Note: When a remote access-to-class-wide value is created by an `Access attribute_reference`, the identity of the active partition that evaluated the `attribute_reference` should be recorded in the representation of the remote access value. 19.a

Implementation Requirements

The implementation of remote subprogram calls shall conform to the PCS interface as defined by the specification of the language-defined package `System.RPC` (see E.5). The calling stub shall use the `Do_RPC` procedure unless the remote procedure call is asynchronous in which case `Do_APC` shall be used. On the receiving side, the corresponding receiving stub shall be invoked by the RPC-receiver. 20

Implementation Note: One possible implementation model is as follows: 20.a

The code for calls to subprograms declared in an RCI package is generated normally, that is, the call-site is the same as for a local subprogram call. The code for the remotely callable subprogram bodies is also generated normally. Subprogram's prologue and epilogue are the same as for a local call. 20.b

When compiling the specification of an RCI package, the compiler generates calling stubs for each visible subprogram. Similarly, when compiling the body of an RCI package, the compiler generates receiving stubs for each visible subprogram together with the appropriate tables to allow the RPC-receiver to locate the correct receiving stub. 20.c

For the statically bound remote calls, the identity of the remote partition is statically determined (it is resolved at configuration/link time). 20.d

The calling stub operates as follows: 20.e

- 20.f
- It allocates (or reuses) a stream of `Params_Stream_Type` of `Initial_Size`, and initializes it by repeatedly calling `Write` operations, first to identify which remote subprogram in the receiving partition is being called, and then to pass the incoming value of each of the **in** and **in out** parameters of the call.
- 20.g/3
- *{AI05-0229-1}* It allocates (or reuses) a stream for the `Result`, unless an aspect `Asynchronous` is specified as `True` for the procedure.
- 20.h/3
- *{AI05-0229-1}* It calls `Do_RPC` unless an aspect `Asynchronous` is specified as `True` for the procedure in which case it calls `Do_APC`. An access value designating the message stream allocated and initialized above is passed as the `Params` parameter. An access value designating the `Result` stream is passed as the `Result` parameter.
- 20.i/3
- *{AI05-0229-1}* If the aspect `Asynchronous` is not specified for the procedure, `Do_RPC` blocks until a reply message arrives, and then returns to the calling stub. The stub returns after extracting from the `Result` stream, using `Read` operations, the **in out** and **out** parameters or the function result. If the reply message indicates that the execution of the remote subprogram propagated an exception, the exception is propagated from `Do_RPC` to the calling stub, and thence to the point of the original remote subprogram call. If `Do_RPC` detects that communication with the remote partition has failed, it propagates `Communication_Error`.
- 20.j
- On the receiving side, the RPC-receiver procedure operates as follows:
- 20.k
- It is called from the PCS when a remote-subprogram-call message is received. The call originates in some remote call receiver task executed and managed in the context of the PCS.
- 20.l
- It extracts information from the stream to identify the appropriate receiving stub.
- 20.m
- The receiving stub extracts the **in** and **in out** parameters using `Read` from the stream designated by the `Params` parameter.
- 20.n
- The receiving stub calls the actual subprogram body and, upon completion of the subprogram, uses `Write` to insert the results into the stream pointed to by the `Result` parameter. The receiving stub returns to the RPC-receiver procedure which in turn returns to the PCS. If the actual subprogram body propagates an exception, it is propagated by the RPC-receiver to the PCS, which handles the exception, and indicates in the reply message that the execution of the subprogram body propagated an exception. The exception occurrence can be represented in the reply message using the `Write` attribute of `Ada.Exceptions.Exception_Occurrence`.
- 20.o
- For remote access-to-subprogram types:
- 20.p
- A value of a remote access-to-subprogram type can be represented by the following components: a reference to the remote partition, an index to the package containing the remote subprogram, and an index to the subprogram within the package. The values of these components are determined at run time when the remote access value is created. These three components serve the same purpose when calling `Do_APC/RPC`, as in the statically bound remote calls; the only difference is that they are evaluated dynamically.
- 20.q
- For remote access-to-class-wide types:
- 20.r
- For each remote access-to-class-wide type, a calling stub is generated for each dispatching operation of the designated type. In addition, receiving stubs are generated to perform the remote dispatching operations in the called partition. The appropriate `subprogram_body` is determined as for a local dispatching call once the receiving stub has been reached.
- 20.s
- A value of a remote access-to-class-wide type can be represented with the following components: a reference to the remote partition, an index to a table (created one per each such access type) containing addresses of all the dispatching operations of the designated type, and an access value designating the actual remote object.
- 20.t
- Alternatively, a remote access-to-class-wide value can be represented as a normal access value, pointing to a "stub" object which in turn contains the information mentioned above. A call on any dispatching operation of such a stub object does the remote call, if necessary, using the information in the stub object to locate the target partition, etc. This approach has the advantage that less special-casing is required in the compiler. All access values can remain just a simple address.
- 20.u
- For a call to `Do_RPC` or `Do_APC`: The partition ID of all controlling operands are checked for equality (a `Constraint_Error` is raised if this check fails). The partition ID value is used for the `Partition` parameter. An index into the *tagged-type-descriptor* is created. This index points to the receiving stub of the class-wide operation. This index and the index to the table (described above) are written to the stream. Then, the actual parameters are marshalled into the message stream. For a controlling operand, only the access value designating the remote object is required (the other two components are already present in the other parameters).
- 20.v
- On the called partition (after the RPC-receiver has transferred control to the appropriate receiving stub) the parameters are first unmarshalled. Then, the tags of the controlling operands (obtained by dereferencing the pointer to the object) are checked for equality. If the check fails `Constraint_Error` is raised and propagated back to the calling partition, unless it is a result of an asynchronous call. Finally, a dispatching call to the specific subprogram (based on the controlling object's tag) is made. Note that since this subprogram is not in an RCI package, no specific stub is generated for it, it is called normally from the *dispatching stub*.

{8652/0086} {AI95-00159-01} With respect to shared variables in shared passive library units, the execution of the corresponding subprogram body of a synchronous remote procedure call is considered to be part of the execution of the calling task. The execution of the corresponding subprogram body of an asynchronous remote procedure call proceeds in parallel with the calling task and does not signal the next action of the calling task (see 9.10). 20.1/1

NOTES

8 A given active partition can both make and receive remote subprogram calls. Thus, an active partition can act as both a client and a server. 21

9 If a given exception is propagated by a remote subprogram call, but the exception does not exist in the calling partition, the exception can be handled by an **others** choice or be propagated to and handled by a third partition. 22

Discussion: This situation can happen in a case of dynamically nested remote subprogram calls, where an intermediate call executes in a partition that does not include the library unit that defines the exception. 22.a

Wording Changes from Ada 95

{8652/0086} {AI95-00159-01} **Corrigendum:** Added rules so that tasks can safely access shared passive objects. 22.b/2

{8652/0085} {AI95-00215-01} **Corrigendum:** Clarified that the check on class-wide types also applies to values returned from remote subprogram call functions. 22.c/2

Wording Changes from Ada 2005

{AI05-0101-1} **Correction:** Corrected the text to note that remote access types can be defined in remote types units. 22.d/3

E.4.1 Asynchronous Remote Calls

{AI05-0229-1} [This subclause introduces the aspect Asynchronous which can be specified to allow a remote subprogram call to return prior to completion of the execution of the corresponding remote subprogram body.] 1/3

Paragraphs 2 through 7 were deleted.

Static Semantics

{AI05-0229-1} For a remote procedure, the following language-defined representation aspect may be specified: 8/3

Asynchronous 8.1/3

The type of aspect Asynchronous is Boolean. If directly specified, the `aspect_definition` shall be a static expression. If not specified, the aspect is False.

Aspect Description for Asynchronous: Remote procedure calls are asynchronous; the caller continues without waiting for the call to return. 8.a/3

{AI05-0229-1} For a remote access type, the following language-defined representation aspect may be specified: 8.2/3

Asynchronous 8.3/3

The type of aspect Asynchronous is Boolean. If directly specified, the `aspect_definition` shall be a static expression. If not specified (including by inheritance), the aspect is False.

Legality Rules

{AI05-0229-1} If aspect Asynchronous is specified for a remote procedure, the formal parameters of the procedure shall all be of mode **in**. 8.4/3

{AI05-0229-1} If aspect Asynchronous is specified for a remote access type, the type shall be a remote access-to-class-wide type, or the type shall be a remote access-to-procedure type with the formal parameters of the designated profile of the type all of mode **in**. 8.5/3

Dynamic Semantics

- 9/3 {AI05-0229-1} A remote call is *asynchronous* if it is a call to a procedure, or a call through a value of an access-to-procedure type, for which aspect Asynchronous is True. In addition, if aspect Asynchronous is True for a remote access-to-class-wide type, then a dispatching call on a procedure with a controlling operand designated by a value of the type is asynchronous if the formal parameters of the procedure are all of mode **in**.

Implementation Requirements

- 10 Asynchronous remote procedure calls shall be implemented such that the corresponding body executes at most once as a result of the call.
- 10.a **To be honest:** It is not clear that this rule can be tested or even defined formally.

Extensions to Ada 2005

- 10.b/3 {AI05-0229-1} Aspect Asynchronous is new; pragma Asynchronous is now obsolescent.

E.4.2 Example of Use of a Remote Access-to-Class-Wide Type*Examples*

- 1 *Example of using a remote access-to-class-wide type to achieve dynamic binding across active partitions:*

```

2  package Tapes is
    pragma Pure(Tapes);
    type Tape is abstract tagged limited private;
    -- Primitive dispatching operations where
    -- Tape is controlling operand
    procedure Copy (From, To : access Tape; Num_Recs : in Natural) is abstract;
    procedure Rewind (T : access Tape) is abstract;
    -- More operations
  private
    type Tape is ...
  end Tapes;
3  with Tapes;
  package Name_Server is
    pragma Remote_Call_Interface;
    -- Dynamic binding to remote operations is achieved
    -- using the access-to-limited-class-wide type Tape_Ptr
    type Tape_Ptr is access all Tapes.Tape'Class;
    -- The following statically bound remote operations
    -- allow for a name-server capability in this example
    function Find (Name : String) return Tape_Ptr;
    procedure Register (Name : in String; T : in Tape_Ptr);
    procedure Remove (T : in Tape_Ptr);
    -- More operations
  end Name_Server;
4  package Tape_Driver is
    -- Declarations are not shown, they are irrelevant here
  end Tape_Driver;

```

```

with Tapes, Name_Server;
package body Tape_Driver is
  type New_Tape is new Tapes.Tape with ...
  procedure Copy
    (From, To : access New_Tape; Num_Recs: in Natural) is
  begin
    . . .
  end Copy;
  procedure Rewind (T : access New_Tape) is
  begin
    . . .
  end Rewind;
  -- Objects remotely accessible through use
  -- of Name_Server operations
  Tape1, Tape2 : aliased New_Tape;
begin
  Name_Server.Register ("NINE-TRACK", Tape1'Access);
  Name_Server.Register ("SEVEN-TRACK", Tape2'Access);
end Tape_Driver;

with Tapes, Name_Server;
-- Tape_Driver is not needed and thus not mentioned in the with_clause
procedure Tape_Client is
  T1, T2 : Name_Server.Tape_Ptr;
begin
  T1 := Name_Server.Find ("NINE-TRACK");
  T2 := Name_Server.Find ("SEVEN-TRACK");
  Tapes.Rewind (T1);
  Tapes.Rewind (T2);
  Tapes.Copy (T1, T2, 3);
end Tape_Client;

```

Notes on the example:

Discussion: The example does not show the case where tapes are removed from or added to the system. In the former case, an appropriate exception needs to be defined to instruct the client to use another tape. In the latter, the Name_Server should have a query function visible to the clients to inform them about the availability of the tapes in the system.

This paragraph was deleted.

- The package Tapes provides the necessary declarations of the type and its primitive operations.
- Name_Server is a remote call interface package and is elaborated in a separate active partition to provide the necessary naming services (such as Register and Find) to the entire distributed program through remote subprogram calls.
- Tape_Driver is a normal package that is elaborated in a partition configured on the processing node that is connected to the tape device(s). The abstract operations are overridden to support the locally declared tape devices (Tape1, Tape2). The package is not visible to its clients, but it exports the tape devices (as remote objects) through the services of the Name_Server. This allows for tape devices to be dynamically added, removed or replaced without requiring the modification of the clients' code.
- The Tape_Client procedure references only declarations in the Tapes and Name_Server packages. Before using a tape for the first time, it needs to query the Name_Server for a system-wide identity for that tape. From then on, it can use that identity to access the tape device.
- Values of remote access type Tape_Ptr include the necessary information to complete the remote dispatching operations that result from dereferencing the controlling operands T1 and T2.

E.5 Partition Communication Subsystem

1/2 {AI95-00273-01} [The *Partition Communication Subsystem* (PCS) provides facilities for supporting communication between the active partitions of a distributed program. The package System.RPC is a language-defined interface to the PCS.]

1.a **Reason:** The prefix RPC is used rather than RSC because the term remote procedure call and its acronym are more familiar.

Static Semantics

2 The following language-defined library package exists:

```

3  with Ada.Streams; -- see 13.13.1
  package System.RPC is
4      type Partition_Id is range 0 .. implementation-defined;
5      Communication_Error : exception;
6      type Params_Stream_Type (
          Initial_Size : Ada.Streams.Stream_Element_Count) is new
          Ada.Streams.Root_Stream_Type with private;
7      procedure Read(
          Stream : in out Params_Stream_Type;
          Item : out Ada.Streams.Stream_Element_Array;
          Last : out Ada.Streams.Stream_Element_Offset);
8      procedure Write(
          Stream : in out Params_Stream_Type;
          Item : in Ada.Streams.Stream_Element_Array);
9      -- Synchronous call
      procedure Do_RPC(
          Partition : in Partition_Id;
          Params : access Params_Stream_Type;
          Result : access Params_Stream_Type);
10     -- Asynchronous call
      procedure Do_APC(
          Partition : in Partition_Id;
          Params : access Params_Stream_Type);
11     -- The handler for incoming RPCs
      type RPC_Receiver is access procedure(
          Params : access Params_Stream_Type;
          Result : access Params_Stream_Type);
12     procedure Establish_RPC_Receiver(
          Partition : in Partition_Id;
          Receiver : in RPC_Receiver);
13     private
        ... -- not specified by the language
    end System.RPC;
```

14 A value of the type Partition_Id is used to identify a partition.

14.a/2 **Implementation defined:** The range of type System.RPC.Partition_Id.

15 An object of the type Params_Stream_Type is used for identifying the particular remote subprogram that is being called, as well as marshalling and unmarshalling the parameters or result of a remote subprogram call, as part of sending them between partitions.

16 [The Read and Write procedures override the corresponding abstract operations for the type Params_Stream_Type.]

Dynamic Semantics

The Do_RPC and Do_APC procedures send a message to the active partition identified by the Partition parameter. 17

Implementation Note: It is assumed that the RPC interface is above the message-passing layer of the network protocol stack and is implemented in terms of it. 17.a

After sending the message, Do_RPC blocks the calling task until a reply message comes back from the called partition or some error is detected by the underlying communication system in which case Communication_Error is raised at the point of the call to Do_RPC. 18

Reason: Only one exception is defined in System.RPC, although many sources of errors might exist. This is so because it is not always possible to distinguish among these errors. In particular, it is often impossible to tell the difference between a failing communication link and a failing processing node. Additional information might be associated with a particular Exception_Occurrence for a Communication_Error. 18.a

Do_APC operates in the same way as Do_RPC except that it is allowed to return immediately after sending the message. 19

Upon normal return, the stream designated by the Result parameter of Do_RPC contains the reply message. 20

The procedure System.RPC.Establish_RPC_Receiver is called once, immediately after elaborating the library units of an active partition (that is, right after the *elaboration of the partition*) if the partition includes an RCI library unit, but prior to invoking the main subprogram, if any. The Partition parameter is the Partition_Id of the active partition being elaborated. The Receiver parameter designates an implementation-provided procedure called the *RPC-receiver* which will handle all RPCs received by the partition from the PCS. Establish_RPC_Receiver saves a reference to the RPC-receiver; when a message is received at the called partition, the RPC-receiver is called with the Params stream containing the message. When the RPC-receiver returns, the contents of the stream designated by Result is placed in a message and sent back to the calling partition. 21

Implementation Note: It is defined by the PCS implementation whether one or more threads of control should be available to process incoming messages and to wait for their completion. 21.a

Implementation Note: At link-time, the linker provides the RPC-receiver and the necessary tables to support it. A call on Establish_RPC_Receiver is inserted just before the call on the main subprogram. 21.b

Reason: The interface between the PCS (the System.RPC package) and the RPC-receiver is defined to be dynamic in order to allow the elaboration sequence to notify the PCS that all packages have been elaborated and that it is safe to call the receiving stubs. It is not guaranteed that the PCS units will be the last to be elaborated, so some other indication that elaboration is complete is needed. 21.c

If a call on Do_RPC is aborted, a cancellation message is sent to the called partition, to request that the execution of the remotely called subprogram be aborted. 22

To be honest: The full effects of this message are dependent on the implementation of the PCS. 22.a

The subprograms declared in System.RPC are potentially blocking operations. 23

Implementation Requirements

The implementation of the RPC-receiver shall be reentrant[, thereby allowing concurrent calls on it from the PCS to service concurrent remote subprogram calls into the partition]. 24

Reason: There seems no reason to allow the implementation of RPC-receiver to be nonreentrant, even though we don't require that every implementation of the PCS actually perform concurrent calls on the RPC-receiver. 24.a

{8652/0087} {A195-00082-01} An implementation shall not restrict the replacement of the body of System.RPC. An implementation shall not restrict children of System.RPC. [The related implementation permissions in the introduction to Annex A do not apply.] 24.1/1

24.a.1/1 **Reason:** The point of System.RPC is to let the user tailor the communications mechanism without requiring changes to or other cooperation from the compiler. However, implementations can restrict the replacement of language-defined units. This requirement overrides that permission for System.RPC.

24.2/1 {8652/0087} {AI95-00082-01} If the implementation of System.RPC is provided by the user, an implementation shall support remote subprogram calls as specified.

24.b/2 **Discussion:** {AI95-00273-01} If the implementation takes advantage of the implementation permission to use a different specification for System.RPC, it still needs to use it for remote subprogram calls, and allow the user to replace the body of System.RPC. It just isn't guaranteed to be portable to do so in Ada 2005 - an advantage which was more theoretical than real anyway.

Documentation Requirements

25 The implementation of the PCS shall document whether the RPC-receiver is invoked from concurrent tasks. If there is an upper limit on the number of such tasks, this limit shall be documented as well, together with the mechanisms to configure it (if this is supported).

25.a/2 *This paragraph was deleted.*

25.a.1/2 **Documentation Requirement:** Whether the RPC-receiver is invoked from concurrent tasks, and if so, the number of such tasks.

Implementation Permissions

26 The PCS is allowed to contain implementation-defined interfaces for explicit message passing, broadcasting, etc. Similarly, it is allowed to provide additional interfaces to query the state of some remote partition (given its partition ID) or of the PCS itself, to set timeouts and retry parameters, to get more detailed error status, etc. These additional interfaces should be provided in child packages of System.RPC.

26.a **Implementation defined:** Implementation-defined interfaces in the PCS.

27 A body for the package System.RPC need not be supplied by the implementation.

27.a **Reason:** It is presumed that a body for the package System.RPC might be extremely environment specific. Therefore, we do not require that a body be provided by the (compiler) implementation. The user will have to write a body, or acquire one, appropriate for the target environment.

27.1/3 {AI95-00273-01} {AI05-0299-1} An alternative declaration is allowed for package System.RPC as long as it provides a set of operations that is substantially equivalent to the specification defined in this subclause.

27.b/2 **Reason:** Experience has proved that the definition of System.RPC given here is inadequate for interfacing to existing distribution mechanisms (such as CORBA), especially on heterogeneous systems. Rather than mandate a change in the mechanism (which would break existing systems), require implementations to support multiple mechanisms (which is impractical), or prevent the use of Annex E facilities with existing systems (which would be silly), we simply make this facility optional.

27.c/2 One of the purposes behind System.RPC was that knowledgeable users, rather than compiler vendors, could create this package tailored to their networks. Experience has shown that users get their RPC from vendors anyway; users have not taken advantage of the flexibility provided by this defined interface. Moreover, one could compare this defined interface to requiring Ada compilers to use a defined interface to implement tasking. No one thinks that the latter is a good idea, why should anyone believe that the former is?

27.d/3 {AI05-0299-1} Therefore, this subclause is made optional. We considered deleting the subclause outright, but we still require that users may replace the package (whatever its interface). Also, it still provides a useful guide to the implementation of this feature.

Implementation Advice

28 Whenever possible, the PCS on the called partition should allow for multiple tasks to call the RPC-receiver with different messages and should allow them to block until the corresponding subprogram body returns.

28.a/2 **Implementation Advice:** The PCS should allow for multiple tasks to call the RPC-receiver.

The Write operation on a stream of type `Params_Stream_Type` should raise `Storage_Error` if it runs out of space trying to write the `Item` into the stream. 29

Implementation Advice: The `System.RPC.Write` operation should raise `Storage_Error` if it runs out of space when writing an item. 29.a.1/2

Implementation Note: An implementation could also dynamically allocate more space as needed, only propagating `Storage_Error` if the `allocator` it calls raises `Storage_Error`. This storage could be managed through a controlled component of the stream object, to ensure that it is reclaimed when the stream object is finalized. 29.a

NOTES

10 The package `System.RPC` is not designed for direct calls by user programs. It is instead designed for use in the implementation of remote subprograms calls, being called by the calling stubs generated for a remote call interface library unit to initiate a remote call, and in turn calling back to an RPC-receiver that dispatches to the receiving stubs generated for the body of a remote call interface, to handle a remote call received from elsewhere. 30

Incompatibilities With Ada 95

{*AI95-00273-01*} The specification of `System.RPC` can now be tailored for an implementation. If a program replaces the body of `System.RPC` with a user-defined body, it might not compile in a given implementation of Ada 2005 (if the specification of `System.RPC` has been changed). 30.a/2

Wording Changes from Ada 95

{*8652/0087*} {*AI95-00082-01*} **Corrigendum:** Clarified that the user can replace `System.RPC`. 30.b/2

Annex F

(normative)

Information Systems

This Annex provides a set of facilities relevant to Information Systems programming. These fall into several categories: 1

- an attribute definition clause specifying `Machine_Radix` for a decimal subtype; 2
- the package `Decimal`, which declares a set of constants defining the implementation's capacity for decimal types, and a generic procedure for decimal division; and 3
- `{AI95-00285-01}` the child packages `Text_IO Editing`, `Wide_Text_IO Editing`, and `Wide_Wide_Text_IO Editing`, which support formatted and localized output of decimal data, based on “picture String” values. 4/2

`{AI95-00434-01}` See also: 3.5.9, “Fixed Point Types”; 3.5.10, “Operations of Fixed Point Types”; 4.6, “Type Conversions”; 13.3, “Operational and Representation Attributes”; A.10.9, “Input-Output for Real Types”; B.3, “Interfacing with C and C++”; B.4, “Interfacing with COBOL”; Annex G, “Numerics”. 5/2

The character and string handling packages in Annex A, “Predefined Language Environment” are also relevant for Information Systems. 6

Implementation Advice

`{AI05-0229-1}` If COBOL (respectively, C) is widely supported in the target environment, implementations supporting the Information Systems Annex should provide the child package `Interfaces.COBOL` (respectively, `Interfaces.C`) specified in Annex B and should support a *convention_identifier* of COBOL (respectively, C) for the Convention aspect (see Annex B), thus allowing Ada programs to interface with programs written in that language. 7/3

Implementation Advice: If COBOL (respectively, C) is supported in the target environment, then interfacing to COBOL (respectively, C) should be supported as specified in Annex B. 7.a/2

Extensions to Ada 83

This Annex is new to Ada 95. 7.b

Wording Changes from Ada 95

`{AI95-00285-01}` Added a mention of `Wide_Wide_Text_IO Editing`, part of the support for 32-bit characters. 7.c/2

F.1 `Machine_Radix` Attribute Definition Clause

Static Semantics

`Machine_Radix` may be specified for a decimal first subtype (see 3.5.9) via an *attribute_definition_clause*; the expression of such a clause shall be static, and its value shall be 2 or 10. A value of 2 implies a binary base range; a value of 10 implies a decimal base range. 1

Ramification: In the absence of a `Machine_Radix` clause, the choice of 2 versus 10 for `S'Machine_Radix` is not specified. 1.a

Aspect Description for `Machine_Radix`: Radix (2 or 10) that is used to represent a decimal fixed point type. 1.b/3

Implementation Advice

Packed decimal should be used as the internal representation for objects of subtype S when `S'Machine_Radix = 10`. 2

- 2.a/2 **Implementation Advice:** Packed decimal should be used as the internal representation for objects of subtype *S* when *S*'Machine_Radix = 10.
- 2.b/3 **Discussion:** {AI05-0229-1} The intent of a decimal Machine_Radix attribute definition clause is to allow the programmer to declare an Ada decimal data object whose representation matches a particular COBOL implementation's representation of packed decimal items. The Ada object may then be passed to an interfaced COBOL program that takes a packed decimal data item as a parameter, assuming that convention COBOL has been specified for the Ada object's type with an aspect Convention.
- 2.c Additionally, the Ada compiler may choose to generate arithmetic instructions that exploit the packed decimal representation.

Examples

3 *Example of Machine_Radix attribute definition clause:*

```
4      type Money is delta 0.01 digits 15;
      for Money'Machine_Radix use 10;
```

F.2 The Package Decimal

Static Semantics

1 The library package Decimal has the following declaration:

```
2      package Ada.Decimal is
      pragma Pure(Decimal);
3      Max_Scale : constant := implementation-defined;
      Min_Scale : constant := implementation-defined;
4      Min_Delta : constant := 10.0**(-Max_Scale);
      Max_Delta : constant := 10.0**(-Min_Scale);
5      Max_Decimal_Digits : constant := implementation-defined;
6/3    {AI05-0229-1} generic
      type Dividend_Type is delta <> digits <>;
      type Divisor_Type is delta <> digits <>;
      type Quotient_Type is delta <> digits <>;
      type Remainder_Type is delta <> digits <>;
      procedure Divide (Dividend : in Dividend_Type;
                       Divisor : in Divisor_Type;
                       Quotient : out Quotient_Type;
                       Remainder : out Remainder_Type)
      with Convention => Intrinsic;
7      end Ada.Decimal;
```

7.a **Implementation defined:** The values of named numbers in the package Decimal.

8 Max_Scale is the largest N such that $10.0^{*(-N)}$ is allowed as a decimal type's delta. Its type is *universal_integer*.

9 Min_Scale is the smallest N such that $10.0^{*(-N)}$ is allowed as a decimal type's delta. Its type is *universal_integer*.

10 Min_Delta is the smallest value allowed for *delta* in a *decimal_fixed_point_definition*. Its type is *universal_real*.

11 Max_Delta is the largest value allowed for *delta* in a *decimal_fixed_point_definition*. Its type is *universal_real*.

12 Max_Decimal_Digits is the largest value allowed for *digits* in a *decimal_fixed_point_definition*. Its type is *universal_integer*.

12.a **Reason:** The name is Max_Decimal_Digits versus Max_Digits, in order to avoid confusion with the named number System.Max_Digits relevant to floating point.

- 11 The entries are not case-sensitive. Mixed- or lower-case forms for "CR" and "DB", and lower-case forms for 'V', 'Z', and 'B', have the same effect as the upper-case symbols shown.
- 12 An occurrence of a '9' Character in the picture String represents a decimal digit position in the edited output string.
- 13 A radix control Character in the picture String indicates the position of the radix mark in the edited output string: an actual character position for '.', or an assumed position for 'V'.
- 14 A sign control Character in the picture String affects the form of the sign in the edited output string. The '<' and '>' Character values indicate parentheses for negative values. A Character '+', '-', or '<' appears either singly, signifying a fixed-position sign in the edited output, or repeated, signifying a floating-position sign that is preceded by zero or more space characters and that replaces a leading 0.
- 15 A currency control Character in the picture String indicates an occurrence of the currency string in the edited output string. The '\$' Character represents the complete currency string; the '#' Character represents one character of the currency string. A '\$' Character appears either singly, indicating a fixed-position currency string in the edited output, or repeated, indicating a floating-position currency string that occurs in place of a leading 0. A sequence of '#' Character values indicates either a fixed- or floating-position currency string, depending on context.
- 16 A zero suppression Character in the picture String allows a leading zero to be replaced by either the space character (for 'Z') or the fill character (for '*').
- 17 A simple insertion Character in the picture String represents, in general, either itself (if '/' or '0'), the space character (if 'B'), or the digits group separator character (if '_'). In some contexts it is treated as part of a floating sign, floating currency, or zero suppression string.
- 18/2 {AI95-00434-01} An example of a picture String is "<###Z_ZZ9.99>". If the currency string is "kr", the separator character is ',', and the radix mark is '.' then the edited output string values for the decimal values 32.10 and -5432.10 are "bbkrbbb32.10b" and "(bkr5,432.10)", respectively, where 'b' indicates the space character.
- 19/2 {AI95-00285-01} The generic packages Text_IO.Decimal_IO, Wide_Text_IO.Decimal_IO, and Wide_Wide_Text_IO.Decimal_IO (see A.10.9, "Input-Output for Real Types") provide text input and nonedited text output for decimal types.
- 20/2 NOTES
2 {AI95-00285-01} A picture String is of type Standard.String, for all of Text_IO Editing, Wide_Text_IO Editing, and Wide_Wide_Text_IO Editing.

Wording Changes from Ada 95

- 20.a/2 {AI95-00285-01} Added descriptions of Wide_Wide_Text_IO Editing; see F.3.5.

F.3.1 Picture String Formation

- 1/3 {AI05-0299-1} A *well-formed picture String*, or simply *picture String*, is a String value that conforms to the syntactic rules, composition constraints, and character replication conventions specified in this subclause.

Dynamic Semantics

- 2/1 *This paragraph was deleted.*

<pre> picture_string ::= fixed_\$_picture_string fixed_#_picture_string floating_currency_picture_string non_currency_picture_string </pre>	3
<pre> fixed_\$_picture_string ::= [fixed_LHS_sign] fixed_\$_char {direct_insertion} [zero_suppression] number [RHS_sign] [fixed_LHS_sign {direct_insertion}] [zero_suppression] number fixed_\$_char {direct_insertion} [RHS_sign] floating_LHS_sign number fixed_\$_char {direct_insertion} [RHS_sign] [fixed_LHS_sign] fixed_\$_char {direct_insertion} all_zero_suppression_number {direct_insertion} [RHS_sign] [fixed_LHS_sign {direct_insertion}] all_zero_suppression_number {direct_insertion} fixed_\$_char {direct_insertion} [RHS_sign] all_sign_number {direct_insertion} fixed_\$_char {direct_insertion} [RHS_sign] </pre>	4

<code>all_zero_suppression_aft_char ::= zero_suppression_char context_sensitive_insertion</code>	
<code>zero_suppression_char ::= Z *</code>	38

The following composition constraints apply to a picture String: 39

- A `floating_LHS_sign` does not have occurrences of different `LHS_Sign Character` values. 40
- If a picture String has '`<`' as `fixed_LHS_sign`, then it has '`>`' as `RHS_sign`. 41
- If a picture String has '`<`' in a `floating_LHS_sign` or in an `all_sign_number`, then it has an occurrence of '`>`'. 42
- `{8652/0088} {AI95-00153}` If a picture String has '+' or '-' as `fixed_LHS_sign`, in a `floating_LHS_sign`, or in an `all_sign_number`, then it has no `RHS_sign` or '`>`' character. 43/1
- An instance of `all_sign_number` does not have occurrences of different `sign_char Character` values. 44
- An instance of `all_currency_number` does not have occurrences of different `currency_char Character` values. 45
- An instance of `all_zero_suppression_number` does not have occurrences of different `zero_suppression_char Character` values, except for possible case differences between 'Z' and 'z'. 46

A *replicable Character* is a Character that, by the above rules, can occur in two consecutive positions in a picture String. 47

A *Character replication* is a String 48

`char & '(' & spaces & count_string & ')'` 49

where *char* is a replicable Character, *spaces* is a String (possibly empty) comprising only space Character values, and *count_string* is a String of one or more decimal digit Character values. A Character 50

replication in a picture String has the same effect as (and is said to be *equivalent to*) a String comprising n consecutive occurrences of *char*, where $n = \text{Integer}'\text{Value}(\text{count_string})$.

51 An *expanded picture String* is a picture String containing no Character replications.

51.a **Discussion:** Since 'B' is not allowed after a RHS sign, there is no need for a special rule to disallow "9.99DB(2)" as an abbreviation for "9.99DBB"

NOTES

52 3 Although a sign to the left of the number can float, a sign to the right of the number is in a fixed position.

Wording Changes from Ada 95

52.a/2 {8652/0088} {AI95-00153-01} **Corrigendum:** The picture string rules for numbers were tightened.

F.3.2 Edited Output Generation

Dynamic Semantics

1 The contents of an edited output string are based on:

- 2 • A value, Item, of some decimal type Num,
- 3 • An expanded picture String Pic_String,
- 4 • A Boolean value, Blank_When_Zero,
- 5 • A Currency string,
- 6 • A Fill character,
- 7 • A Separator character, and
- 8 • A Radix_Mark character.

9 The combination of a True value for Blank_When_Zero and a '*' character in Pic_String is inconsistent; no edited output string is defined.

9.a/2 **Reason:** {AI95-00114-01} Such a Pic_String is invalid, and any attempt to use such a string will raise Picture_Error.

10 A layout error is identified in the rules below if leading nonzero digits of Item, character values of the Currency string, or a negative sign would be truncated; in such cases no edited output string is defined.

11 The edited output string has lower bound 1 and upper bound N where $N = \text{Pic_String}'\text{Length} + \text{Currency_Length_Adjustment} - \text{Radix_Adjustment}$, and

- 12 • Currency_Length_Adjustment = Currency'Length - 1 if there is some occurrence of '\$' in Pic_String, and 0 otherwise.
- 13 • Radix_Adjustment = 1 if there is an occurrence of 'V' or 'v' in Pic_Str, and 0 otherwise.

14 Let the magnitude of Item be expressed as a base-10 number $I_p \cdots I_1.F_1 \cdots F_q$, called the *displayed magnitude* of Item, where:

- 15 • $q = \text{Min}(\text{Max}(\text{Num}'\text{Scale}, 0), n)$ where n is 0 if Pic_String has no radix and is otherwise the number of digit positions following radix in Pic_String, where a digit position corresponds to an occurrence of '9', a zero_suppression_char (for an all_zero_suppression_number), a currency_char (for an all_currency_number), or a sign_char (for an all_sign_number).
- 16 • $I_p \neq 0$ if $p > 0$.

17 If $n < \text{Num}'\text{Scale}$, then the above number is the result of rounding (away from 0 if exactly midway between values).

18 If Blank_When_Zero = True and the displayed magnitude of Item is zero, then the edited output string comprises all space character values. Otherwise, the picture String is treated as a sequence of instances of

syntactic categories based on the rules in F.3.1, and the edited output string is the concatenation of string values derived from these categories according to the following mapping rules.

Table F-1 shows the mapping from a sign control symbol to a corresponding character or string in the edited output. In the columns showing the edited output, a lower-case 'b' represents the space character. If there is no sign control symbol but the value of Item is negative, a layout error occurs and no edited output string is produced. 19

Sign Control Symbol	Edited Output for Nonnegative Number	Edited Output for Negative Number
'+'	'+'	'_'
'_'	'b'	'_'
'<'	'b'	'('
'>'	'b'	')'
"CR"	"bb"	"CR"
"DB"	"bb"	"DB"

An instance of `fixed_LHS_sign` maps to a character as shown in Table F-1. 20

An instance of `fixed_$_char` maps to Currency. 21

An instance of `direct_insertion` maps to Separator if `direct_insertion = '_'`, and to the `direct_insertion Character` otherwise. 22

An instance of `number` maps to a string *integer_part* & *radix_part* & *fraction_part* where: 23

- The string for *integer_part* is obtained as follows: 24
 1. Occurrences of '9' in `fore_digits` of `number` are replaced from right to left with the decimal digit character values for I_1, \dots, I_p , respectively. 25
 2. Each occurrence of '9' in `fore_digits` to the left of the leftmost '9' replaced according to rule 1 is replaced with '0'. 26
 3. If p exceeds the number of occurrences of '9' in `fore_digits` of `number`, then the excess leftmost digits are eligible for use in the mapping of an instance of `zero_suppression`, `floating_LHS_sign`, `floating_$_currency`, or `floating_#_currency` to the left of `number`; if there is no such instance, then a layout error occurs and no edited output string is produced. 27
- The *radix_part* is: 28
 - "" if `number` does not include a radix, if `radix = 'V'`, or if `radix = 'v'` 29
 - `Radix_Mark` if `number` includes '.' as radix 30
- The string for *fraction_part* is obtained as follows: 31
 1. Occurrences of '9' in `aft_digits` of `number` are replaced from left to right with the decimal digit character values for F_1, \dots, F_q . 32
 2. Each occurrence of '9' in `aft_digits` to the right of the rightmost '9' replaced according to rule 1 is replaced by '0'. 33

An instance of `zero_suppression` maps to the string obtained as follows: 34

- 35 1. The rightmost 'Z', 'z', or '*' Character values are replaced with the excess digits (if any) from the *integer_part* of the mapping of the number to the right of the *zero_suppression* instance,
- 36 2. A *context_sensitive_insertion* Character is replaced as though it were a *direct_insertion* Character, if it occurs to the right of some 'Z', 'z', or '*' in *zero_suppression* that has been mapped to an excess digit,
- 37 3. Each Character to the left of the leftmost Character replaced according to rule 1 above is replaced by:
 - 38 • the space character if the zero suppression Character is 'Z' or 'z', or
 - 39 • the Fill character if the zero suppression Character is '*'.
- 40 4. A layout error occurs if some excess digits remain after all 'Z', 'z', and '*' Character values in *zero_suppression* have been replaced via rule 1; no edited output string is produced.

41 An instance of *RHS_sign* maps to a character or string as shown in Table F-1.

42 An instance of *floating_LHS_sign* maps to the string obtained as follows.

- 43 1. Up to all but one of the rightmost *LHS_Sign* Character values are replaced by the excess digits (if any) from the *integer_part* of the mapping of the number to the right of the *floating_LHS_sign* instance.
- 44 2. The next Character to the left is replaced with the character given by the entry in Table F-1 corresponding to the *LHS_Sign* Character.
- 45 3. A *context_sensitive_insertion* Character is replaced as though it were a *direct_insertion* Character, if it occurs to the right of the leftmost *LHS_Sign* character replaced according to rule 1.
- 46 4. Any other Character is replaced by the space character..
- 47 5. A layout error occurs if some excess digits remain after replacement via rule 1; no edited output string is produced.

48 An instance of *fixed_#_currency* maps to the Currency string with n space character values concatenated on the left (if the instance does not follow a *radix*) or on the right (if the instance does follow a *radix*), where n is the difference between the length of the *fixed_#_currency* instance and *Currency'Length*. A layout error occurs if *Currency'Length* exceeds the length of the *fixed_#_currency* instance; no edited output string is produced.

49 An instance of *floating_\$_currency* maps to the string obtained as follows:

- 50 1. Up to all but one of the rightmost '\$' Character values are replaced with the excess digits (if any) from the *integer_part* of the mapping of the number to the right of the *floating_\$_currency* instance.
- 51 2. The next Character to the left is replaced by the Currency string.
- 52 3. A *context_sensitive_insertion* Character is replaced as though it were a *direct_insertion* Character, if it occurs to the right of the leftmost '\$' Character replaced via rule 1.
- 53 4. Each other Character is replaced by the space character.
- 54 5. A layout error occurs if some excess digits remain after replacement by rule 1; no edited output string is produced.

55 An instance of *floating_#_currency* maps to the string obtained as follows:

- 56 1. Up to all but one of the rightmost '#' Character values are replaced with the excess digits (if any) from the *integer_part* of the mapping of the number to the right of the *floating_#_currency* instance.

```

76      0.20      Picture: "-$$$$$. $$"
          Result: "bbbbbb$.20"
77      -1234.565 Picture: "<<<<_<<<. <<###>"
          Result: "bb(1,234.57DMb)" (currency = "DM")
78      12345.67  Picture: "###_###_##9.99"
          Result: "bbCHF12,345.67" (currency = "CHF")

```

Wording Changes from Ada 95

78.a/2 {8652/0089} {AI95-00070-01} **Corrigendum:** Corrected the picture string example.

F.3.3 The Package Text_IO.Editing

- 1 The package Text_IO.Editing provides a private type Picture with associated operations, and a generic package Decimal_Output. An object of type Picture is composed from a well-formed picture String (see F.3.1) and a Boolean item indicating whether a zero numeric value will result in an edited output string of all space characters. The package Decimal_Output contains edited output subprograms implementing the effects defined in F.3.2.

Static Semantics

- 2 The library package Text_IO.Editing has the following declaration:

```

3      package Ada.Text_IO.Editing is
4          type Picture is private;
5          function Valid (Pic_String      : in String;
                        Blank_When_Zero : in Boolean := False) return Boolean;
6          function To_Picture (Pic_String      : in String;
                              Blank_When_Zero : in Boolean := False)
              return Picture;
7          function Pic_String      (Pic : in Picture) return String;
          function Blank_When_Zero (Pic : in Picture) return Boolean;
8          Max_Picture_Length      : constant := implementation_defined;
9          Picture_Error            : exception;
10         Default_Currency        : constant String      := "$";
          Default_Fill             : constant Character   := '*';
          Default_Separator        : constant Character   := ',';
          Default_Radix_Mark       : constant Character   := '.';
11         generic
            type Num is delta <> digits <>;
            Default_Currency      : in String      := Text_IO.Editing.Default_Currency;
            Default_Fill          : in Character   := Text_IO.Editing.Default_Fill;
            Default_Separator     : in Character   :=
                Text_IO.Editing.Default_Separator;
            Default_Radix_Mark    : in Character   :=
                Text_IO.Editing.Default_Radix_Mark;
          package Decimal_Output is
            function Length (Pic      : in Picture;
                          Currency : in String := Default_Currency)
                return Natural;
12         function Valid (Item      : in Num;
                        Pic         : in Picture;
                        Currency    : in String := Default_Currency)
                return Boolean;

```

```

function Image (Item      : in Num;                               13
                Pic       : in Picture;
                Currency  : in String := Default_Currency;
                Fill      : in Character := Default_Fill;
                Separator  : in Character := Default_Separator;
                Radix_Mark : in Character := Default_Radix_Mark)
    return String;

procedure Put (File      : in File_Type;                          14
               Item      : in Num;
               Pic       : in Picture;
               Currency  : in String := Default_Currency;
               Fill      : in Character := Default_Fill;
               Separator  : in Character := Default_Separator;
               Radix_Mark : in Character := Default_Radix_Mark);

procedure Put (Item      : in Num;                               15
               Pic       : in Picture;
               Currency  : in String := Default_Currency;
               Fill      : in Character := Default_Fill;
               Separator  : in Character := Default_Separator;
               Radix_Mark : in Character := Default_Radix_Mark);

procedure Put (To       : out String;                             16
               Item      : in Num;
               Pic       : in Picture;
               Currency  : in String := Default_Currency;
               Fill      : in Character := Default_Fill;
               Separator  : in Character := Default_Separator;
               Radix_Mark : in Character := Default_Radix_Mark);
end Decimal_Output;
private
    ... -- not specified by the language
end Ada.Text_IO.Editing;

```

Implementation defined: The value of Max_Picture_Length in the package Text_IO.Editing 16.a

The exception Constraint_Error is raised if the Image function or any of the Put procedures is invoked with a null string for Currency. 17

```

function Valid (Pic_String : in String;                          18
                Blank_When_Zero : in Boolean := False) return Boolean;

```

Valid returns True if Pic_String is a well-formed picture String (see F.3.1) the length of whose expansion does not exceed Max_Picture_Length, and if either Blank_When_Zero is False or Pic_String contains no '*'. 19

```

function To_Picture (Pic_String : in String;                    20
                    Blank_When_Zero : in Boolean := False)
    return Picture;

```

To_Picture returns a result Picture such that the application of the function Pic_String to this result yields an expanded picture String equivalent to Pic_String, and such that Blank_When_Zero applied to the result Picture is the same value as the parameter Blank_When_Zero. Picture_Error is raised if not Valid(Pic_String, Blank_When_Zero). 21

```

function Pic_String (Pic : in Picture) return String;          22

```

```

function Blank_When_Zero (Pic : in Picture) return Boolean;

```

If Pic is To_Picture(String_Item, Boolean_Item) for some String_Item and Boolean_Item, then: 23

- Pic_String(Pic) returns an expanded picture String equivalent to String_Item and with any lower-case letter replaced with its corresponding upper-case form, and 24
- Blank_When_Zero(Pic) returns Boolean_Item. 25

If Pic_1 and Pic_2 are objects of type Picture, then "="(Pic_1, Pic_2) is True when 26

27 • Pic_String(Pic_1) = Pic_String(Pic_2), and

28 • Blank_When_Zero(Pic_1) = Blank_When_Zero(Pic_2).

29 **function** Length (Pic : **in** Picture;
 Currency : **in** String := Default_Currency)
 return Natural;

30 Length returns Pic_String(Pic)'Length + Currency_Length_Adjustment – Radix_Adjustment
 where

31 • Currency_Length_Adjustment =

32 • Currency'Length – 1 if there is some occurrence of '\$' in Pic_String(Pic), and

33 • 0 otherwise.

34 • Radix_Adjustment =

35 • 1 if there is an occurrence of 'V' or 'v' in Pic_Str(Pic), and

36 • 0 otherwise.

37 **function** Valid (Item : **in** Num;
 Pic : **in** Picture;
 Currency : **in** String := Default_Currency)
 return Boolean;

38 Valid returns True if Image(Item, Pic, Currency) does not raise Layout_Error, and returns False
 otherwise.

39 **function** Image (Item : **in** Num;
 Pic : **in** Picture;
 Currency : **in** String := Default_Currency;
 Fill : **in** Character := Default_Fill;
 Separator : **in** Character := Default_Separator;
 Radix_Mark : **in** Character := Default_Radix_Mark)
 return String;

40 Image returns the edited output String as defined in F.3.2 for Item, Pic_String(Pic),
 Blank_When_Zero(Pic), Currency, Fill, Separator, and Radix_Mark. If these rules identify a
 layout error, then Image raises the exception Layout_Error.

41 **procedure** Put (File : **in** File_Type;
 Item : **in** Num;
 Pic : **in** Picture;
 Currency : **in** String := Default_Currency;
 Fill : **in** Character := Default_Fill;
 Separator : **in** Character := Default_Separator;
 Radix_Mark : **in** Character := Default_Radix_Mark);

procedure Put (Item : **in** Num;
 Pic : **in** Picture;
 Currency : **in** String := Default_Currency;
 Fill : **in** Character := Default_Fill;
 Separator : **in** Character := Default_Separator;
 Radix_Mark : **in** Character := Default_Radix_Mark);

42 Each of these Put procedures outputs Image(Item, Pic, Currency, Fill, Separator, Radix_Mark)
 consistent with the conventions for Put for other real types in case of bounded line length (see
 A.10.6, “Get and Put Procedures”).

```

procedure Put (To      : out String;
               Item    : in Num;
               Pic     : in Picture;
               Currency : in String := Default_Currency;
               Fill    : in Character := Default_Fill;
               Separator : in Character := Default_Separator;
               Radix_Mark : in Character := Default_Radix_Mark);

```

{AI05-0264-1} Put copies Image(Item, Pic, Currency, Fill, Separator, Radix_Mark) to the given string, right justified. Otherwise, unassigned Character values in To are assigned the space character. If To'Length is less than the length of the string resulting from Image, then Layout_Error is raised. 44/3

Implementation Requirements

Max_Picture_Length shall be at least 30. The implementation shall support currency strings of length up to at least 10, both for Default_Currency in an instantiation of Decimal_Output, and for Currency in an invocation of Image or any of the Put procedures. 45

Discussion: This implies that a picture string with character replications need not be supported (i.e., To_Picture will raise Picture_Error) if its expanded form exceeds 30 characters. 45.a

NOTES

4 The rules for edited output are based on COBOL (ANSI X3.23:1985, endorsed by ISO as ISO 1989-1985), with the following differences: 46

- The COBOL provisions for picture string localization and for 'P' format are absent from Ada. 47
- The following Ada facilities are not in COBOL: 48
 - currency symbol placement after the number, 49
 - localization of edited output string for multi-character currency string values, including support for both length-preserving and length-expanding currency symbols in picture strings 50
 - localization of the radix mark, digits separator, and fill character, and 51
 - parenthesization of negative values. 52

The value of 30 for Max_Picture_Length is the same limit as in COBOL. 52.1

Reason: There are several reasons we have not adopted the COBOL-style permission to provide a single-character replacement in the picture string for the '\$' as currency symbol, or to interchange the roles of '.' and ',' in picture strings 52.a

- It would have introduced considerable complexity into Ada, as well as confusion between run-time and compile-time character interpretation, since picture Strings are dynamically computable in Ada, in contrast with COBOL 52.b
- Ada's rules for real literals provide a natural interpretation of '.' as digits separator and ',' for radix mark; it is not essential to allow these to be localized in picture strings, since Ada does not allow them to be localized in real literals. 52.c
- The COBOL restriction for the currency symbol in a picture string to be replaced by a single character currency symbol is a compromise solution. For general international usage a mechanism is needed to localize the edited output to be a multi-character currency string. Allowing a single-Character localization for the picture Character, and a multiple-character localization for the currency string, would be an unnecessary complication. 52.d

F.3.4 The Package Wide_Text_IO.Editing

Static Semantics

The child package Wide_Text_IO.Editing has the same contents as Text_IO.Editing, except that: 1

- each occurrence of Character is replaced by Wide_Character, 2
- each occurrence of Text_IO is replaced by Wide_Text_IO, 3
- the subtype of Default_Currency is Wide_String rather than String, and 4
- each occurrence of String in the generic package Decimal_Output is replaced by Wide_String. 5

5.a **Implementation defined:** The value of Max_Picture_Length in the package Wide_Text_IO.Editing

NOTES

6 5 Each of the functions Wide_Text_IO.Editing.Valid, To_Picture, and Pic_String has String (versus Wide_String) as its parameter or result subtype, since a picture String is not localizable.

F.3.5 The Package Wide_Wide_Text_IO.Editing

Static Semantics

1/2 {AI95-00285-01} The child package Wide_Wide_Text_IO.Editing has the same contents as Text_IO.Editing, except that:

- 2/2 • each occurrence of Character is replaced by Wide_Wide_Character,
- 3/2 • each occurrence of Text_IO is replaced by Wide_Wide_Text_IO,
- 4/2 • the subtype of Default_Currency is Wide_Wide_String rather than String, and
- 5/2 • each occurrence of String in the generic package Decimal_Output is replaced by Wide_Wide_String.

5.a/2 **Implementation defined:** The value of Max_Picture_Length in the package Wide_Wide_Text_IO.Editing

NOTES

6/2 6 {AI95-00285-01} Each of the functions Wide_Wide_Text_IO.Editing.Valid, To_Picture, and Pic_String has String (versus Wide_Wide_String) as its parameter or result subtype, since a picture String is not localizable.

Extensions to Ada 95

6.a/2 {AI95-00285-01} Package Wide_Wide_Text_IO.Editing is new; it supports 32-bit character strings. (Shouldn't it have been "Widest_Text_IO.Editing"? :-)

Annex G

(normative)

Numerics

- The Numerics Annex specifies 1
- features for complex arithmetic, including complex I/O; 2
 - a mode (“strict mode”), in which the predefined arithmetic operations of floating point and fixed point types and the functions and operations of various predefined packages have to provide guaranteed accuracy or conform to other numeric performance requirements, which the Numerics Annex also specifies; 3
 - a mode (“relaxed mode”), in which no accuracy or other numeric performance requirements need be satisfied, as for implementations not conforming to the Numerics Annex; 4
 - *{AI95-00296-01}* models of floating point and fixed point arithmetic on which the accuracy requirements of strict mode are based; 5/2
 - *{AI95-00296-01}* the definitions of the model-oriented attributes of floating point types that apply in the strict mode; and 6/2
 - *{AI95-00296-01}* features for the manipulation of real and complex vectors and matrices. 6.1/2

Implementation Advice

{AI05-0229-1} If Fortran (respectively, C) is widely supported in the target environment, implementations supporting the Numerics Annex should provide the child package `Interfaces.Fortran` (respectively, `Interfaces.C`) specified in Annex B and should support a *convention_identifier* of Fortran (respectively, C) for the Convention aspect (see Annex B), thus allowing Ada programs to interface with programs written in that language. 7/3

Implementation Advice: If Fortran (respectively, C) is supported in the target environment, then interfacing to Fortran (respectively, C) should be supported as specified in Annex B. 7.a.1/2

Extensions to Ada 83

This Annex is new to Ada 95. 7.a

G.1 Complex Arithmetic

Types and arithmetic operations for complex arithmetic are provided in `Generic_Complex_Types`, which is defined in G.1.1. Implementation-defined approximations to the complex analogs of the mathematical functions known as the “elementary functions” are provided by the subprograms in `Generic_Complex_Elementary_Functions`, which is defined in G.1.2. Both of these library units are generic children of the predefined package Numerics (see A.5). Nongeneric equivalents of these generic packages for each of the predefined floating point types are also provided as children of Numerics. 1

Implementation defined: The accuracy actually achieved by the complex elementary functions and by other complex arithmetic operations. 1.a

Discussion: Complex arithmetic is defined in the Numerics Annex, rather than in the core, because it is considered to be a specialized need of (some) numeric applications. 1.b

G.1.1 Complex Types

Static Semantics

1 The generic library package Numerics.Generic_Complex_Types has the following declaration:

```

2/1  {8652/0020} {AI95-00126-01} generic
    type Real is digits <>;
    package Ada.Numerics.Generic_Complex_Types is
    pragma Pure(Generic_Complex_Types);
3
    type Complex is
        record
            Re, Im : Real'Base;
        end record;
4/2  {AI95-00161-01} type Imaginary is private;
    pragma Preelaborable_Initialization(Imaginary);
5
    i : constant Imaginary;
    j : constant Imaginary;
6
    function Re (X : Complex) return Real'Base;
    function Im (X : Complex) return Real'Base;
    function Im (X : Imaginary) return Real'Base;
7
    procedure Set_Re (X : in out Complex;
                     Re : in Real'Base);
    procedure Set_Im (X : in out Complex;
                     Im : in Real'Base);
    procedure Set_Im (X : out Imaginary;
                     Im : in Real'Base);
8

private	22
type Imaginary is new Real'Base;	23
i : constant Imaginary := 1.0;	
j : constant Imaginary := 1.0;	
end Ada.Numerics.Generic_Complex_Types;	24
{8652/0020} {AI95-00126-01} The library package Numerics.Complex_Types is declared pure and defines the same types, constants, and subprograms as Numerics.Generic_Complex_Types, except that the predefined type Float is systematically substituted for Real'Base throughout. Nongeneric equivalents of Numerics.Generic_Complex_Types for each of the other predefined floating point types are defined similarly, with the names Numerics.Short_Complex_Types, Numerics.Long_Complex_Types, etc.	25/1
Reason: The nongeneric equivalents are provided to allow the programmer to construct simple mathematical applications without being required to understand and use generics.	25.a
Reason: The nongeneric equivalents all export the types Complex and Imaginary and the constants i and j (rather than uniquely named types and constants, such as Short_Complex, Long_Complex, etc.) to preserve their equivalence to actual instantiations of the generic package and to allow the programmer to change the precision of an application globally by changing a single context clause.	25.b
{AI95-00434-01} [Complex is a visible type with Cartesian components.]	26/2
Reason: The Cartesian representation is far more common than the polar representation, in practice. The accuracy of the results of the complex arithmetic operations and of the complex elementary functions is dependent on the representation; thus, implementers need to know that representation. The type is visible so that complex “literals” can be written in aggregate notation, if desired.	26.a
[Imaginary is a private type; its full type is derived from Real'Base.]	27
Reason: The Imaginary type and the constants i and j are provided for two reasons:	27.a
• They allow complex “literals” to be written in the alternate form of $a + b*i$ (or $a + b*j$), if desired. Of course, in some contexts the sum will need to be parenthesized.	27.b
• When an Ada binding to IEC 559:1989 that provides (signed) infinities as the result of operations that overflow becomes available, it will be important to allow arithmetic between pure-imaginary and complex operands without requiring the former to be represented as (or promoted to) complex values with a real component of zero. For example, the multiplication of $a + b*i$ by $d*i$ should yield $-b \cdot d + a \cdot d*i$, but if one	27.c

cannot avoid representing the pure-imaginary value $d*i$ as the complex value $0.0 + d*i$, then a NaN ("Not-a-Number") could be produced as the result of multiplying a by 0.0 (e.g., when a is infinite); the NaN could later trigger an exception. Providing the Imaginary type and overloads of the arithmetic operators for mixtures of Imaginary and Complex operands gives the programmer the same control over avoiding premature coercion of pure-imaginary values to complex as is already provided for pure-real values.

- 27.d **Reason:** The Imaginary type is private, rather than being visibly derived from RealBase, for two reasons:
- 27.e
- to preclude implicit conversions of real literals to the Imaginary type (such implicit conversions would make many common arithmetic expressions ambiguous); and
 - to suppress the implicit derivation of the multiplication, division, and absolute value operators with Imaginary operands and an Imaginary result (the result type would be incorrect).
- 27.f
- 27.g **Reason:** The base subtype RealBase is used for the component type of Complex, the parent type of Imaginary, and the parameter and result types of some of the subprograms to maximize the chances of being able to pass meaningful values into the subprograms and receive meaningful results back. The generic formal parameter Real therefore plays only one role, that of providing the precision to be maintained in complex arithmetic calculations. Thus, the subprograms in Numerics.Generic_Complex_Types share with those in Numerics.Generic_Elementary_Functions, and indeed even with the predefined arithmetic operations (see 4.5), the property of being free of range checks on input and output, i.e., of being able to exploit the base range of the relevant floating point type fully. As a result, the user loses the ability to impose application-oriented bounds on the range of values that the components of a complex variable can acquire; however, it can be argued that few, if any, applications have a naturally square domain (as opposed to a circular domain) anyway.
- 28 The arithmetic operations and the Re, Im, Modulus, Argument, and Conjugate functions have their usual mathematical meanings. When applied to a parameter of pure-imaginary type, the “imaginary-part” function Im yields the value of its parameter, as the corresponding real value. The remaining subprograms have the following meanings:
- 28.a **Reason:** The middle case can be understood by considering the parameter of pure-imaginary type to represent a complex value with a zero real part.
- 29
- The Set_Re and Set_Im procedures replace the designated component of a complex parameter with the given real value; applied to a parameter of pure-imaginary type, the Set_Im procedure replaces the value of that parameter with the imaginary value corresponding to the given real value.
- 30
- The Compose_From_Cartesian function constructs a complex value from the given real and imaginary components. If only one component is given, the other component is implicitly zero.
- 31
- The Compose_From_Polar function constructs a complex value from the given modulus (radius) and argument (angle). When the value of the parameter Modulus is positive (resp., negative), the result is the complex value represented by the point in the complex plane lying at a distance from the origin given by the absolute value of Modulus and forming an angle measured counterclockwise from the positive (resp., negative) real axis given by the value of the parameter Argument.
- 32 When the Cycle parameter is specified, the result of the Argument function and the parameter Argument of the Compose_From_Polar function are measured in units such that a full cycle of revolution has the given value; otherwise, they are measured in radians.
- 33 The computed results of the mathematically multivalued functions are rendered single-valued by the following conventions, which are meant to imply the principal branch:
- 34
- The result of the Modulus function is nonnegative.
- 35
- The result of the Argument function is in the quadrant containing the point in the complex plane represented by the parameter X. This may be any quadrant (I through IV); thus, the range of the Argument function is approximately $-\pi$ to π ($-\text{Cycle}/2.0$ to $\text{Cycle}/2.0$, if the parameter Cycle is specified). When the point represented by the parameter X lies on the negative real axis, the result approximates
- 36
- π (resp., $-\pi$) when the sign of the imaginary component of X is positive (resp., negative), if Real_Signed_Zeros is True;

- π , if Real'Signed_Zeros is False. 37
- Because a result lying on or near one of the axes may not be exactly representable, the approximation inherent in computing the result may place it in an adjacent quadrant, close to but on the wrong side of the axis. 38

Dynamic Semantics

The exception Numerics.Argument_Error is raised by the Argument and Compose_From_Polar functions with specified cycle, signaling a parameter value outside the domain of the corresponding mathematical function, when the value of the parameter Cycle is zero or negative. 39

The exception Constraint_Error is raised by the division operator when the value of the right operand is zero, and by the exponentiation operator when the value of the left operand is zero and the value of the exponent is negative, provided that Real'Machine_Overflows is True; when Real'Machine_Overflows is False, the result is unspecified. [Constraint_Error can also be raised when a finite result overflows (see G.2.6).] 40

Discussion: It is anticipated that an Ada binding to IEC 559:1989 will be developed in the future. As part of such a binding, the Machine_Overflows attribute of a conformant floating point type will be specified to yield False, which will permit implementations of the complex arithmetic operations to deliver results with an infinite component (and set the overflow flag defined by the binding) instead of raising Constraint_Error in overflow situations, when traps are disabled. Similarly, it is appropriate for the complex arithmetic operations to deliver results with infinite components (and set the zero-divide flag defined by the binding) instead of raising Constraint_Error in the situations defined above, when traps are disabled. Finally, such a binding should also specify the behavior of the complex arithmetic operations, when sensible, given operands with infinite components. 40.a

Implementation Requirements

In the implementation of Numerics.Generic_Complex_Types, the range of intermediate values allowed during the calculation of a final result shall not be affected by any range constraint of the subtype Real. 41

Implementation Note: Implementations of Numerics.Generic_Complex_Types written in Ada should therefore avoid declaring local variables of subtype Real; the subtype Real'Base should be used instead. 41.a

In the following cases, evaluation of a complex arithmetic operation shall yield the *prescribed result*, provided that the preceding rules do not call for an exception to be raised: 42

- The results of the Re, Im, and Compose_From_Cartesian functions are exact. 43
- The real (resp., imaginary) component of the result of a binary addition operator that yields a result of complex type is exact when either of its operands is of pure-imaginary (resp., real) type. 44

Ramification: The result of the addition operator is exact when one of its operands is of real type and the other is of pure-imaginary type. In this particular case, the operator is analogous to the Compose_From_Cartesian function; it performs no arithmetic. 44.a

- The real (resp., imaginary) component of the result of a binary subtraction operator that yields a result of complex type is exact when its right operand is of pure-imaginary (resp., real) type. 45
- The real component of the result of the Conjugate function for the complex type is exact. 46
- When the point in the complex plane represented by the parameter X lies on the nonnegative real axis, the Argument function yields a result of zero. 47

Discussion: Argument($X + i*Y$) is analogous to $EF.Arctan(Y, X)$, where EF is an appropriate instance of Numerics.Generic_Elementary_Functions, except when X and Y are both zero, in which case the former yields the value zero while the latter raises Numerics.Argument_Error. 47.a

- When the value of the parameter Modulus is zero, the Compose_From_Polar function yields a result of zero. 48
- When the value of the parameter Argument is equal to a multiple of the quarter cycle, the result of the Compose_From_Polar function with specified cycle lies on one of the axes. In this case, one of its components is zero, and the other has the magnitude of the parameter Modulus. 49

- 50
- Exponentiation by a zero exponent yields the value one. Exponentiation by a unit exponent yields the value of the left operand. Exponentiation of the value one yields the value one. Exponentiation of the value zero yields the value zero, provided that the exponent is nonzero. When the left operand is of pure-imaginary type, one component of the result of the exponentiation operator is zero.
- 51 When the result, or a result component, of any operator of `Numerics.Generic_Complex_Types` has a mathematical definition in terms of a single arithmetic or relational operation, that result or result component exhibits the accuracy of the corresponding operation of the type `Real`.
- 52 Other accuracy requirements for the `Modulus`, `Argument`, and `Compose_From_Polar` functions, and accuracy requirements for the multiplication of a pair of complex operands or for division by a complex operand, all of which apply only in the strict mode, are given in G.2.6.
- 53 The sign of a zero result or zero result component yielded by a complex arithmetic operation or function is implementation defined when `Real'Signed_Zeros` is `True`.
- 53.a **Implementation defined:** The sign of a zero result (or a component thereof) from any operator or function in `Numerics.Generic_Complex_Types`, when `Real'Signed_Zeros` is `True`.

Implementation Permissions

- 54 The nongeneric equivalent packages may, but need not, be actual instantiations of the generic package for the appropriate predefined type.
- 55/2 {8652/0091} {AI95-00434-01} Implementations may obtain the result of exponentiation of a complex or pure-imaginary operand by repeated complex multiplication, with arbitrary association of the factors and with a possible final complex reciprocation (when the exponent is negative). Implementations are also permitted to obtain the result of exponentiation of a complex operand, but not of a pure-imaginary operand, by converting the left operand to a polar representation; exponentiating the modulus by the given exponent; multiplying the argument by the given exponent; and reconvertng to a Cartesian representation. Because of this implementation freedom, no accuracy requirement is imposed on complex exponentiation (except for the prescribed results given above, which apply regardless of the implementation method chosen).

Implementation Advice

- 56 Because the usual mathematical meaning of multiplication of a complex operand and a real operand is that of the scaling of both components of the former by the latter, an implementation should not perform this operation by first promoting the real operand to complex type and then performing a full complex multiplication. In systems that, in the future, support an Ada binding to IEC 559:1989, the latter technique will not generate the required result when one of the components of the complex operand is infinite. (Explicit multiplication of the infinite component by the zero component obtained during promotion yields a NaN that propagates into the final result.) Analogous advice applies in the case of multiplication of a complex operand and a pure-imaginary operand, and in the case of division of a complex operand by a real or pure-imaginary operand.
- 56.a/2 **Implementation Advice:** Mixed real and complex operations (as well as pure-imaginary and complex operations) should not be performed by converting the real (resp. pure-imaginary) operand to complex.
- 57 Likewise, because the usual mathematical meaning of addition of a complex operand and a real operand is that the imaginary operand remains unchanged, an implementation should not perform this operation by first promoting the real operand to complex type and then performing a full complex addition. In implementations in which the `Signed_Zeros` attribute of the component type is `True` (and which therefore conform to IEC 559:1989 in regard to the handling of the sign of zero in predefined arithmetic operations), the latter technique will not generate the required result when the imaginary component of

the complex operand is a negatively signed zero. (Explicit addition of the negative zero to the zero obtained during promotion yields a positive zero.) Analogous advice applies in the case of addition of a complex operand and a pure-imaginary operand, and in the case of subtraction of a complex operand and a real or pure-imaginary operand.

Implementations in which `Real'Signed_Zeros` is `True` should attempt to provide a rational treatment of the signs of zero results and result components. As one example, the result of the `Argument` function should have the sign of the imaginary component of the parameter `X` when the point represented by that parameter lies on the positive real axis; as another, the sign of the imaginary component of the `Compose_From_Polar` function should be the same as (resp., the opposite of) that of the `Argument` parameter when that parameter has a value of zero and the `Modulus` parameter has a nonnegative (resp., negative) value. 58

Implementation Advice: If `Real'Signed_Zeros` is `True` for `Numerics.Generic_Complex_Types`, a rational treatment of the signs of zero results and result components should be provided. 58.a.1/3

Wording Changes from Ada 83

The semantics of `Numerics.Generic_Complex_Types` differs from `Generic_Complex_Types` as defined in ISO/IEC CD 13813 (for Ada 83) in the following ways: 58.a

- The generic package is a child of the package defining the `Argument_Error` exception. 58.b
- The nongeneric equivalents export types and constants with the same names as those exported by the generic package, rather than with names unique to the package. 58.c
- Implementations are not allowed to impose an optional restriction that the generic actual parameter associated with `Real` be unconstrained. (In view of the ability to declare variables of subtype `Real'Base` in implementations of `Numerics.Generic_Complex_Types`, this flexibility is no longer needed.) 58.d
- The dependence of the `Argument` function on the sign of a zero parameter component is tied to the value of `Real'Signed_Zeros`. 58.e
- Conformance to accuracy requirements is conditional. 58.f

Extensions to Ada 95

{AI95-00161-01} **Amendment Correction:** Added a `pragma Preelaborable_Initialization` to type `Imaginary`, so that it can be used in preelaborated units. 58.g/2

Wording Changes from Ada 95

{8652/0020} {AI95-00126-01} **Corrigendum:** Explicitly stated that the nongeneric equivalents of `Generic_Complex_Types` are pure. 58.h/2

G.1.2 Complex Elementary Functions

Static Semantics

The generic library package `Numerics.Generic_Complex_Elementary_Functions` has the following declaration: 1

```
{AI95-00434-01} with Ada.Numerics.Generic_Complex_Types; 2/2
generic
  with package Complex_Types is
    new Ada.Numerics.Generic_Complex_Types (<>);
  use Complex_Types;
package Ada.Numerics.Generic_Complex_Elementary_Functions is
  pragma Pure(Generic_Complex_Elementary_Functions);
  function Sqrt (X : Complex) return Complex; 3
  function Log (X : Complex) return Complex;
  function Exp (X : Complex) return Complex;
  function Exp (X : Imaginary) return Complex;
  function "***" (Left : Complex; Right : Complex) return Complex;
  function "***" (Left : Complex; Right : Real'Base) return Complex;
  function "***" (Left : Real'Base; Right : Complex) return Complex;
```

```

4      function Sin (X : Complex) return Complex;
      function Cos (X : Complex) return Complex;
      function Tan (X : Complex) return Complex;
      function Cot (X : Complex) return Complex;

5      function Arcsin (X : Complex) return Complex;
      function Arccos (X : Complex) return Complex;
      function Arctan (X : Complex) return Complex;
      function Arccot (X : Complex) return Complex;

6      function Sinh (X : Complex) return Complex;
      function Cosh (X : Complex) return Complex;
      function Tanh (X : Complex) return Complex;
      function Coth (X : Complex) return Complex;

7      function Arcsinh (X : Complex) return Complex;
      function Arccosh (X : Complex) return Complex;
      function Arctanh (X : Complex) return Complex;
      function Arccoth (X : Complex) return Complex;

8      end Ada.Numerics.Generic_Complex_Elementary_Functions;

```

9/1 {8652/0020} {AI95-00126-01} The library package `Numerics.Complex_Elementary_Functions` is declared pure and defines the same subprograms as `Numerics.Generic_Complex_Elementary_Functions`, except that the predefined type `Float` is systematically substituted for `Real'Base`, and the `Complex` and `Imaginary` types exported by `Numerics.Complex_Types` are systematically substituted for `Complex` and `Imaginary`, throughout. Nongeneric equivalents of `Numerics.Generic_Complex_Elementary_Functions` corresponding to each of the other predefined floating point types are defined similarly, with the names `Numerics.Short_Complex_Elementary_Functions`, `Numerics.Long_Complex_Elementary_Functions`, etc.

9.a **Reason:** The nongeneric equivalents are provided to allow the programmer to construct simple mathematical applications without being required to understand and use generics.

10 The overloading of the `Exp` function for the pure-imaginary type is provided to give the user an alternate way to compose a complex value from a given modulus and argument. In addition to `Compose_From_Polar(Rho, Theta)` (see G.1.1), the programmer may write `Rho * Exp(i * Theta)`.

11 The imaginary (resp., real) component of the parameter `X` of the forward hyperbolic (resp., trigonometric) functions and of the `Exp` function (and the parameter `X`, itself, in the case of the overloading of the `Exp` function for the pure-imaginary type) represents an angle measured in radians, as does the imaginary (resp., real) component of the result of the `Log` and inverse hyperbolic (resp., trigonometric) functions.

12 The functions have their usual mathematical meanings. However, the arbitrariness inherent in the placement of branch cuts, across which some of the complex elementary functions exhibit discontinuities, is eliminated by the following conventions:

- 13 • The imaginary component of the result of the `Sqrt` and `Log` functions is discontinuous as the parameter `X` crosses the negative real axis.
- 14 • The result of the exponentiation operator when the left operand is of complex type is discontinuous as that operand crosses the negative real axis.
- 15/2 • {AI95-00185-01} The imaginary component of the result of the `Arcsin`, `Arccos`, and `Arctanh` functions is discontinuous as the parameter `X` crosses the real axis to the left of -1.0 or the right of 1.0 .
- 16/2 • {AI95-00185-01} The real component of the result of the `Arctan` and `Arcsinh` functions is discontinuous as the parameter `X` crosses the imaginary axis below $-i$ or above i .
- 17/2 • {AI95-00185-01} The real component of the result of the `Arccot` function is discontinuous as the parameter `X` crosses the imaginary axis below $-i$ or above i .
- 18 • The imaginary component of the `Arccosh` function is discontinuous as the parameter `X` crosses the real axis to the left of 1.0 .

- The imaginary component of the result of the Arccoth function is discontinuous as the parameter X crosses the real axis between -1.0 and 1.0 . 19

Discussion: *{AI95-00185-01}* The branch cuts come from the fact that the functions in question are really multi-valued in the complex domain, and that we have to pick one *principal value* to be the result of the function. Evidently we have much freedom in choosing where the branch cuts lie. However, we are adhering to the following principles which seem to lead to the more *natural* definitions: 19.a/2

- A branch cut should not intersect the real axis at a place where the corresponding real function is well-defined (in other words, the complex function should be an extension of the corresponding real function). 19.b/2
- Because all the functions in question are analytic, to ensure power series validity for the principal value, the branch cuts should be invariant by complex conjugation. 19.c/2
- For odd functions, to ensure that the principal value remains an odd function, the branch cuts should be invariant by reflection in the origin. 19.d/2

{AI95-00185-01} The computed results of the mathematically multivalued functions are rendered single-valued by the following conventions, which are meant to imply that the principal branch is an analytic continuation of the corresponding real-valued function in Numerics.Generic_Elementary_Functions. (For Arctan and Arccot, the single-argument function in question is that obtained from the two-argument version by fixing the second argument to be its default value.) 20/2

- The real component of the result of the Sqrt and Arccosh functions is nonnegative. 21
- The same convention applies to the imaginary component of the result of the Log function as applies to the result of the natural-cycle version of the Argument function of Numerics.Generic_Complex_Types (see G.1.1). 22
- The range of the real (resp., imaginary) component of the result of the Arcsin and Arctan (resp., Arcsinh and Arctanh) functions is approximately $-\pi/2.0$ to $\pi/2.0$. 23
- The real (resp., imaginary) component of the result of the Arccos and Arccot (resp., Arccoth) functions ranges from 0.0 to approximately π . 24
- The range of the imaginary component of the result of the Arccosh function is approximately $-\pi$ to π . 25

In addition, the exponentiation operator inherits the single-valuedness of the Log function. 26

Dynamic Semantics

The exception Numerics.Argument_Error is raised by the exponentiation operator, signaling a parameter value outside the domain of the corresponding mathematical function, when the value of the left operand is zero and the real component of the exponent (or the exponent itself, when it is of real type) is zero. 27

The exception Constraint_Error is raised, signaling a pole of the mathematical function (analogous to dividing by zero), in the following cases, provided that Complex_Types.Real'Machine_Overflows is True: 28

- by the Log, Cot, and Coth functions, when the value of the parameter X is zero; 29
- by the exponentiation operator, when the value of the left operand is zero and the real component of the exponent (or the exponent itself, when it is of real type) is negative; 30
- by the Arctan and Arccot functions, when the value of the parameter X is $\pm i$; 31
- by the Arctanh and Arccoth functions, when the value of the parameter X is ± 1.0 . 32

[Constraint_Error can also be raised when a finite result overflows (see G.2.6); this may occur for parameter values sufficiently *near* poles, and, in the case of some of the functions, for parameter values having components of sufficiently large magnitude.] When Complex_Types.Real'Machine_Overflows is False, the result at poles is unspecified. 33

33.a **Reason:** The purpose of raising `Constraint_Error` (rather than `Numerics.Argument_Error`) at the poles of a function, when `Float_Type.Machine_Overflows` is `True`, is to provide continuous behavior as the actual parameters of the function approach the pole and finally reach it.

33.b **Discussion:** It is anticipated that an Ada binding to IEC 559:1989 will be developed in the future. As part of such a binding, the `Machine_Overflows` attribute of a conformant floating point type will be specified to yield `False`, which will permit implementations of the complex elementary functions to deliver results with an infinite component (and set the overflow flag defined by the binding) instead of raising `Constraint_Error` in overflow situations, when traps are disabled. Similarly, it is appropriate for the complex elementary functions to deliver results with an infinite component (and set the zero-divide flag defined by the binding) instead of raising `Constraint_Error` at poles, when traps are disabled. Finally, such a binding should also specify the behavior of the complex elementary functions, when sensible, given parameters with infinite components.

Implementation Requirements

34 In the implementation of `Numerics.Generic_Complex_Elementary_Functions`, the range of intermediate values allowed during the calculation of a final result shall not be affected by any range constraint of the subtype `Complex_Types.Real`.

34.a **Implementation Note:** Implementations of `Numerics.Generic_Complex_Elementary_Functions` written in Ada should therefore avoid declaring local variables of subtype `Complex_Types.Real`; the subtype `Complex_Types.Real/Base` should be used instead.

35 In the following cases, evaluation of a complex elementary function shall yield the *prescribed result* (or a result having the prescribed component), provided that the preceding rules do not call for an exception to be raised:

36 • When the parameter `X` has the value zero, the `Sqrt`, `Sin`, `Arcsin`, `Tan`, `Arctan`, `Sinh`, `Arcsinh`, `Tanh`, and `Arctanh` functions yield a result of zero; the `Exp`, `Cos`, and `Cosh` functions yield a result of one; the `Arccos` and `Arccot` functions yield a real result; and the `Arccoth` function yields an imaginary result.

37 • When the parameter `X` has the value one, the `Sqrt` function yields a result of one; the `Log`, `Arccos`, and `Arccosh` functions yield a result of zero; and the `Arcsin` function yields a real result.

38 • When the parameter `X` has the value -1.0 , the `Sqrt` function yields the result

39 • i (resp., $-i$), when the sign of the imaginary component of `X` is positive (resp., negative), if `Complex_Types.Real.Signed_Zeros` is `True`;

40 • i , if `Complex_Types.Real.Signed_Zeros` is `False`;

41/2 • `{AI95-00434-01}` When the parameter `X` has the value -1.0 , the `Log` function yields an imaginary result; and the `Arcsin` and `Arccos` functions yield a real result.

42 • When the parameter `X` has the value $\pm i$, the `Log` function yields an imaginary result.

43 • Exponentiation by a zero exponent yields the value one. Exponentiation by a unit exponent yields the value of the left operand (as a complex value). Exponentiation of the value one yields the value one. Exponentiation of the value zero yields the value zero.

43.a **Discussion:** It is possible to give many other prescribed results restricting the result to the real or imaginary axis when the parameter `X` is appropriately restricted to easily testable portions of the domain. We follow the proposed ISO/IEC standard for `Generic_Complex_Elementary_Functions` (for Ada 83), CD 13813, in not doing so, however.

44 Other accuracy requirements for the complex elementary functions, which apply only in the strict mode, are given in G.2.6.

45 The sign of a zero result or zero result component yielded by a complex elementary function is implementation defined when `Complex_Types.Real.Signed_Zeros` is `True`.

45.a **Implementation defined:** The sign of a zero result (or a component thereof) from any operator or function in `Numerics.Generic_Complex_Elementary_Functions`, when `Complex_Types.Real.Signed_Zeros` is `True`.

Implementation Permissions

The nongeneric equivalent packages may, but need not, be actual instantiations of the generic package with the appropriate predefined nongeneric equivalent of `Numerics.Generic_Complex_Types`; if they are, then the latter shall have been obtained by actual instantiation of `Numerics.Generic_Complex_Types`. 46

The exponentiation operator may be implemented in terms of the `Exp` and `Log` functions. Because this implementation yields poor accuracy in some parts of the domain, no accuracy requirement is imposed on complex exponentiation. 47

The implementation of the `Exp` function of a complex parameter `X` is allowed to raise the exception `Constraint_Error`, signaling overflow, when the real component of `X` exceeds an unspecified threshold that is approximately $\log(\text{Complex_Types.Real'Safe_Last})$. This permission recognizes the impracticality of avoiding overflow in the marginal case that the exponential of the real component of `X` exceeds the safe range of `Complex_Types.Real` but both components of the final result do not. Similarly, the `Sin` and `Cos` (resp., `Sinh` and `Cosh`) functions are allowed to raise the exception `Constraint_Error`, signaling overflow, when the absolute value of the imaginary (resp., real) component of the parameter `X` exceeds an unspecified threshold that is approximately $\log(\text{Complex_Types.Real'Safe_Last}) + \log(2.0)$. This permission recognizes the impracticality of avoiding overflow in the marginal case that the hyperbolic sine or cosine of the imaginary (resp., real) component of `X` exceeds the safe range of `Complex_Types.Real` but both components of the final result do not. 48

Implementation Advice

Implementations in which `Complex_Types.Real'Signed_Zeros` is `True` should attempt to provide a rational treatment of the signs of zero results and result components. For example, many of the complex elementary functions have components that are odd functions of one of the parameter components; in these cases, the result component should have the sign of the parameter component at the origin. Other complex elementary functions have zero components whose sign is opposite that of a parameter component at the origin, or is always positive or always negative. 49

Implementation Advice: If `Complex_Types.Real'Signed_Zeros` is `True` for `Numerics.Generic_Complex_Elementary_Functions`, a rational treatment of the signs of zero results and result components should be provided. 49.a.1/3

Wording Changes from Ada 83

The semantics of `Numerics.Generic_Complex_Elementary_Functions` differs from `Generic_Complex_Elementary_Functions` as defined in ISO/IEC CD 13814 (for Ada 83) in the following ways: 49.a

- The generic package is a child unit of the package defining the `Argument_Error` exception. 49.b
- The proposed `Generic_Complex_Elementary_Functions` standard (for Ada 83) specified names for the nongeneric equivalents, if provided. Here, those nongeneric equivalents are required. 49.c
- The generic package imports an instance of `Numerics.Generic_Complex_Types` rather than a long list of individual types and operations exported by such an instance. 49.d
- The dependence of the imaginary component of the `Sqrt` and `Log` functions on the sign of a zero parameter component is tied to the value of `Complex_Types.Real'Signed_Zeros`. 49.e
- Conformance to accuracy requirements is conditional. 49.f

Wording Changes from Ada 95

{8652/0020} {A195-00126-01} **Corrigendum:** Explicitly stated that the nongeneric equivalents of `Generic_Complex_Elementary_Functions` are pure. 49.g/2

{A195-00185-01} Corrected various inconsistencies in the definition of the branch cuts. 49.h/2

G.1.3 Complex Input-Output

The generic package `Text_IO.Complex_IO` defines procedures for the formatted input and output of complex values. The generic actual parameter in an instantiation of `Text_IO.Complex_IO` is an instance 1

of Numerics.Generic_Complex_Types for some floating point subtype. Exceptional conditions are reported by raising the appropriate exception defined in Text_IO.

- 1.a **Implementation Note:** An implementation of Text_IO.Complex_IO can be built around an instance of Text_IO.Float_IO for the base subtype of Complex_Types.Real, where Complex_Types is the generic formal package parameter of Text_IO.Complex_IO. There is no need for an implementation of Text_IO.Complex_IO to parse real values.

Static Semantics

- 2 The generic library package Text_IO.Complex_IO has the following declaration:
- 2.a **Ramification:** Because this is a child of Text_IO, the declarations of the visible part of Text_IO are directly visible within it.

```

3  with Ada.Numerics.Generic_Complex_Types;
   generic
     with package Complex_Types is
       new Ada.Numerics.Generic_Complex_Types (<>);
   package Ada.Text_IO.Complex_IO is
4     use Complex_Types;
5     Default_Fore : Field := 2;
     Default_Aft  : Field := Real'Digits - 1;
     Default_Exp  : Field := 3;
6     procedure Get (File : in File_Type;
                    Item  : out Complex;
                    Width : in Field := 0);
     procedure Get (Item : out Complex;
                    Width : in Field := 0);
7     procedure Put (File : in File_Type;
                    Item  : in Complex;
                    Fore  : in Field := Default_Fore;
                    Aft   : in Field := Default_Aft;
                    Exp   : in Field := Default_Exp);
     procedure Put (Item : in Complex;
                    Fore  : in Field := Default_Fore;
                    Aft   : in Field := Default_Aft;
                    Exp   : in Field := Default_Exp);
8     procedure Get (From : in String;
                    Item  : out Complex;
                    Last  : out Positive);
     procedure Put (To   : out String;
                    Item  : in Complex;
                    Aft   : in Field := Default_Aft;
                    Exp   : in Field := Default_Exp);
9     end Ada.Text_IO.Complex_IO;
```

- 9.1/2 {AI95-00328-01} The library package Complex_Text_IO defines the same subprograms as Text_IO.Complex_IO, except that the predefined type Float is systematically substituted for Real, and the type Numerics.Complex_Types.Complex is systematically substituted for Complex throughout. Nongeneric equivalents of Text_IO.Complex_IO corresponding to each of the other predefined floating point types are defined similarly, with the names Short_Complex_Text_IO, Long_Complex_Text_IO, etc.

- 9.a/2 **Reason:** The nongeneric equivalents are provided to allow the programmer to construct simple mathematical applications without being required to understand and use generics.

- 10 The semantics of the Get and Put procedures are as follows:

```

11  procedure Get (File : in File_Type;
                 Item  : out Complex;
                 Width : in Field := 0);
   procedure Get (Item : out Complex;
                 Width : in Field := 0);
```

<p><code>{8652/0092}</code> <code>{AI95-00029-01}</code> The input sequence is a pair of optionally signed real literals representing the real and imaginary components of a complex value. These components have the format defined for the corresponding Get procedure of an instance of <code>Text_IO.Float_IO</code> (see A.10.9) for the base subtype of <code>Complex_Types.Real</code>. The pair of components may be separated by a comma or surrounded by a pair of parentheses or both. Blanks are freely allowed before each of the components and before the parentheses and comma, if either is used. If the value of the parameter <code>Width</code> is zero, then</p> <ul style="list-style-type: none"> • line and page terminators are also allowed in these places; • the components shall be separated by at least one blank or line terminator if the comma is omitted; and • reading stops when the right parenthesis has been read, if the input sequence includes a left parenthesis, or when the imaginary component has been read, otherwise. <p>If a nonzero value of <code>Width</code> is supplied, then</p> <ul style="list-style-type: none"> • the components shall be separated by at least one blank if the comma is omitted; and • exactly <code>Width</code> characters are read, or the characters (possibly none) up to a line terminator, whichever comes first (blanks are included in the count). <p>Reason: The parenthesized and comma-separated form is the form produced by <code>Put</code> on output (see below), and also by list-directed output in Fortran. The other allowed forms match several common styles of edit-directed output in Fortran, allowing most preexisting Fortran data files containing complex data to be read easily. When such files contain complex values with no separation between the real and imaginary components, the user will have to read those components separately, using an instance of <code>Text_IO.Float_IO</code>.</p> <p>Returns, in the parameter <code>Item</code>, the value of type <code>Complex</code> that corresponds to the input sequence.</p> <p>The exception <code>Text_IO.Data_Error</code> is raised if the input sequence does not have the required syntax or if the components of the complex value obtained are not of the base subtype of <code>Complex_Types.Real</code>.</p> <pre> procedure Put (File : in File_Type; Item : in Complex; Fore : in Field := Default_Fore; Aft : in Field := Default_Aft; Exp : in Field := Default_Exp); procedure Put (Item : in Complex; Fore : in Field := Default_Fore; Aft : in Field := Default_Aft; Exp : in Field := Default_Exp); </pre> <p>Outputs the value of the parameter <code>Item</code> as a pair of decimal literals representing the real and imaginary components of the complex value, using the syntax of an aggregate. More specifically,</p> <ul style="list-style-type: none"> • outputs a left parenthesis; • outputs the value of the real component of the parameter <code>Item</code> with the format defined by the corresponding <code>Put</code> procedure of an instance of <code>Text_IO.Float_IO</code> for the base subtype of <code>Complex_Types.Real</code>, using the given values of <code>Fore</code>, <code>Aft</code>, and <code>Exp</code>; • outputs a comma; • outputs the value of the imaginary component of the parameter <code>Item</code> with the format defined by the corresponding <code>Put</code> procedure of an instance of <code>Text_IO.Float_IO</code> for the base subtype of <code>Complex_Types.Real</code>, using the given values of <code>Fore</code>, <code>Aft</code>, and <code>Exp</code>; • outputs a right parenthesis. <p>Discussion: If the file has a bounded line length, a line terminator may be output implicitly before any element of the sequence itemized above.</p>	<p>12/1</p> <p>13</p> <p>14</p> <p>15</p> <p>15.1</p> <p>16</p> <p>17</p> <p>17.a</p> <p>18</p> <p>19</p> <p>20</p> <p>21</p> <p>22</p> <p>23</p> <p>24</p> <p>25</p> <p>26</p> <p>26.a</p>
--	---

26.b **Discussion:** The option of outputting the complex value as a pair of reals without additional punctuation is not provided, since it can be accomplished by outputting the real and imaginary components of the complex value separately.

```
27 procedure Get (From : in String;
                Item : out Complex;
                Last : out Positive);
```

28/2 *{AI95-00434-01}* Reads a complex value from the beginning of the given string, following the same rule as the Get procedure that reads a complex value from a file, but treating the end of the string as a file terminator. Returns, in the parameter Item, the value of type Complex that corresponds to the input sequence. Returns in Last the index value such that From(Last) is the last character read.

29 The exception Text_IO.Data_Error is raised if the input sequence does not have the required syntax or if the components of the complex value obtained are not of the base subtype of Complex_Types.Real.

```
30 procedure Put (To : out String;
                Item : in Complex;
                Aft : in Field := Default_Aft;
                Exp : in Field := Default_Exp);
```

31 Outputs the value of the parameter Item to the given string as a pair of decimal literals representing the real and imaginary components of the complex value, using the syntax of an aggregate. More specifically,

- 32 • a left parenthesis, the real component, and a comma are left justified in the given string, with the real component having the format defined by the Put procedure (for output to a file) of an instance of Text_IO.Float_IO for the base subtype of Complex_Types.Real, using a value of zero for Fore and the given values of Aft and Exp;
- 33 • the imaginary component and a right parenthesis are right justified in the given string, with the imaginary component having the format defined by the Put procedure (for output to a file) of an instance of Text_IO.Float_IO for the base subtype of Complex_Types.Real, using a value for Fore that completely fills the remainder of the string, together with the given values of Aft and Exp.

33.a **Reason:** This rule is the one proposed in LSN-1051. Other rules were considered, including one that would have read “Outputs the value of the parameter Item to the given string, following the same rule as for output to a file, using a value for Fore such that the sequence of characters output exactly fills, or comes closest to filling, the string; in the latter case, the string is filled by inserting one extra blank immediately after the comma.” While this latter rule might be considered the closest analogue to the rule for output to a string in Text_IO.Float_IO, it requires a more difficult and inefficient implementation involving special cases when the integer part of one component is substantially longer than that of the other and the string is too short to allow both to be preceded by blanks. Unless such a special case applies, the latter rule might produce better columnar output if several such strings are ultimately output to a file, but very nearly the same output can be produced by outputting to the file directly, with the appropriate value of Fore; in any case, it might validly be assumed that output to a string is intended for further computation rather than for display, so that the precise formatting of the string to achieve a particular appearance is not the major concern.

34 The exception Text_IO.Layout_Error is raised if the given string is too short to hold the formatted output.

Implementation Permissions

35 Other exceptions declared (by renaming) in Text_IO may be raised by the preceding procedures in the appropriate circumstances, as for the corresponding procedures of Text_IO.Float_IO.

Extensions to Ada 95

35.a/2 *{AI95-00328-01}* Nongeneric equivalents for Text_IO.Complex_IO are added, to be consistent with all other language-defined Numerics generic packages.

Wording Changes from Ada 95

{8652/0092} {AI95-00029-01} **Corrigendum:** Clarified that the syntax of values read by `Complex_IO` is the same as that read by `Text_IO.Float_IO`. 35.b/2

G.1.4 The Package `Wide_Text_IO.Complex_IO`

Static Semantics

Implementations shall also provide the generic library package `Wide_Text_IO.Complex_IO`. Its declaration is obtained from that of `Text_IO.Complex_IO` by systematically replacing `Text_IO` by `Wide_Text_IO` and `String` by `Wide_String`; the description of its behavior is obtained by additionally replacing references to particular characters (commas, parentheses, etc.) by those for the corresponding wide characters. 1

G.1.5 The Package `Wide_Wide_Text_IO.Complex_IO`

Static Semantics

{AI95-00285-01} Implementations shall also provide the generic library package `Wide_Wide_Text_IO.Complex_IO`. Its declaration is obtained from that of `Text_IO.Complex_IO` by systematically replacing `Text_IO` by `Wide_Wide_Text_IO` and `String` by `Wide_Wide_String`; the description of its behavior is obtained by additionally replacing references to particular characters (commas, parentheses, etc.) by those for the corresponding wide wide characters. 1/2

Extensions to Ada 95

{AI95-00285-01} Package `Wide_Wide_Text_IO.Complex_IO` is new. (At least it wasn't called `Incredibly_Wide_Text_IO.Complex_IO`; maybe next time.) 1.a/2

G.2 Numeric Performance Requirements

Implementation Requirements

Implementations shall provide a user-selectable mode in which the accuracy and other numeric performance requirements detailed in the following subclauses are observed. This mode, referred to as the *strict mode*, may or may not be the default mode; it directly affects the results of the predefined arithmetic operations of real types and the results of the subprograms in children of the Numerics package, and indirectly affects the operations in other language defined packages. Implementations shall also provide the opposing mode, which is known as the *relaxed mode*. 1

Reason: On the assumption that the users of an implementation that does not support the Numerics Annex have no particular need for numerical performance, such an implementation has no obligation to meet any particular requirements in this area. On the other hand, users of an implementation that does support the Numerics Annex are provided with a way of ensuring that their programs achieve a known level of numerical performance and that the performance is portable to other such implementations. The relaxed mode is provided to allow implementers to offer an efficient but not fully accurate alternative in the case that the strict mode entails a time overhead that some users may find excessive. In some of its areas of impact, the relaxed mode may be fully equivalent to the strict mode. 1.a

Implementation Note: The relaxed mode may, for example, be used to exploit the implementation of (some of) the elementary functions in hardware, when available. Such implementations often do not meet the accuracy requirements of the strict mode, or do not meet them over the specified range of parameter values, but compensate in other ways that may be important to the user, such as their extreme speed. 1.b

Ramification: For implementations supporting the Numerics Annex, the choice of mode has no effect on the selection of a representation for a real type or on the values of attributes of a real type. 1.c

Implementation Permissions

- 2 Either mode may be the default mode.
- 2.a **Implementation defined:** Whether the strict mode or the relaxed mode is the default.
- 3 The two modes need not actually be different.

Extensions to Ada 83

- 3.a The choice between strict and relaxed numeric performance was not available in Ada 83.

G.2.1 Model of Floating Point Arithmetic

- 1 In the strict mode, the predefined operations of a floating point type shall satisfy the accuracy requirements specified here and shall avoid or signal overflow in the situations described. This behavior is presented in terms of a model of floating point arithmetic that builds on the concept of the canonical form (see A.5.3).

Static Semantics

- 2 Associated with each floating point type is an infinite set of model numbers. The model numbers of a type are used to define the accuracy requirements that have to be satisfied by certain predefined operations of the type; through certain attributes of the model numbers, they are also used to explain the meaning of a user-declared floating point type declaration. The model numbers of a derived type are those of the parent type; the model numbers of a subtype are those of its type.
- 3 The *model numbers* of a floating point type T are zero and all the values expressible in the canonical form (for the type T), in which *mantissa* has T'Model_Mantissa digits and *exponent* has a value greater than or equal to T'Model_Emin. (These attributes are defined in G.2.2.)
- 3.a **Discussion:** The model is capable of describing the behavior of most existing hardware that has a mantissa-exponent representation. As applied to a type T, it is parameterized by the values of T'Machine_Radix, T'Model_Mantissa, T'Model_Emin, T'Safe_First, and T'Safe_Last. The values of these attributes are determined by how, and how well, the hardware behaves. They in turn determine the set of model numbers and the safe range of the type, which figure in the accuracy and range (overflow avoidance) requirements.
- 3.b In hardware that is free of arithmetic anomalies, T'Model_Mantissa, T'Model_Emin, T'Safe_First, and T'Safe_Last will yield the same values as T'Machine_Mantissa, T'Machine_Emin, T'Base_First, and T'Base_Last, respectively, and the model numbers in the safe range of the type T will coincide with the machine numbers of the type T. In less perfect hardware, it is not possible for the model-oriented attributes to have these optimal values, since the hardware, by definition, and therefore the implementation, cannot conform to the stringencies of the resulting model; in this case, the values yielded by the model-oriented parameters have to be made more conservative (i.e., have to be penalized), with the result that the model numbers are more widely separated than the machine numbers, and the safe range is a subrange of the base range. The implementation will then be able to conform to the requirements of the weaker model defined by the sparser set of model numbers and the smaller safe range.
- 4 A *model interval* of a floating point type is any interval whose bounds are model numbers of the type. The *model interval* of a type T *associated with a value* v is the smallest model interval of T that includes v. (The model interval associated with a model number of a type consists of that number only.)

Implementation Requirements

- 5 The accuracy requirements for the evaluation of certain predefined operations of floating point types are as follows.
- 5.a **Discussion:** This subclause does not cover the accuracy of an operation of a static expression; such operations have to be evaluated exactly (see 4.9). It also does not cover the accuracy of the predefined attributes of a floating point subtype that yield a value of the type; such operations also yield exact results (see 3.5.8 and A.5.3).
- 6 An *operand interval* is the model interval, of the type specified for the operand of an operation, associated with the value of the operand.

For any predefined arithmetic operation that yields a result of a floating point type T, the required bounds on the result are given by a model interval of T (called the *result interval*) defined in terms of the operand values as follows: 7

- The result interval is the smallest model interval of T that includes the minimum and the maximum of all the values obtained by applying the (exact) mathematical operation to values arbitrarily selected from the respective operand intervals. 8

The result interval of an exponentiation is obtained by applying the above rule to the sequence of multiplications defined by the exponent, assuming arbitrary association of the factors, and to the final division in the case of a negative exponent. 9

The result interval of a conversion of a numeric value to a floating point type T is the model interval of T associated with the operand value, except when the source expression is of a fixed point type with a *small* that is not a power of T'Machine_Radix or is a fixed point multiplication or division either of whose operands has a *small* that is not a power of T'Machine_Radix; in these cases, the result interval is implementation defined. 10

Implementation defined: The result interval in certain cases of fixed-to-float conversion. 10.a

For any of the foregoing operations, the implementation shall deliver a value that belongs to the result interval when both bounds of the result interval are in the safe range of the result type T, as determined by the values of T'Safe_First and T'Safe_Last; otherwise, 11

- if T'Machine_Overflows is True, the implementation shall either deliver a value that belongs to the result interval or raise Constraint_Error; 12
- if T'Machine_Overflows is False, the result is implementation defined. 13

Implementation defined: The result of a floating point arithmetic operation in overflow situations, when the Machine_Overflows attribute of the result type is False. 13.a

For any predefined relation on operands of a floating point type T, the implementation may deliver any value (i.e., either True or False) obtained by applying the (exact) mathematical comparison to values arbitrarily chosen from the respective operand intervals. 14

The result of a membership test is defined in terms of comparisons of the operand value with the lower and upper bounds of the given range or type mark (the usual rules apply to these comparisons). 15

Implementation Permissions

If the underlying floating point hardware implements division as multiplication by a reciprocal, the result interval for division (and exponentiation by a negative exponent) is implementation defined. 16

Implementation defined: The result interval for division (or exponentiation by a negative exponent), when the floating point hardware implements division as multiplication by a reciprocal. 16.a

Wording Changes from Ada 83

The Ada 95 model numbers of a floating point type that are in the safe range of the type are comparable to the Ada 83 safe numbers of the type. There is no analog of the Ada 83 model numbers. The Ada 95 model numbers, when not restricted to the safe range, are an infinite set. 16.b

Inconsistencies With Ada 83

Giving the model numbers the hardware radix, instead of always a radix of two, allows (in conjunction with other changes) some borderline declared types to be represented with less precision than in Ada 83 (i.e., with single precision, whereas Ada 83 would have used double precision). Because the lower precision satisfies the requirements of the model (and did so in Ada 83 as well), this change is viewed as a desirable correction of an anomaly, rather than a worrisome inconsistency. (Of course, the wider representation chosen in Ada 83 also remains eligible for selection in Ada 95.) 16.c

16.d As an example of this phenomenon, assume that Float is represented in single precision and that a double precision type is also available. Also assume hexadecimal hardware with clean properties, for example certain IBM hardware. Then,

16.e `type T is digits Float'Digits range -Float'Last .. Float'Last;`

16.f results in T being represented in double precision in Ada 83 and in single precision in Ada 95. The latter is intuitively correct; the former is counterintuitive. The reason why the double precision type is used in Ada 83 is that Float has model and safe numbers (in Ada 83) with 21 binary digits in their mantissas, as is required to model the hypothesized hexadecimal hardware using a binary radix; thus Float'Last, which is not a model number, is slightly outside the range of safe numbers of the single precision type, making that type ineligible for selection as the representation of T even though it provides adequate precision. In Ada 95, Float'Last (the same value as before) is a model number and is in the safe range of Float on the hypothesized hardware, making Float eligible for the representation of T.

Extensions to Ada 83

16.g Giving the model numbers the hardware radix allows for practical implementations on decimal hardware.

Wording Changes from Ada 83

16.h The wording of the model of floating point arithmetic has been simplified to a large extent.

G.2.2 Model-Oriented Attributes of Floating Point Types

1 In implementations that support the Numerics Annex, the model-oriented attributes of floating point types shall yield the values defined here, in both the strict and the relaxed modes. These definitions add conditions to those in A.5.3.

Static Semantics

2 For every subtype S of a floating point type T:

3/2 {AI95-00256-01} S'Model_Mantissa

Yields the number of digits in the mantissa of the canonical form of the model numbers of T (see A.5.3). The value of this attribute shall be greater than or equal to

3.1/2 $\lceil d \cdot \log(10) / \log(T'Machine_Radix) \rceil + g$

3.2/2 where d is the requested decimal precision of T, and g is 0 if T'Machine_Radix is a positive power of 10 and 1 otherwise. In addition, T'Model_Mantissa shall be less than or equal to the value of T'Machine_Mantissa. This attribute yields a value of the type *universal_integer*.

3.a **Ramification:** S'Model_Epsilon, which is defined in terms of S'Model_Mantissa (see A.5.3), yields the absolute value of the difference between one and the next model number of the type T above one. It is equal to or larger than the absolute value of the difference between one and the next machine number of the type T above one.

4 S'Model_Emin

Yields the minimum exponent of the canonical form of the model numbers of T (see A.5.3). The value of this attribute shall be greater than or equal to the value of T'Machine_Emin. This attribute yields a value of the type *universal_integer*.

4.a **Ramification:** S'Model_Small, which is defined in terms of S'Model_Emin (see A.5.3), yields the smallest positive (nonzero) model number of the type T.

5 S'Safe_First

Yields the lower bound of the safe range of T. The value of this attribute shall be a model number of T and greater than or equal to the lower bound of the base range of T. In addition, if T is declared by a `floating_point_definition` or is derived from such a type, and the `floating_point_definition` includes a `real_range_specification` specifying a lower bound of *lb*, then the value of this attribute shall be less than or equal to *lb*; otherwise, it shall be less than or equal to $-10.0 \cdot 4^{-d}$, where d is the requested decimal precision of T. This attribute yields a value of the type *universal_real*.

S'Safe_Last	Yields the upper bound of the safe range of T . The value of this attribute shall be a model number of T and less than or equal to the upper bound of the base range of T . In addition, if T is declared by a <code>floating_point_definition</code> or is derived from such a type, and the <code>floating_point_definition</code> includes a <code>real_range_specification</code> specifying an upper bound of ub , then the value of this attribute shall be greater than or equal to ub ; otherwise, it shall be greater than or equal to $10.0^{4 \cdot d}$, where d is the requested decimal precision of T . This attribute yields a value of the type <i>universal_real</i> .	6	
S'Model	Denotes a function (of a parameter X) whose specification is given in A.5.3. If X is a model number of T , the function yields X ; otherwise, it yields the value obtained by rounding or truncating X to either one of the adjacent model numbers of T . <code>Constraint_Error</code> is raised if the resulting model number is outside the safe range of S . A zero result has the sign of X when <code>S'Signed_Zeros</code> is <code>True</code> .	7	
Subject to the constraints given above, the values of <code>S'Model_Mantissa</code> and <code>S'Safe_Last</code> are to be maximized, and the values of <code>S'Model_Emin</code> and <code>S'Safe_First</code> minimized, by the implementation as follows:			
•	First, <code>S'Model_Mantissa</code> is set to the largest value for which values of <code>S'Model_Emin</code> , <code>S'Safe_First</code> , and <code>S'Safe_Last</code> can be chosen so that the implementation satisfies the strict-mode requirements of G.2.1 in terms of the model numbers and safe range induced by these attributes.	9	
•	Next, <code>S'Model_Emin</code> is set to the smallest value for which values of <code>S'Safe_First</code> and <code>S'Safe_Last</code> can be chosen so that the implementation satisfies the strict-mode requirements of G.2.1 in terms of the model numbers and safe range induced by these attributes and the previously determined value of <code>S'Model_Mantissa</code> .	10	
•	{ <i>AI05-0092-1</i> } Finally, <code>S'Safe_First</code> and <code>S'Safe_Last</code> are set (in either order) to the smallest and largest values, respectively, for which the implementation satisfies the strict-mode requirements of G.2.1 in terms of the model numbers and safe range induced by these attributes and the previously determined values of <code>S'Model_Mantissa</code> and <code>S'Model_Emin</code> .	11/3	
Ramification: The following table shows appropriate attribute values for IEEE basic single and double precision types (ANSI/IEEE Std 754-1985, IEC 559:1989). Here, we use the names <code>IEEE_Float_32</code> and <code>IEEE_Float_64</code> , the names that would typically be declared in package <code>Interfaces</code> , in an implementation that supports IEEE arithmetic. In such an implementation, the attributes would typically be the same for <code>Standard.Float</code> and <code>Long_Float</code> , respectively.			
Attribute	IEEE_Float_32	IEEE_Float_64	11.b
'Machine_Radix	2	2	11.c
'Machine_Mantissa	24	53	
'Machine_Emin	-125	-1021	
'Machine_Emax	128	1024	
'Denorm	True	True	
'Machine_Rounds	True	True	
'Machine_Overflows	True/False	True/False	
'Signed_Zeros	should be True	should be True	
'Model_Mantissa	(same as 'Machine_Mantissa)	(same as 'Machine_Mantissa)	11.d
'Model_Emin	(same as 'Machine_Emin)	(same as 'Machine_Emin)	
'Model_Epsilon	$2.0^{**(-23)}$	$2.0^{**(-52)}$	
'Model_Small	$2.0^{**(-126)}$	$2.0^{**(-1022)}$	
'Safe_First	$-2.0^{**128} * (1.0 - 2.0^{**(-24)})$	$-2.0^{**1024} * (1.0 - 2.0^{**(-53)})$	
'Safe_Last	$2.0^{**128} * (1.0 - 2.0^{**(-24)})$	$2.0^{**1024} * (1.0 - 2.0^{**(-53)})$	
'Digits	6	15	11.e
'Base'Digits	(same as 'Digits)	(same as 'Digits)	
'First	(same as 'Safe_First)	(same as 'Safe_First)	11.f
'Last	(same as 'Safe_Last)	(same as 'Safe_Last)	
'Size	32	64	
Note: <code>'Machine_Overflows</code> can be <code>True</code> or <code>False</code> , depending on whether the Ada implementation raises <code>Constraint_Error</code> or delivers a signed infinity in overflow and zerodivide situations (and at poles of the elementary functions).			11.g

11.h/2 {AI95-00256-01} Corrected the definition of Model_Mantissa to match that given in 3.5.8.

G.2.3 Model of Fixed Point Arithmetic

1 In the strict mode, the predefined arithmetic operations of a fixed point type shall satisfy the accuracy requirements specified here and shall avoid or signal overflow in the situations described.

Implementation Requirements

2 The accuracy requirements for the predefined fixed point arithmetic operations and conversions, and the results of relations on fixed point operands, are given below.

2.a **Discussion:** This subclause does not cover the accuracy of an operation of a static expression; such operations have to be evaluated exactly (see 4.9).

3 The operands of the fixed point adding operators, absolute value, and comparisons have the same type. These operations are required to yield exact results, unless they overflow.

4 Multiplications and divisions are allowed between operands of any two fixed point types; the result has to be (implicitly or explicitly) converted to some other numeric type. For purposes of defining the accuracy rules, the multiplication or division and the conversion are treated as a single operation whose accuracy depends on three types (those of the operands and the result). For decimal fixed point types, the attribute T'Round may be used to imply explicit conversion with rounding (see 3.5.10).

5 When the result type is a floating point type, the accuracy is as given in G.2.1. For some combinations of the operand and result types in the remaining cases, the result is required to belong to a small set of values called the *perfect result set*; for other combinations, it is required merely to belong to a generally larger and implementation-defined set of values called the *close result set*. When the result type is a decimal fixed point type, the perfect result set contains a single value; thus, operations on decimal types are always fully specified.

5.a **Implementation defined:** The definition of *close result set*, which determines the accuracy of certain fixed point multiplications and divisions.

6 When one operand of a fixed-fixed multiplication or division is of type *universal_real*, that operand is not implicitly converted in the usual sense, since the context does not determine a unique target type, but the accuracy of the result of the multiplication or division (i.e., whether the result has to belong to the perfect result set or merely the close result set) depends on the value of the operand of type *universal_real* and on the types of the other operand and of the result.

6.a **Discussion:** We need not consider here the multiplication or division of two such operands, since in that case either the operation is evaluated exactly (i.e., it is an operation of a static expression all of whose operators are of a root numeric type) or it is considered to be an operation of a floating point type.

7 For a fixed point multiplication or division whose (exact) mathematical result is v , and for the conversion of a value v to a fixed point type, the perfect result set and close result set are defined as follows:

- 8 • If the result type is an ordinary fixed point type with a *small* of s ,
 - 9 • if v is an integer multiple of s , then the perfect result set contains only the value v ;
 - 10 • otherwise, it contains the integer multiple of s just below v and the integer multiple of s just above v .

11 The close result set is an implementation-defined set of consecutive integer multiples of s containing the perfect result set as a subset.

- 12 • If the result type is a decimal type with a *small* of s ,
 - 13 • if v is an integer multiple of s , then the perfect result set contains only the value v ;

- $\{AI05-0264-1\}$ otherwise, if truncation applies, then it contains only the integer multiple of s in the direction toward zero, whereas if rounding applies, then it contains only the nearest integer multiple of s (with ties broken by rounding away from zero). 14/3

The close result set is an implementation-defined set of consecutive integer multiples of s containing the perfect result set as a subset. 15

Ramification: As a consequence of subsequent rules, this case does not arise when the operand types are also decimal types. 15.a

- If the result type is an integer type, 16
 - if v is an integer, then the perfect result set contains only the value v ; 17
 - otherwise, it contains the integer nearest to the value v (if v lies equally distant from two consecutive integers, the perfect result set contains the one that is further from zero). 18

The close result set is an implementation-defined set of consecutive integers containing the perfect result set as a subset. 19

The result of a fixed point multiplication or division shall belong either to the perfect result set or to the close result set, as described below, if overflow does not occur. In the following cases, if the result type is a fixed point type, let s be its *small*; otherwise, i.e. when the result type is an integer type, let s be 1.0. 20

- For a multiplication or division neither of whose operands is of type *universal_real*, let l and r be the *smalls* of the left and right operands. For a multiplication, if $(l \cdot r) / s$ is an integer or the reciprocal of an integer (the *smalls* are said to be “compatible” in this case), the result shall belong to the perfect result set; otherwise, it belongs to the close result set. For a division, if $l / (r \cdot s)$ is an integer or the reciprocal of an integer (i.e., the *smalls* are compatible), the result shall belong to the perfect result set; otherwise, it belongs to the close result set. 21

Ramification: When the operand and result types are all decimal types, their *smalls* are necessarily compatible; the same is true when they are all ordinary fixed point types with binary *smalls*. 21.a

- For a multiplication or division having one *universal_real* operand with a value of v , note that it is always possible to factor v as an integer multiple of a “compatible” *small*, but the integer multiple may be “too big.” If there exists a factorization in which that multiple is less than some implementation-defined limit, the result shall belong to the perfect result set; otherwise, it belongs to the close result set. 22

Implementation defined: Conditions on a *universal_real* operand of a fixed point multiplication or division for which the result shall be in the *perfect result set*. 22.a

A multiplication $P * Q$ of an operand of a fixed point type F by an operand of an integer type I , or vice-versa, and a division P / Q of an operand of a fixed point type F by an operand of an integer type I , are also allowed. In these cases, the result has a type of F ; explicit conversion of the result is never required. The accuracy required in these cases is the same as that required for a multiplication $F(P * Q)$ or a division $F(P / Q)$ obtained by interpreting the operand of the integer type to have a fixed point type with a *small* of 1.0. 23

The accuracy of the result of a conversion from an integer or fixed point type to a fixed point type, or from a fixed point type to an integer type, is the same as that of a fixed point multiplication of the source value by a fixed point operand having a *small* of 1.0 and a value of 1.0, as given by the foregoing rules. The result of a conversion from a floating point type to a fixed point type shall belong to the close result set. The result of a conversion of a *universal_real* operand to a fixed point type shall belong to the perfect result set. 24

The possibility of overflow in the result of a predefined arithmetic operation or conversion yielding a result of a fixed point type T is analogous to that for floating point types, except for being related to the base range instead of the safe range. If all of the permitted results belong to the base range of T , then the implementation shall deliver one of the permitted results; otherwise, 25

- 26 • if T'Machine_Overflows is True, the implementation shall either deliver one of the permitted results or raise Constraint_Error;
- 27 • if T'Machine_Overflows is False, the result is implementation defined.

27.a **Implementation defined:** The result of a fixed point arithmetic operation in overflow situations, when the Machine_Overflows attribute of the result type is False.

Inconsistencies With Ada 83

27.b Since the values of a fixed point type are now just the integer multiples of its *small*, the possibility of using extra bits available in the chosen representation for extra accuracy rather than for increasing the base range would appear to be removed, raising the possibility that some fixed point expressions will yield less accurate results than in Ada 83. However, this is partially offset by the ability of an implementation to choose a smaller default *small* than before. Of course, if it does so for a type T then T'Small will have a different value than it previously had.

27.c The accuracy requirements in the case of incompatible *smalls* are relaxed to foster wider support for nonbinary *smalls*. If this relaxation is exploited for a type that was previously supported, lower accuracy could result; however, there is no particular incentive to exploit the relaxation in such a case.

Wording Changes from Ada 83

27.d The fixed point accuracy requirements are now expressed without reference to model or safe numbers, largely because the full generality of the former model was never exploited in the case of fixed point types (particularly in regard to operand perturbation). Although the new formulation in terms of perfect result sets and close result sets is still verbose, it can be seen to distill down to two cases:

- 27.e • a case where the result must be the exact result, if the exact result is representable, or, if not, then either one of the adjacent values of the type (in some subcases only one of those adjacent values is allowed);
- 27.f • a case where the accuracy is not specified by the language.

G.2.4 Accuracy Requirements for the Elementary Functions

1 In the strict mode, the performance of Numerics.Generic_Elementary_Functions shall be as specified here.

Implementation Requirements

2 When an exception is not raised, the result of evaluating a function in an instance *EF* of Numerics.Generic_Elementary_Functions belongs to a *result interval*, defined as the smallest model interval of *EF.Float_Type* that contains all the values of the form $f \cdot (1.0 + d)$, where f is the exact value of the corresponding mathematical function at the given parameter values, d is a real number, and $|d|$ is less than or equal to the function's *maximum relative error*. The function delivers a value that belongs to the result interval when both of its bounds belong to the safe range of *EF.Float_Type*; otherwise,

- 3 • if *EF.Float_Type*'Machine_Overflows is True, the function either delivers a value that belongs to the result interval or raises Constraint_Error, signaling overflow;
- 4 • if *EF.Float_Type*'Machine_Overflows is False, the result is implementation defined.

4.a **Implementation defined:** The result of an elementary function reference in overflow situations, when the Machine_Overflows attribute of the result type is False.

5 The maximum relative error exhibited by each function is as follows:

- 6 • $2.0 \cdot EF.Float_Type'Model_Epsilon$, in the case of the Sqrt, Sin, and Cos functions;
- 7 • $4.0 \cdot EF.Float_Type'Model_Epsilon$, in the case of the Log, Exp, Tan, Cot, and inverse trigonometric functions; and
- 8 • $8.0 \cdot EF.Float_Type'Model_Epsilon$, in the case of the forward and inverse hyperbolic functions.

9 The maximum relative error exhibited by the exponentiation operator, which depends on the values of the operands, is $(4.0 + |Right \cdot \log(Left)| / 32.0) \cdot EF.Float_Type'Model_Epsilon$.

The maximum relative error given above applies throughout the domain of the forward trigonometric functions when the Cycle parameter is specified. When the Cycle parameter is omitted, the maximum relative error given above applies only when the absolute value of the angle parameter X is less than or equal to some implementation-defined *angle threshold*, which shall be at least $EF.Float_Type'Machine_Radix$ ^[$EF.Float_Type'Mantissa/2$]. Beyond the angle threshold, the accuracy of the forward trigonometric functions is implementation defined. 10

Implementation defined: The value of the *angle threshold*, within which certain elementary functions, complex arithmetic operations, and complex elementary functions yield results conforming to a maximum relative error bound. 10.a

Implementation defined: The accuracy of certain elementary functions for parameters beyond the angle threshold. 10.b

Implementation Note: The angle threshold indirectly determines the amount of precision that the implementation has to maintain during argument reduction. 10.c

{AI95-00434-01} The prescribed results specified in A.5.1 for certain functions at particular parameter values take precedence over the maximum relative error bounds; effectively, they narrow to a single value the result interval allowed by the maximum relative error bounds. Additional rules with a similar effect are given by table G-1 for the inverse trigonometric functions, at particular parameter values for which the mathematical result is possibly not a model number of $EF.Float_Type$ (or is, indeed, even transcendental). In each table entry, the values of the parameters are such that the result lies on the axis between two quadrants; the corresponding accuracy rule, which takes precedence over the maximum relative error bounds, is that the result interval is the model interval of $EF.Float_Type$ associated with the exact mathematical result given in the table. 11/2

This paragraph was deleted. 12/1

The last line of the table is meant to apply when $EF.Float_Type'Signed_Zeros$ is False; the two lines just above it, when $EF.Float_Type'Signed_Zeros$ is True and the parameter Y has a zero value with the indicated sign. 13

Table G-1: Tightly Approximated Elementary Function Results				
Function	Value of X	Value of Y	Exact Result when Cycle Specified	Exact Result when Cycle Omitted
Arcsin	1.0	n.a.	Cycle/4.0	$\pi/2.0$
Arcsin	-1.0	n.a.	-Cycle/4.0	$-\pi/2.0$
Arccos	0.0	n.a.	Cycle/4.0	$\pi/2.0$
Arccos	-1.0	n.a.	Cycle/2.0	π
Arctan and Arccot	0.0	positive	Cycle/4.0	$\pi/2.0$
Arctan and Arccot	0.0	negative	-Cycle/4.0	$-\pi/2.0$
Arctan and Arccot	negative	+0.0	Cycle/2.0	π
Arctan and Arccot	negative	-0.0	-Cycle/2.0	$-\pi$
Arctan and Arccot	negative	0.0	Cycle/2.0	π

The amount by which the result of an inverse trigonometric function is allowed to spill over into a quadrant adjacent to the one corresponding to the principal branch, as given in A.5.1, is limited. The rule is that the result belongs to the smallest model interval of $EF.Float_Type$ that contains both boundaries of 14

the quadrant corresponding to the principal branch. This rule also takes precedence over the maximum relative error bounds, effectively narrowing the result interval allowed by them.

15 Finally, the following specifications also take precedence over the maximum relative error bounds:

- 16 • The absolute value of the result of the Sin, Cos, and Tanh functions never exceeds one.
- 17 • The absolute value of the result of the Coth function is never less than one.
- 18 • The result of the Cosh function is never less than one.

Implementation Advice

19 The versions of the forward trigonometric functions without a Cycle parameter should not be implemented by calling the corresponding version with a Cycle parameter of $2.0 * \text{Numerics.Pi}$, since this will not provide the required accuracy in some portions of the domain. For the same reason, the version of Log without a Base parameter should not be implemented by calling the corresponding version with a Base parameter of Numerics.e .

19.a.1/2 **Implementation Advice:** For elementary functions, the forward trigonometric functions without a Cycle parameter should not be implemented by calling the corresponding version with a Cycle parameter. Log without a Base parameter should not be implemented by calling Log with a Base parameter.

Wording Changes from Ada 83

19.a The semantics of `Numerics.Generic_Elementary_Functions` differs from `Generic_Elementary_Functions` as defined in ISO/IEC DIS 11430 (for Ada 83) in the following ways related to the accuracy specified for strict mode:

- 19.b • The maximum relative error bounds use the `Model_Epsilon` attribute instead of the `Base'Epsilon` attribute.
- 19.c • The accuracy requirements are expressed in terms of result intervals that are model intervals. On the one hand, this facilitates the description of the required results in the presence of underflow; on the other hand, it slightly relaxes the requirements expressed in ISO/IEC DIS 11430.

G.2.5 Performance Requirements for Random Number Generation

1 In the strict mode, the performance of `Numerics.Float_Random` and `Numerics.Discrete_Random` shall be as specified here.

Implementation Requirements

2 Two different calls to the time-dependent Reset procedure shall reset the generator to different states, provided that the calls are separated in time by at least one second and not more than fifty years.

3 The implementation's representations of generator states and its algorithms for generating random numbers shall yield a period of at least $2^{31}-2$; much longer periods are desirable but not required.

4 The implementations of `Numerics.Float_Random.Random` and `Numerics.Discrete_Random.Random` shall pass at least 85% of the individual trials in a suite of statistical tests. For `Numerics.Float_Random`, the tests are applied directly to the floating point values generated (i.e., they are not converted to integers first), while for `Numerics.Discrete_Random` they are applied to the generated values of various discrete types. Each test suite performs 6 different tests, with each test repeated 10 times, yielding a total of 60 individual trials. An individual trial is deemed to pass if the chi-square value (or other statistic) calculated for the observed counts or distribution falls within the range of values corresponding to the 2.5 and 97.5 percentage points for the relevant degrees of freedom (i.e., it shall be neither too high nor too low). For the purpose of determining the degrees of freedom, measurement categories are combined whenever the expected counts are fewer than 5.

4.a **Implementation Note:** In the floating point random number test suite, the generator is reset to a time-dependent state at the beginning of the run. The test suite incorporates the following tests, adapted from D. E. Knuth, *The Art of Computer Programming, vol. 2: Seminumerical Algorithms*. In the descriptions below, the given number of degrees of

freedom is the number before reduction due to any necessary combination of measurement categories with small expected counts; it is one less than the number of measurement categories.

- Proportional Distribution Test (a variant of the Equidistribution Test). The interval 0.0 .. 1.0 is partitioned into K subintervals. K is chosen randomly between 4 and 25 for each repetition of the test, along with the boundaries of the subintervals (subject to the constraint that at least 2 of the subintervals have a width of 0.001 or more). 5000 random floating point numbers are generated. The counts of random numbers falling into each subinterval are tallied and compared with the expected counts, which are proportional to the widths of the subintervals. The number of degrees of freedom for the chi-square test is $K-1$. 4.b
- Gap Test. The bounds of a range $A .. B$, with $0.0 \leq A < B \leq 1.0$, are chosen randomly for each repetition of the test, subject to the constraint that $0.2 \leq B-A \leq 0.6$. Random floating point numbers are generated until 5000 falling into the range $A .. B$ have been encountered. Each of these 5000 is preceded by a “gap” (of length greater than or equal to 0) of consecutive random numbers not falling into the range $A .. B$. The counts of gaps of each length from 0 to 15, and of all lengths greater than 15 lumped together, are tallied and compared with the expected counts. Let $P = B-A$. The probability that a gap has a length of L is $(1-P)^L \cdot P$ for $L \leq 15$, while the probability that a gap has a length of 16 or more is $(1-P)^{16}$. The number of degrees of freedom for the chi-square test is 16. 4.c
- Permutation Test. 5000 tuples of 4 different random floating point numbers are generated. (An entire 4-tuple is discarded in the unlikely event that it contains any two exactly equal components.) The counts of each of the $4! = 24$ possible relative orderings of the components of the 4-tuples are tallied and compared with the expected counts. Each of the possible relative orderings has an equal probability. The number of degrees of freedom for the chi-square test is 23. 4.d
- Increasing-Runs Test. Random floating point numbers are generated until 5000 increasing runs have been observed. An “increasing run” is a sequence of random numbers in strictly increasing order; it is followed by a random number that is strictly smaller than the preceding random number. (A run under construction is entirely discarded in the unlikely event that one random number is followed immediately by an exactly equal random number.) The decreasing random number that follows an increasing run is discarded and not included with the next increasing run. The counts of increasing runs of each length from 1 to 4, and of all lengths greater than 4 lumped together, are tallied and compared with the expected counts. The probability that an increasing run has a length of L is $1/L! - 1/(L+1)!$ for $L \leq 4$, while the probability that an increasing run has a length of 5 or more is $1/5!$. The number of degrees of freedom for the chi-square test is 4. 4.e
- Decreasing-Runs Test. The test is similar to the Increasing Runs Test, but with decreasing runs. 4.f
- Maximum-of- t Test (with $t = 5$). 5000 tuples of 5 random floating point numbers are generated. The maximum of the components of each 5-tuple is determined and raised to the 5th power. The uniformity of the resulting values over the range 0.0 .. 1.0 is tested as in the Proportional Distribution Test. 4.g

Implementation Note: In the discrete random number test suite, `Numerics.Discrete_Random` is instantiated as described below. The generator is reset to a time-dependent state after each instantiation. The test suite incorporates the following tests, adapted from D. E. Knuth (*op. cit.*) and other sources. The given number of degrees of freedom for the chi-square test is reduced by any necessary combination of measurement categories with small expected counts, as described above. 4.h

- Equidistribution Test. In each repetition of the test, a number R between 2 and 30 is chosen randomly, and `Numerics.Discrete_Random` is instantiated with an integer subtype whose range is $1 .. R$. 5000 integers are generated randomly from this range. The counts of occurrences of each integer in the range are tallied and compared with the expected counts, which have equal probabilities. The number of degrees of freedom for the chi-square test is $R-1$. 4.i
- Simplified Poker Test. `Numerics.Discrete_Random` is instantiated once with an enumeration subtype representing the 13 denominations (Two through Ten, Jack, Queen, King, and Ace) of an infinite deck of playing cards. 2000 “poker” hands (5-tuples of values of this subtype) are generated randomly. The counts of hands containing exactly K different denominations ($1 \leq K \leq 5$) are tallied and compared with the expected counts. The probability that a hand contains exactly K different denominations is given by a formula in Knuth. The number of degrees of freedom for the chi-square test is 4. 4.j
- Coupon Collector's Test. `Numerics.Discrete_Random` is instantiated in each repetition of the test with an integer subtype whose range is $1 .. R$, where R varies systematically from 2 to 11. Integers are generated randomly from this range until each value in the range has occurred, and the number K of integers generated is recorded. This constitutes a “coupon collector's segment” of length K . 2000 such segments are generated. The counts of segments of each length from R to $R+29$, and of all lengths greater than $R+29$ lumped together, are tallied and compared with the expected counts. The probability that a segment has any given length is given by formulas in Knuth. The number of degrees of freedom for the chi-square test is 30. 4.k
- Craps Test (Lengths of Games). `Numerics.Discrete_Random` is instantiated once with an integer subtype whose range is $1 .. 6$ (representing the six numbers on a die). 5000 craps games are played, and their lengths are recorded. (The length of a craps game is the number of rolls of the pair of dice required to produce a win or a loss. A game is won on the first roll if the dice show 7 or 11; it is lost if they show 2, 3, or 12. If the dice show some other sum on the first roll, it is called the *point*, and the game is won if and only if the point is 4.l

rolled again before a 7 is rolled.) The counts of games of each length from 1 to 18, and of all lengths greater than 18 lumped together, are tallied and compared with the expected counts. For $2 \leq S \leq 12$, let D_s be the probability that a roll of a pair of dice shows the sum S , and let $Q_s(L) = D_s \cdot (1 - (D_s + D_7))^{L-2} \cdot (D_s + D_7)$. Then, the probability that a game has a length of 1 is $D_7 + D_{11} + D_2 + D_3 + D_{12}$ and, for $L > 1$, the probability that a game has a length of L is $Q_4(L) + Q_5(L) + Q_6(L) + Q_8(L) + Q_9(L) + Q_{10}(L)$. The number of degrees of freedom for the chi-square test is 18.

- 4.m
- Craps Test (Lengths of Passes). This test is similar to the last, but enough craps games are played for 3000 losses to occur. A string of wins followed by a loss is called a *pass*, and its length is the number of wins preceding the loss. The counts of passes of each length from 0 to 7, and of all lengths greater than 7 lumped together, are tallied and compared with the expected counts. For $L \geq 0$, the probability that a pass has a length of L is $W^L \cdot (1-W)$, where W , the probability that a game ends in a win, is 244.0/495.0. The number of degrees of freedom for the chi-square test is 8.
- 4.n
- Collision Test. `Numerics.Discrete_Random` is instantiated once with an integer or enumeration type representing binary bits. 15 successive calls on the `Random` function are used to obtain the bits of a 15-bit binary integer between 0 and 32767. 3000 such integers are generated, and the number of collisions (integers previously generated) is counted and compared with the expected count. A chi-square test is not used to assess the number of collisions; rather, the limits on the number of collisions, corresponding to the 2.5 and 97.5 percentage points, are (from formulas in Knuth) 112 and 154. The test passes if and only if the number of collisions is in this range.

G.2.6 Accuracy Requirements for Complex Arithmetic

- 1 In the strict mode, the performance of `Numerics.Generic_Complex_Types` and `Numerics.Generic_Complex_Elementary_Functions` shall be as specified here.

Implementation Requirements

- 2 When an exception is not raised, the result of evaluating a real function of an instance CT of `Numerics.Generic_Complex_Types` (i.e., a function that yields a value of subtype CT .`Real` or CT .`Imaginary`) belongs to a result interval defined as for a real elementary function (see G.2.4).
- 3 When an exception is not raised, each component of the result of evaluating a complex function of such an instance, or of an instance of `Numerics.Generic_Complex_Elementary_Functions` obtained by instantiating the latter with CT (i.e., a function that yields a value of subtype CT .`Complex`), also belongs to a *result interval*. The result intervals for the components of the result are either defined by a *maximum relative error* bound or by a *maximum box error* bound. When the result interval for the real (resp., imaginary) component is defined by maximum relative error, it is defined as for that of a real function, relative to the exact value of the real (resp., imaginary) part of the result of the corresponding mathematical function. When defined by maximum box error, the result interval for a component of the result is the smallest model interval of CT .`Real` that contains all the values of the corresponding part of $f \cdot (1.0 + d)$, where f is the exact complex value of the corresponding mathematical function at the given parameter values, d is complex, and $|d|$ is less than or equal to the given maximum box error. The function delivers a value that belongs to the result interval (or a value both of whose components belong to their respective result intervals) when both bounds of the result interval(s) belong to the safe range of CT .`Real`; otherwise,
- 3.a **Discussion:** The maximum relative error could be specified separately for each component, but we do not take advantage of that freedom here.
- 3.b **Discussion:** Note that $f \cdot (1.0 + d)$ defines a small circular region of the complex plane centered at f , and the result intervals for the real and imaginary components of the result define a small rectangular box containing that circle.
- 3.c **Reason:** Box error is used when the computation of the result risks loss of significance in a component due to cancellation.
- 3.d **Ramification:** The components of a complex function that exhibits bounded relative error in each component have to have the correct sign. In contrast, one of the components of a complex function that exhibits bounded box error may have the wrong sign, since the dimensions of the box containing the result are proportional to the modulus of the mathematical result and not to either component of the mathematical result individually. Thus, for example, the box containing the computed result of a complex function whose mathematical result has a large modulus but lies very close to the imaginary axis might well straddle that axis, allowing the real component of the computed result to have

the wrong sign. In this case, the distance between the computed result and the mathematical result is, nevertheless, a small fraction of the modulus of the mathematical result.

- if `CT.Real'Machine_Overflows` is True, the function either delivers a value that belongs to the result interval (or a value both of whose components belong to their respective result intervals) or raises `Constraint_Error`, signaling overflow; 4
- if `CT.Real'Machine_Overflows` is False, the result is implementation defined. 5

Implementation defined: The result of a complex arithmetic operation or complex elementary function reference in overflow situations, when the `Machine_Overflows` attribute of the corresponding real type is False. 5.a

{AI95-00434-01} The error bounds for particular complex functions are tabulated in table G-2. In the table, the error bound is given as the coefficient of `CT.Real'Model_Epsilon`. 6/2

This paragraph was deleted. 7/1

Table G-2: Error Bounds for Particular Complex Functions			
Function or Operator	Nature of Result	Nature of Bound	Error Bound
Modulus	real	max. rel. error	3.0
Argument	real	max. rel. error	4.0
Compose_From_Polar	complex	max. rel. error	3.0
"*" (both operands complex)	complex	max. box error	5.0
"/" (right operand complex)	complex	max. box error	13.0
Sqrt	complex	max. rel. error	6.0
Log	complex	max. box error	13.0
Exp (complex parameter)	complex	max. rel. error	7.0
Exp (imaginary parameter)	complex	max. rel. error	2.0
Sin, Cos, Sinh, and Cosh	complex	max. rel. error	11.0
Tan, Cot, Tanh, and Coth	complex	max. rel. error	35.0
inverse trigonometric	complex	max. rel. error	14.0
inverse hyperbolic	complex	max. rel. error	14.0

The maximum relative error given above applies throughout the domain of the `Compose_From_Polar` function when the `Cycle` parameter is specified. When the `Cycle` parameter is omitted, the maximum relative error applies only when the absolute value of the parameter `Argument` is less than or equal to the angle threshold (see G.2.4). For the `Exp` function, and for the forward hyperbolic (resp., trigonometric) functions, the maximum relative error given above likewise applies only when the absolute value of the imaginary (resp., real) component of the parameter `X` (or the absolute value of the parameter itself, in the case of the `Exp` function with a parameter of pure-imaginary type) is less than or equal to the angle threshold. For larger angles, the accuracy is implementation defined. 8

Implementation defined: The accuracy of certain complex arithmetic operations and certain complex elementary functions for parameters (or components thereof) beyond the angle threshold. 8.a

The prescribed results specified in G.1.2 for certain functions at particular parameter values take precedence over the error bounds; effectively, they narrow to a single value the result interval allowed by the error bounds for a component of the result. Additional rules with a similar effect are given below for 9

certain inverse trigonometric and inverse hyperbolic functions, at particular parameter values for which a component of the mathematical result is transcendental. In each case, the accuracy rule, which takes precedence over the error bounds, is that the result interval for the stated result component is the model interval of *CT.Real* associated with the component's exact mathematical value. The cases in question are as follows:

- 10 • When the parameter *X* has the value zero, the real (resp., imaginary) component of the result of the *Arccot* (resp., *Arccoth*) function is in the model interval of *CT.Real* associated with the value $\pi/2.0$.
 - 11 • When the parameter *X* has the value one, the real component of the result of the *Arcsin* function is in the model interval of *CT.Real* associated with the value $\pi/2.0$.
 - 12 • When the parameter *X* has the value -1.0 , the real component of the result of the *Arcsin* (resp., *Arccos*) function is in the model interval of *CT.Real* associated with the value $-\pi/2.0$ (resp., π).
- 12.a **Discussion:** It is possible to give many other prescribed results in which a component of the parameter is restricted to a similar model interval when the parameter *X* is appropriately restricted to an easily testable portion of the domain. We follow the proposed ISO/IEC standard for *Generic_Complex_Elementary_Functions* (for Ada 83) in not doing so, however.
- 13/2 {*AI95-00434-01*} The amount by which a component of the result of an inverse trigonometric or inverse hyperbolic function is allowed to spill over into a quadrant adjacent to the one corresponding to the principal branch, as given in G.1.2, is limited. The rule is that the result belongs to the smallest model interval of *CT.Real* that contains both boundaries of the quadrant corresponding to the principal branch. This rule also takes precedence over the maximum error bounds, effectively narrowing the result interval allowed by them.
- 14 Finally, the results allowed by the error bounds are narrowed by one further rule: The absolute value of each component of the result of the *Exp* function, for a pure-imaginary parameter, never exceeds one.

Implementation Advice

- 15 The version of the *Compose_From_Polar* function without a *Cycle* parameter should not be implemented by calling the corresponding version with a *Cycle* parameter of $2.0 * \text{Numerics.Pi}$, since this will not provide the required accuracy in some portions of the domain.
- 15.a.1/2 **Implementation Advice:** For complex arithmetic, the *Compose_From_Polar* function without a *Cycle* parameter should not be implemented by calling *Compose_From_Polar* with a *Cycle* parameter.

Wording Changes from Ada 83

- 15.a The semantics of *Numerics.Generic_Complex_Types* and *Numerics.Generic_Complex_Elementary_Functions* differs from *Generic_Complex_Types* and *Generic_Complex_Elementary_Functions* as defined in ISO/IEC CDs 13813 and 13814 (for Ada 83) in ways analogous to those identified for the elementary functions in G.2.4. In addition, we do not generally specify the signs of zero results (or result components), although those proposed standards do.

G.3 Vector and Matrix Manipulation

- 1/2 {*AI95-00296-01*} Types and operations for the manipulation of real vectors and matrices are provided in *Generic_Real_Arrays*, which is defined in G.3.1. Types and operations for the manipulation of complex vectors and matrices are provided in *Generic_Complex_Arrays*, which is defined in G.3.2. Both of these library units are generic children of the predefined package *Numerics* (see A.5). Nongeneric equivalents of these packages for each of the predefined floating point types are also provided as children of *Numerics*.
- 1.a/2 **Discussion:** Vector and matrix manipulation is defined in the *Numerics Annex*, rather than in the core, because it is considered to be a specialized need of (some) numeric applications.

These packages provide facilities that are similar to and replace those found in ISO/IEC 13813:1998 *Information technology — Programming languages — Generic packages of real and complex type declarations and basic operations for Ada (including vector and matrix types)*. (The other facilities provided by that Standard were already provided in Ada 95.) In addition to the main facilities of that Standard, these packages also include subprograms for the solution of linear equations, matrix inversion, determinants, and the determination of the eigenvalues and eigenvectors of real symmetric matrices and Hermitian matrices. 1.b/2

Extensions to Ada 95

{AI95-00296-01} {AI05-0299-1} This subclause It just provides an introduction to the following subclauses. 1.c/3

G.3.1 Real Vectors and Matrices

Static Semantics

{AI95-00296-01} {AI95-00418-01} The generic library package Numerics.Generic_Real_Arrays has the following declaration: 1/2

```

generic 2/2
  type Real is digits <>;
package Ada.Numerics.Generic_Real_Arrays is
  pragma Pure(Generic_Real_Arrays);

  -- Types 3/2

  type Real_Vector is array (Integer range <>) of Real'Base; 4/2
  type Real_Matrix is array (Integer range <>, Integer range <>)
    of Real'Base;

  -- Subprograms for Real_Vector types 5/2
  -- Real_Vector arithmetic operations 6/2

  function "+" (Right : Real_Vector) return Real_Vector; 7/2
  function "-" (Right : Real_Vector) return Real_Vector;
  function "abs" (Right : Real_Vector) return Real_Vector;

  function "+" (Left, Right : Real_Vector) return Real_Vector; 8/2
  function "-" (Left, Right : Real_Vector) return Real_Vector;

  function "*" (Left, Right : Real_Vector) return Real'Base; 9/2
  function "abs" (Right : Real_Vector) return Real'Base; 10/2

  -- Real_Vector scaling operations 11/2

  function "*" (Left : Real'Base; Right : Real_Vector) 12/2
    return Real_Vector;
  function "*" (Left : Real_Vector; Right : Real'Base)
    return Real_Vector;
  function "/" (Left : Real_Vector; Right : Real'Base)
    return Real_Vector;

  -- Other Real_Vector operations 13/2

  function Unit_Vector (Index : Integer; 14/2
    Order : Positive;
    First : Integer := 1) return Real_Vector;

  -- Subprograms for Real_Matrix types 15/2
  -- Real_Matrix arithmetic operations 16/2

  function "+" (Right : Real_Matrix) return Real_Matrix; 17/2
  function "-" (Right : Real_Matrix) return Real_Matrix;
  function "abs" (Right : Real_Matrix) return Real_Matrix;
  function Transpose (X : Real_Matrix) return Real_Matrix;

  function "+" (Left, Right : Real_Matrix) return Real_Matrix; 18/2
  function "-" (Left, Right : Real_Matrix) return Real_Matrix;
  function "*" (Left, Right : Real_Matrix) return Real_Matrix;

  function "*" (Left, Right : Real_Vector) return Real_Matrix; 19/2

```

```

20/2     function "*" (Left : Real_Vector; Right : Real_Matrix)
           return Real_Vector;
function "*" (Left : Real_Matrix; Right : Real_Vector)
           return Real_Vector;
21/2     -- Real_Matrix scaling operations
22/2     function "*" (Left : Real'Base; Right : Real_Matrix)
           return Real_Matrix;
function "*" (Left : Real_Matrix; Right : Real'Base)
           return Real_Matrix;
function "/" (Left : Real_Matrix; Right : Real'Base)
           return Real_Matrix;
23/2     -- Real_Matrix inversion and related operations
24/2     function Solve (A : Real_Matrix; X : Real_Vector) return Real_Vector;
function Solve (A, X : Real_Matrix) return Real_Matrix;
function Inverse (A : Real_Matrix) return Real_Matrix;
function Determinant (A : Real_Matrix) return Real'Base;
25/2     -- Eigenvalues and vectors of a real symmetric matrix
26/2     function Eigenvalues (A : Real_Matrix) return Real_Vector;
27/2     procedure Eigensystem (A           : in Real_Matrix;
                               Values    : out Real_Vector;
                               Vectors   : out Real_Matrix);
28/2     -- Other Real_Matrix operations
29/2     function Unit_Matrix (Order           : Positive;
                              First_1, First_2 : Integer := 1)
                               return Real_Matrix;
30/2     end Ada.Numerics.Generic_Real_Arrays;
31/2     {AI95-00296-01} The library package Numerics.Real_Arrays is declared pure and defines the same types
and subprograms as Numerics.Generic_Real_Arrays, except that the predefined type Float is
systematically substituted for Real'Base throughout. Nongeneric equivalents for each of the other
predefined floating point types are defined similarly, with the names Numerics.Short_Real_Arrays,
Numerics.Long_Real_Arrays, etc.
31.a/2     Reason: The nongeneric equivalents are provided to allow the programmer to construct simple mathematical
applications without being required to understand and use generics, and to be consistent with other Numerics packages.
32/2     {AI95-00296-01} Two types are defined and exported by Numerics.Generic_Real_Arrays. The composite
type Real_Vector is provided to represent a vector with components of type Real; it is defined as an
unconstrained, one-dimensional array with an index of type Integer. The composite type Real_Matrix is
provided to represent a matrix with components of type Real; it is defined as an unconstrained, two-
dimensional array with indices of type Integer.
33/2     {AI95-00296-01} The effect of the various subprograms is as described below. In most cases the
subprograms are described in terms of corresponding scalar operations of the type Real; any exception
raised by those operations is propagated by the array operation. Moreover, the accuracy of the result for
each individual component is as defined for the scalar operation unless stated otherwise.
34/2     {AI95-00296-01} In the case of those operations which are defined to involve an inner product,
Constraint_Error may be raised if an intermediate result is outside the range of Real'Base even though the
mathematical final result would not be.
35/2     function "+" (Right : Real_Vector) return Real_Vector;
function "-" (Right : Real_Vector) return Real_Vector;
function "abs" (Right : Real_Vector) return Real_Vector;
36/2     {AI95-00296-01} Each operation returns the result of applying the corresponding operation of the
type Real to each component of Right. The index range of the result is Right'Range.

```

function "+" (Left, Right : Real_Vector) return Real_Vector;	37/2
function "-" (Left, Right : Real_Vector) return Real_Vector;	
{AI95-00296-01} Each operation returns the result of applying the corresponding operation of the type Real to each component of Left and the matching component of Right. The index range of the result is Left'Range. Constraint_Error is raised if Left'Length is not equal to Right'Length.	38/2
function "*" (Left, Right : Real_Vector) return Real'Base;	39/2
{AI95-00296-01} This operation returns the inner product of Left and Right. Constraint_Error is raised if Left'Length is not equal to Right'Length. This operation involves an inner product.	40/2
function "abs" (Right : Real_Vector) return Real'Base;	41/2
{AI95-00418-01} This operation returns the L2-norm of Right (the square root of the inner product of the vector with itself).	42/2
Discussion: Normalization of vectors is a frequent enough operation that it is useful to provide the norm as a basic operation. Furthermore, implementing the norm is not entirely straightforward, because the inner product might overflow while the final norm does not. An implementation cannot merely return Sqrt (X * X), it has to cope with a possible overflow of the inner product.	42.a/2
Implementation Note: While the definition is given in terms of an inner product, the norm doesn't "involve an inner product" in the technical sense. The reason is that it has accuracy requirements substantially different from those applicable to inner products; and that cancellations cannot occur, because all the terms are positive, so there is no possibility of intermediate overflow.	42.b/2
function "*" (Left : Real'Base; Right : Real_Vector) return Real_Vector;	43/2
{AI95-00296-01} This operation returns the result of multiplying each component of Right by the scalar Left using the "*" operation of the type Real. The index range of the result is Right'Range.	44/2
function "*" (Left : Real_Vector; Right : Real'Base) return Real_Vector;	45/2
function "/" (Left : Real_Vector; Right : Real'Base) return Real_Vector;	
{AI95-00296-01} Each operation returns the result of applying the corresponding operation of the type Real to each component of Left and to the scalar Right. The index range of the result is Left'Range.	46/2
function Unit_Vector (Index : Integer; Order : Positive; First : Integer := 1) return Real_Vector;	47/2
{AI95-00296-01} This function returns a <i>unit vector</i> with Order components and a lower bound of First. All components are set to 0.0 except for the Index component which is set to 1.0. Constraint_Error is raised if Index < First, Index > First + Order - 1 or if First + Order - 1 > Integer'Last.	48/2
function "+" (Right : Real_Matrix) return Real_Matrix;	49/2
function "-" (Right : Real_Matrix) return Real_Matrix;	
function "abs" (Right : Real_Matrix) return Real_Matrix;	
{AI95-00296-01} Each operation returns the result of applying the corresponding operation of the type Real to each component of Right. The index ranges of the result are those of Right.	50/2
function Transpose (X : Real_Matrix) return Real_Matrix;	51/2
{AI95-00296-01} This function returns the transpose of a matrix X. The first and second index ranges of the result are X'Range(2) and X'Range(1) respectively.	52/2
function "+" (Left, Right : Real_Matrix) return Real_Matrix;	53/2
function "-" (Left, Right : Real_Matrix) return Real_Matrix;	
{AI95-00296-01} Each operation returns the result of applying the corresponding operation of the type Real to each component of Left and the matching component of Right. The index ranges of the result are those of Left. Constraint_Error is raised if Left'Length(1) is not equal to Right'Length(1) or Left'Length(2) is not equal to Right'Length(2).	54/2

- 55/2 **function** "*" (Left, Right : Real_Matrix) **return** Real_Matrix;
- 56/2 {AI95-00296-01} This operation provides the standard mathematical operation for matrix multiplication. The first and second index ranges of the result are Left'Range(1) and Right'Range(2) respectively. Constraint_Error is raised if Left'Length(2) is not equal to Right'Length(1). This operation involves inner products.
- 57/2 **function** "*" (Left, Right : Real_Vector) **return** Real_Matrix;
- 58/2 {AI95-00296-01} This operation returns the outer product of a (column) vector Left by a (row) vector Right using the operation "*" of the type Real for computing the individual components. The first and second index ranges of the result are Left'Range and Right'Range respectively.
- 59/2 **function** "*" (Left : Real_Vector; Right : Real_Matrix) **return** Real_Vector;
- 60/2 {AI95-00296-01} This operation provides the standard mathematical operation for multiplication of a (row) vector Left by a matrix Right. The index range of the (row) vector result is Right'Range(2). Constraint_Error is raised if Left'Length is not equal to Right'Length(1). This operation involves inner products.
- 61/2 **function** "*" (Left : Real_Matrix; Right : Real_Vector) **return** Real_Vector;
- 62/2 {AI95-00296-01} This operation provides the standard mathematical operation for multiplication of a matrix Left by a (column) vector Right. The index range of the (column) vector result is Left'Range(1). Constraint_Error is raised if Left'Length(2) is not equal to Right'Length. This operation involves inner products.
- 63/2 **function** "*" (Left : Real'Base; Right : Real_Matrix) **return** Real_Matrix;
- 64/2 {AI95-00296-01} This operation returns the result of multiplying each component of Right by the scalar Left using the "*" operation of the type Real. The index ranges of the result are those of Right.
- 65/2 **function** "*" (Left : Real_Matrix; Right : Real'Base) **return** Real_Matrix;
function "/" (Left : Real_Matrix; Right : Real'Base) **return** Real_Matrix;
- 66/2 {AI95-00296-01} Each operation returns the result of applying the corresponding operation of the type Real to each component of Left and to the scalar Right. The index ranges of the result are those of Left.
- 67/2 **function** Solve (A : Real_Matrix; X : Real_Vector) **return** Real_Vector;
- 68/2 {AI95-00296-01} This function returns a vector Y such that X is (nearly) equal to A * Y. This is the standard mathematical operation for solving a single set of linear equations. The index range of the result is A'Range(2). Constraint_Error is raised if A'Length(1), A'Length(2), and X'Length are not equal. Constraint_Error is raised if the matrix A is ill-conditioned.
- 68.a/2 **Discussion:** The text says that Y is such that "X is (nearly) equal to A * Y" rather than "X is equal to A * Y" because rounding errors may mean that there is no value of Y such that X is exactly equal to A * Y. On the other hand it does not mean that any old rough value will do. The algorithm given under Implementation Advice should be followed.
- 68.b/2 The requirement to raise Constraint_Error if the matrix is ill-conditioned is really a reflection of what will happen if the matrix is ill-conditioned. See Implementation Advice. We do not make any attempt to define ill-conditioned formally.
- 68.c/2 These remarks apply to all versions of Solve and Inverse.
- 69/2 **function** Solve (A, X : Real_Matrix) **return** Real_Matrix;
- 70/2 {AI95-00296-01} This function returns a matrix Y such that X is (nearly) equal to A * Y. This is the standard mathematical operation for solving several sets of linear equations. The index ranges of the result are A'Range(2) and X'Range(2). Constraint_Error is raised if A'Length(1), A'Length(2), and X'Length(1) are not equal. Constraint_Error is raised if the matrix A is ill-conditioned.

- function** Inverse (A : Real_Matrix) **return** Real_Matrix; 71/2
 {AI95-00296-01} This function returns a matrix B such that A * B is (nearly) equal to the unit matrix. The index ranges of the result are A'Range(2) and A'Range(1). Constraint_Error is raised if A'Length(1) is not equal to A'Length(2). Constraint_Error is raised if the matrix A is ill-conditioned. 72/2
- function** Determinant (A : Real_Matrix) **return** Real'Base; 73/2
 {AI95-00296-01} This function returns the determinant of the matrix A. Constraint_Error is raised if A'Length(1) is not equal to A'Length(2). 74/2
- function** Eigenvalues(A : Real_Matrix) **return** Real_Vector; 75/2
 {AI95-00296-01} This function returns the eigenvalues of the symmetric matrix A as a vector sorted into order with the largest first. Constraint_Error is raised if A'Length(1) is not equal to A'Length(2). The index range of the result is A'Range(1). Argument_Error is raised if the matrix A is not symmetric. 76/2
- procedure** Eigensystem(A : **in** Real_Matrix; 77/2
 Values : **out** Real_Vector;
 Vectors : **out** Real_Matrix);
 {AI95-00296-01} {AI05-0047-1} This procedure computes both the eigenvalues and eigenvectors of the symmetric matrix A. The out parameter Values is the same as that obtained by calling the function Eigenvalues. The out parameter Vectors is a matrix whose columns are the eigenvectors of the matrix A. The order of the columns corresponds to the order of the eigenvalues. The eigenvectors are normalized and mutually orthogonal (they are orthonormal), including when there are repeated eigenvalues. Constraint_Error is raised if A'Length(1) is not equal to A'Length(2), or if Values'Range is not equal to A'Range(1), or if the index ranges of the parameter Vectors are not equal to those of A. Argument_Error is raised if the matrix A is not symmetric. Constraint_Error is also raised in implementation-defined circumstances if the algorithm used does not converge quickly enough. 78/3
- Ramification:** {AI05-0047-1} There is no requirement on the absolute direction of the returned eigenvectors. Thus they might be multiplied by -1. It is only the ratios of the components that matter. This is standard practice. 78.a/3
- function** Unit_Matrix (Order : Positive; 79/2
 First_1, First_2 : Integer := 1) **return** Real_Matrix;
 {AI95-00296-01} This function returns a square *unit matrix* with Order**2 components and lower bounds of First_1 and First_2 (for the first and second index ranges respectively). All components are set to 0.0 except for the main diagonal, whose components are set to 1.0. Constraint_Error is raised if First_1 + Order - 1 > Integer'Last or First_2 + Order - 1 > Integer'Last. 80/2

Implementation Requirements

- {AI95-00296-01} Accuracy requirements for the subprograms Solve, Inverse, Determinant, Eigenvalues and Eigensystem are implementation defined. 81/2
- Implementation defined:** The accuracy requirements for the subprograms Solve, Inverse, Determinant, Eigenvalues and Eigensystem for type Real_Matrix. 81.a/2
- For operations not involving an inner product, the accuracy requirements are those of the corresponding operations of the type Real in both the strict mode and the relaxed mode (see G.2). 82/2
- For operations involving an inner product, no requirements are specified in the relaxed mode. In the strict mode the modulus of the absolute error of the inner product $X*Y$ shall not exceed $g*\mathbf{abs}(X)*\mathbf{abs}(Y)$ where g is defined as 83/2
- $$g = X'Length * \text{Real'Machine_Radix}^{*(1 - \text{Real'Model_Mantissa})}$$
- 84/2

85/2 {AI95-00418-01} For the L2-norm, no accuracy requirements are specified in the relaxed mode. In the strict mode the relative error on the norm shall not exceed $g / 2.0 + 3.0 * \text{Real'Model_Epsilon}$ where g is defined as above.

85.a/2 **Reason:** This is simply the combination of the error on the inner product with the error on Sqrt. A first order computation would lead to $2.0 * \text{Real'Model_Epsilon}$ above, but we are adding an extra $\text{Real'Model_Epsilon}$ to account for higher order effects.

Documentation Requirements

86/2 {AI95-00296-01} Implementations shall document any techniques used to reduce cancellation errors such as extended precision arithmetic.

86.a/2 **Documentation Requirement:** Any techniques used to reduce cancellation errors in `Numerics.Generic_Real_Arrays` shall be documented.

86.b/2 **Implementation Note:** The above accuracy requirement is met by the canonical implementation of the inner product by multiplication and addition using the corresponding operations of type `Real'Base` and performing the cumulative addition using ascending indices. Note however, that some hardware provides special operations for the computation of the inner product and although these may be fast they may not meet the accuracy requirement specified. See Accuracy and Stability of Numerical Algorithms By N J Higham (ISBN 0-89871-355-2), Section 3.1.

86.c/3 {AI05-0047-1} Note moreover that the componentwise accuracy requirements are not met by subcubic methods for matrix multiplication such as that devised by Strassen. These methods, which are typically used for the fast multiplication of very large matrices (e.g. order more than a few thousands), have normwise accuracy properties. If it is desired to use such methods, then distinct subprograms should be provided (perhaps in a child package). See Section 22.2.2 in the above reference.

Implementation Permissions

87/2 {AI95-00296-01} The nongeneric equivalent packages may, but need not, be actual instantiations of the generic package for the appropriate predefined type.

Implementation Advice

88/3 {AI95-00296-01} {AI05-0264-1} Implementations should implement the `Solve` and `Inverse` functions using established techniques such as LU decomposition with row interchanges followed by back and forward substitution. Implementations are recommended to refine the result by performing an iteration on the residuals; if this is done, then it should be documented.

88.a/2 **Implementation Advice:** `Solve` and `Inverse` for `Numerics.Generic_Real_Arrays` should be implemented using established techniques such as LU decomposition and the result should be refined by an iteration on the residuals.

89/2 It is not the intention that any special provision should be made to determine whether a matrix is ill-conditioned or not. The naturally occurring overflow (including division by zero) which will result from executing these functions with an ill-conditioned matrix and thus raise `Constraint_Error` is sufficient.

89.a/2 **Discussion:** There isn't any advice for the implementation to document with this paragraph.

90/2 The test that a matrix is symmetric should be performed by using the equality operator to compare the relevant components.

90.a/2 **Implementation Advice:** The equality operator should be used to test that a matrix in `Numerics.Generic_Real_Arrays` is symmetric.

91/3 {AI05-0047-1} An implementation should minimize the circumstances under which the algorithm used for `Eigenvalues` and `Eigensystem` fails to converge.

91.a.1/3 **Implementation Advice:** An implementation should minimize the circumstances under which the algorithm used for `Numerics.Generic_Real_Arrays.Eigenvalues` and `Numerics.Generic_Real_Arrays.Eigensystem` fails to converge.

91.a/3 **Implementation Note:** J. H. Wilkinson is the acknowledged expert in this area. See for example Wilkinson, J. H., and Reinsch, C. , `Linear Algebra` , vol II of `Handbook for Automatic Computation`, Springer-Verlag, or Wilkinson, J. H., `The Algebraic Eigenvalue Problem`, Oxford University Press.

Extensions to Ada 95

{AI95-00296-01} The package `Numerics.Generic_Real_Arrays` and its nongeneric equivalents are new. 91.b/2

Wording Changes from Ada 2005

{AI05-0047-1} **Correction:** Corrected various accuracy and definition issues. 91.c/3

G.3.2 Complex Vectors and Matrices

Static Semantics

{AI95-00296-01} The generic library package `Numerics.Generic_Complex_Arrays` has the following declaration: 1/2

```

```

- 51/2 **function** Unit_Matrix (Order : Positive;
 First_1, First_2 : Integer := 1)
 return Complex_Matrix;
- 52/2 **end** Ada.Numerics.Generic_Complex_Arrays;
- 53/2 {AI95-00296-01} The library package Numerics.Complex_Arrays is declared pure and defines the same types and subprograms as Numerics.Generic_Complex_Arrays, except that the predefined type Float is systematically substituted for Real'Base, and the Real_Vector and Real_Matrix types exported by Numerics.Real_Arrays are systematically substituted for Real_Vector and Real_Matrix, and the Complex type exported by Numerics.Complex_Types is systematically substituted for Complex, throughout. Nongeneric equivalents for each of the other predefined floating point types are defined similarly, with the names Numerics.Short_Complex_Arrays, Numerics.Long_Complex_Arrays, etc.
- 54/2 {AI95-00296-01} Two types are defined and exported by Numerics.Generic_Complex_Arrays. The composite type Complex_Vector is provided to represent a vector with components of type Complex; it is defined as an unconstrained one-dimensional array with an index of type Integer. The composite type Complex_Matrix is provided to represent a matrix with components of type Complex; it is defined as an unconstrained, two-dimensional array with indices of type Integer.
- 55/2 {AI95-00296-01} The effect of the various subprograms is as described below. In many cases they are described in terms of corresponding scalar operations in Numerics.Generic_Complex_Types. Any exception raised by those operations is propagated by the array subprogram. Moreover, any constraints on the parameters and the accuracy of the result for each individual component are as defined for the scalar operation.
- 56/2 {AI95-00296-01} In the case of those operations which are defined to *involve an inner product*, Constraint_Error may be raised if an intermediate result has a component outside the range of Real'Base even though the final mathematical result would not.
- 56.a/3 **Discussion:** {AI05-0047-1} An inner product never involves implicit complex conjugation. If the product of a vector with the conjugate of another (or the same) vector is required, then this has to be stated explicitly by writing for example $X * \text{Conjugate}(Y)$. This mimics the usual mathematical notation.
- 57/2 **function** Re (X : Complex_Vector) **return** Real_Vector;
 function Im (X : Complex_Vector) **return** Real_Vector;
- 58/2 {AI95-00296-01} Each function returns a vector of the specified Cartesian components of X. The index range of the result is X'Range.
- 59/2 **procedure** Set_Re (X : **in out** Complex_Vector; Re : **in** Real_Vector);
 procedure Set_Im (X : **in out** Complex_Vector; Im : **in** Real_Vector);
- 60/2 {AI95-00296-01} Each procedure replaces the specified (Cartesian) component of each of the components of X by the value of the matching component of Re or Im; the other (Cartesian) component of each of the components is unchanged. Constraint_Error is raised if X'Length is not equal to Re'Length or Im'Length.
- 61/2 **function** Compose_From_Cartesian (Re : Real_Vector)
 return Complex_Vector;
 function Compose_From_Cartesian (Re, Im : Real_Vector)
 return Complex_Vector;
- 62/2 {AI95-00296-01} Each function constructs a vector of Complex results (in Cartesian representation) formed from given vectors of Cartesian components; when only the real components are given, imaginary components of zero are assumed. The index range of the result is Re'Range. Constraint_Error is raised if Re'Length is not equal to Im'Length.

function Modulus (X : Complex_Vector) return Real_Vector;	63/2
function "abs" (Right : Complex_Vector) return Real_Vector renames Modulus;	
function Argument (X : Complex_Vector) return Real_Vector;	
function Argument (X : Complex_Vector; Cycle : Real'Base) return Real_Vector;	
{AI95-00296-01} Each function calculates and returns a vector of the specified polar components of X or Right using the corresponding function in numerics.generic_complex_types. The index range of the result is X'Range or Right'Range.	64/2
function Compose_From_Polar (Modulus, Argument : Real_Vector) return Complex_Vector;	65/2
function Compose_From_Polar (Modulus, Argument : Real_Vector; Cycle : Real'Base) return Complex_Vector;	
{AI95-00296-01} Each function constructs a vector of Complex results (in Cartesian representation) formed from given vectors of polar components using the corresponding function in numerics.generic_complex_types on matching components of Modulus and Argument. The index range of the result is Modulus'Range. Constraint_Error is raised if Modulus'Length is not equal to Argument'Length.	66/2
function "+" (Right : Complex_Vector) return Complex_Vector;	67/2
function "-" (Right : Complex_Vector) return Complex_Vector;	
{AI95-00296-01} Each operation returns the result of applying the corresponding operation in numerics.generic_complex_types to each component of Right. The index range of the result is Right'Range.	68/2
function Conjugate (X : Complex_Vector) return Complex_Vector;	69/2
{AI95-00296-01} This function returns the result of applying the appropriate function Conjugate in numerics.generic_complex_types to each component of X. The index range of the result is X'Range.	70/2
function "+" (Left, Right : Complex_Vector) return Complex_Vector;	71/2
function "-" (Left, Right : Complex_Vector) return Complex_Vector;	
{AI95-00296-01} Each operation returns the result of applying the corresponding operation in numerics.generic_complex_types to each component of Left and the matching component of Right. The index range of the result is Left'Range. Constraint_Error is raised if Left'Length is not equal to Right'Length.	72/2
function "*" (Left, Right : Complex_Vector) return Complex;	73/2
{AI95-00296-01} This operation returns the inner product of Left and Right. Constraint_Error is raised if Left'Length is not equal to Right'Length. This operation involves an inner product.	74/2
{AI05-0047-1} function "abs" (Right : Complex_Vector) return Real'Base;	75/3
{AI95-00418-01} This operation returns the Hermitian L2-norm of Right (the square root of the inner product of the vector with its conjugate).	76/2
Implementation Note: While the definition is given in terms of an inner product, the norm doesn't "involve an inner product" in the technical sense. The reason is that it has accuracy requirements substantially different from those applicable to inner products; and that cancellations cannot occur, because all the terms are positive, so there is no possibility of intermediate overflow.	76.a/2

```

77/2  function "+" (Left  : Real_Vector;
                Right : Complex_Vector) return Complex_Vector;
function "+" (Left  : Complex_Vector;
                Right : Real_Vector)   return Complex_Vector;
function "-" (Left  : Real_Vector;
                Right : Complex_Vector) return Complex_Vector;
function "-" (Left  : Complex_Vector;
                Right : Real_Vector)   return Complex_Vector;

```

78/2 {AI95-00296-01} Each operation returns the result of applying the corresponding operation in `numerics.generic_complex_types` to each component of `Left` and the matching component of `Right`. The index range of the result is `Left'Range`. `Constraint_Error` is raised if `Left'Length` is not equal to `Right'Length`.

```

79/2  function "*" (Left  : Real_Vector;   Right : Complex_Vector) return Complex;
function "*" (Left  : Complex_Vector; Right : Real_Vector)   return Complex;

```

80/2 {AI95-00296-01} Each operation returns the inner product of `Left` and `Right`. `Constraint_Error` is raised if `Left'Length` is not equal to `Right'Length`. These operations involve an inner product.

```

81/2  function "*" (Left : Complex; Right : Complex_Vector) return Complex_Vector;

```

82/2 {AI95-00296-01} This operation returns the result of multiplying each component of `Right` by the complex number `Left` using the appropriate operation `"*"` in `numerics.generic_complex_types`. The index range of the result is `Right'Range`.

```

83/2  function "*" (Left : Complex_Vector; Right : Complex) return Complex_Vector;
function "/" (Left : Complex_Vector; Right : Complex) return Complex_Vector;

```

84/2 {AI95-00296-01} Each operation returns the result of applying the corresponding operation in `numerics.generic_complex_types` to each component of the vector `Left` and the complex number `Right`. The index range of the result is `Left'Range`.

```

85/2  function "*" (Left : Real'Base;
                Right : Complex_Vector) return Complex_Vector;

```

86/2 {AI95-00296-01} This operation returns the result of multiplying each component of `Right` by the real number `Left` using the appropriate operation `"*"` in `numerics.generic_complex_types`. The index range of the result is `Right'Range`.

```

87/2  function "*" (Left : Complex_Vector;
                Right : Real'Base) return Complex_Vector;
function "/" (Left : Complex_Vector;
                Right : Real'Base) return Complex_Vector;

```

88/2 {AI95-00296-01} Each operation returns the result of applying the corresponding operation in `numerics.generic_complex_types` to each component of the vector `Left` and the real number `Right`. The index range of the result is `Left'Range`.

```

89/2  function Unit_Vector (Index : Integer;
                        Order : Positive;
                        First : Integer := 1) return Complex_Vector;

```

90/2 {AI95-00296-01} This function returns a *unit vector* with `Order` components and a lower bound of `First`. All components are set to (0.0, 0.0) except for the `Index` component which is set to (1.0, 0.0). `Constraint_Error` is raised if `Index < First`, `Index > First + Order - 1`, or if `First + Order - 1 > Integer'Last`.

```

91/2  function Re (X : Complex_Matrix) return Real_Matrix;
function Im (X : Complex_Matrix) return Real_Matrix;

```

92/2 {AI95-00296-01} Each function returns a matrix of the specified Cartesian components of `X`. The index ranges of the result are those of `X`.

procedure Set_Re (X : in out Complex_Matrix; Re : in Real_Matrix);	93/2
procedure Set_Im (X : in out Complex_Matrix; Im : in Real_Matrix);	
{AI95-00296-01} Each procedure replaces the specified (Cartesian) component of each of the components of X by the value of the matching component of Re or Im; the other (Cartesian) component of each of the components is unchanged. Constraint_Error is raised if X'Length(1) is not equal to Re'Length(1) or Im'Length(1) or if X'Length(2) is not equal to Re'Length(2) or Im'Length(2).	94/2
function Compose_From_Cartesian (Re : Real_Matrix)	95/2
return Complex_Matrix;	
function Compose_From_Cartesian (Re, Im : Real_Matrix)	
return Complex_Matrix;	
{AI95-00296-01} Each function constructs a matrix of Complex results (in Cartesian representation) formed from given matrices of Cartesian components; when only the real components are given, imaginary components of zero are assumed. The index ranges of the result are those of Re. Constraint_Error is raised if Re'Length(1) is not equal to Im'Length(1) or Re'Length(2) is not equal to Im'Length(2).	96/2
function Modulus (X : Complex_Matrix) return Real_Matrix;	97/2
function "abs" (Right : Complex_Matrix) return Real_Matrix	
renames Modulus;	
function Argument (X : Complex_Matrix) return Real_Matrix;	
function Argument (X : Complex_Matrix;	
Cycle : Real'Base) return Real_Matrix;	
{AI95-00296-01} Each function calculates and returns a matrix of the specified polar components of X or Right using the corresponding function in numerics.generic_complex_types. The index ranges of the result are those of X or Right.	98/2
function Compose_From_Polar (Modulus, Argument : Real_Matrix)	99/2
return Complex_Matrix;	
function Compose_From_Polar (Modulus, Argument : Real_Matrix;	
Cycle : Real'Base)	
return Complex_Matrix;	
{AI95-00296-01} Each function constructs a matrix of Complex results (in Cartesian representation) formed from given matrices of polar components using the corresponding function in numerics.generic_complex_types on matching components of Modulus and Argument. The index ranges of the result are those of Modulus. Constraint_Error is raised if Modulus'Length(1) is not equal to Argument'Length(1) or Modulus'Length(2) is not equal to Argument'Length(2).	100/2
function "+" (Right : Complex_Matrix) return Complex_Matrix;	101/2
function "-" (Right : Complex_Matrix) return Complex_Matrix;	
{AI95-00296-01} Each operation returns the result of applying the corresponding operation in numerics.generic_complex_types to each component of Right. The index ranges of the result are those of Right.	102/2
function Conjugate (X : Complex_Matrix) return Complex_Matrix;	103/2
{AI95-00296-01} This function returns the result of applying the appropriate function Conjugate in numerics.generic_complex_types to each component of X. The index ranges of the result are those of X.	104/2
function Transpose (X : Complex_Matrix) return Complex_Matrix;	105/2
{AI95-00296-01} This function returns the transpose of a matrix X. The first and second index ranges of the result are X'Range(2) and X'Range(1) respectively.	106/2

- 107/2 **function** "+" (Left, Right : Complex_Matrix) **return** Complex_Matrix;
function "-" (Left, Right : Complex_Matrix) **return** Complex_Matrix;
- 108/2 {AI95-00296-01} Each operation returns the result of applying the corresponding operation in `numerics.generic_complex_types` to each component of Left and the matching component of Right. The index ranges of the result are those of Left. `Constraint_Error` is raised if `Left'Length(1)` is not equal to `Right'Length(1)` or `Left'Length(2)` is not equal to `Right'Length(2)`.
- 109/2 **function** "*" (Left, Right : Complex_Matrix) **return** Complex_Matrix;
- 110/2 {AI95-00296-01} This operation provides the standard mathematical operation for matrix multiplication. The first and second index ranges of the result are `Left'Range(1)` and `Right'Range(2)` respectively. `Constraint_Error` is raised if `Left'Length(2)` is not equal to `Right'Length(1)`. This operation involves inner products.
- 111/2 **function** "*" (Left, Right : Complex_Vector) **return** Complex_Matrix;
- 112/2 {AI95-00296-01} This operation returns the outer product of a (column) vector Left by a (row) vector Right using the appropriate operation "*" in `numerics.generic_complex_types` for computing the individual components. The first and second index ranges of the result are `Left'Range` and `Right'Range` respectively.
- 113/2 **function** "*" (Left : Complex_Vector;
 Right : Complex_Matrix) **return** Complex_Vector;
- 114/2 {AI95-00296-01} This operation provides the standard mathematical operation for multiplication of a (row) vector Left by a matrix Right. The index range of the (row) vector result is `Right'Range(2)`. `Constraint_Error` is raised if `Left'Length` is not equal to `Right'Length(1)`. This operation involves inner products.
- 115/2 **function** "*" (Left : Complex_Matrix;
 Right : Complex_Vector) **return** Complex_Vector;
- 116/2 {AI95-00296-01} This operation provides the standard mathematical operation for multiplication of a matrix Left by a (column) vector Right. The index range of the (column) vector result is `Left'Range(1)`. `Constraint_Error` is raised if `Left'Length(2)` is not equal to `Right'Length`. This operation involves inner products.
- 117/2 **function** "+" (Left : Real_Matrix;
 Right : Complex_Matrix) **return** Complex_Matrix;
function "+" (Left : Complex_Matrix;
 Right : Real_Matrix) **return** Complex_Matrix;
function "-" (Left : Real_Matrix;
 Right : Complex_Matrix) **return** Complex_Matrix;
function "-" (Left : Complex_Matrix;
 Right : Real_Matrix) **return** Complex_Matrix;
- 118/2 {AI95-00296-01} Each operation returns the result of applying the corresponding operation in `numerics.generic_complex_types` to each component of Left and the matching component of Right. The index ranges of the result are those of Left. `Constraint_Error` is raised if `Left'Length(1)` is not equal to `Right'Length(1)` or `Left'Length(2)` is not equal to `Right'Length(2)`.
- 119/2 **function** "*" (Left : Real_Matrix;
 Right : Complex_Matrix) **return** Complex_Matrix;
function "*" (Left : Complex_Matrix;
 Right : Real_Matrix) **return** Complex_Matrix;
- 120/2 {AI95-00296-01} Each operation provides the standard mathematical operation for matrix multiplication. The first and second index ranges of the result are `Left'Range(1)` and `Right'Range(2)` respectively. `Constraint_Error` is raised if `Left'Length(2)` is not equal to `Right'Length(1)`. These operations involve inner products.

function "*" (Left : Real_Vector; Right : Complex_Vector) return Complex_Matrix;	121/2
function "*" (Left : Complex_Vector; Right : Real_Vector) return Complex_Matrix;	
{AI95-00296-01} Each operation returns the outer product of a (column) vector Left by a (row) vector Right using the appropriate operation "*" in numerics.generic_complex_types for computing the individual components. The first and second index ranges of the result are Left'Range and Right'Range respectively.	122/2
function "*" (Left : Real_Vector; Right : Complex_Matrix) return Complex_Vector;	123/2
function "*" (Left : Complex_Vector; Right : Real_Matrix) return Complex_Vector;	
{AI95-00296-01} Each operation provides the standard mathematical operation for multiplication of a (row) vector Left by a matrix Right. The index range of the (row) vector result is Right'Range(2). Constraint_Error is raised if Left'Length is not equal to Right'Length(1). These operations involve inner products.	124/2
function "*" (Left : Real_Matrix; Right : Complex_Vector) return Complex_Vector;	125/2
function "*" (Left : Complex_Matrix; Right : Real_Vector) return Complex_Vector;	
{AI95-00296-01} Each operation provides the standard mathematical operation for multiplication of a matrix Left by a (column) vector Right. The index range of the (column) vector result is Left'Range(1). Constraint_Error is raised if Left'Length(2) is not equal to Right'Length. These operations involve inner products.	126/2
function "*" (Left : Complex; Right : Complex_Matrix) return Complex_Matrix;	127/2
{AI95-00296-01} This operation returns the result of multiplying each component of Right by the complex number Left using the appropriate operation "*" in numerics.generic_complex_types. The index ranges of the result are those of Right.	128/2
function "*" (Left : Complex_Matrix; Right : Complex) return Complex_Matrix;	129/2
function "/" (Left : Complex_Matrix; Right : Complex) return Complex_Matrix;	
{AI95-00296-01} Each operation returns the result of applying the corresponding operation in numerics.generic_complex_types to each component of the matrix Left and the complex number Right. The index ranges of the result are those of Left.	130/2
function "*" (Left : Real'Base; Right : Complex_Matrix) return Complex_Matrix;	131/2
{AI95-00296-01} This operation returns the result of multiplying each component of Right by the real number Left using the appropriate operation "*" in numerics.generic_complex_types. The index ranges of the result are those of Right.	132/2
function "*" (Left : Complex_Matrix; Right : Real'Base) return Complex_Matrix;	133/2
function "/" (Left : Complex_Matrix; Right : Real'Base) return Complex_Matrix;	
{AI95-00296-01} Each operation returns the result of applying the corresponding operation in numerics.generic_complex_types to each component of the matrix Left and the real number Right. The index ranges of the result are those of Left.	134/2
function Solve (A : Complex_Matrix; X : Complex_Vector) return Complex_Vector;	135/2
{AI95-00296-01} This function returns a vector Y such that X is (nearly) equal to A * Y. This is the standard mathematical operation for solving a single set of linear equations. The index range	136/2

of the result is A'Range(2). Constraint_Error is raised if A'Length(1), A'Length(2), and X'Length are not equal. Constraint_Error is raised if the matrix A is ill-conditioned.

136.a/2 **Discussion:** The text says that Y is such that “X is (nearly) equal to A * Y” rather than “X is equal to A * Y” because rounding errors may mean that there is no value of Y such that X is exactly equal to A * Y. On the other hand it does not mean that any old rough value will do. The algorithm given under Implementation Advice should be followed.

136.b/2 The requirement to raise Constraint_Error if the matrix is ill-conditioned is really a reflection of what will happen if the matrix is ill-conditioned. See Implementation Advice. We do not make any attempt to define ill-conditioned formally.

136.c/2 These remarks apply to all versions of Solve and Inverse.

137/2 **function** Solve (A, X : Complex_Matrix) **return** Complex_Matrix;

138/2 {AI95-00296-01} This function returns a matrix Y such that X is (nearly) equal to A * Y. This is the standard mathematical operation for solving several sets of linear equations. The index ranges of the result are A'Range(2) and X'Range(2). Constraint_Error is raised if A'Length(1), A'Length(2), and X'Length(1) are not equal. Constraint_Error is raised if the matrix A is ill-conditioned.

139/2 **function** Inverse (A : Complex_Matrix) **return** Complex_Matrix;

140/2 {AI95-00296-01} This function returns a matrix B such that A * B is (nearly) equal to the unit matrix. The index ranges of the result are A'Range(2) and A'Range(1). Constraint_Error is raised if A'Length(1) is not equal to A'Length(2). Constraint_Error is raised if the matrix A is ill-conditioned.

141/2 **function** Determinant (A : Complex_Matrix) **return** Complex;

142/2 {AI95-00296-01} This function returns the determinant of the matrix A. Constraint_Error is raised if A'Length(1) is not equal to A'Length(2).

143/2 **function** Eigenvalues(A : Complex_Matrix) **return** Real_Vector;

144/2 {AI95-00296-01} This function returns the eigenvalues of the Hermitian matrix A as a vector sorted into order with the largest first. Constraint_Error is raised if A'Length(1) is not equal to A'Length(2). The index range of the result is A'Range(1). Argument_Error is raised if the matrix A is not Hermitian.

144.a/2 **Discussion:** A Hermitian matrix is one whose transpose is equal to its complex conjugate. The eigenvalues of a Hermitian matrix are always real. We only support this case because algorithms for solving the general case are inherently unstable.

145/2 **procedure** Eigensystem(A : **in** Complex_Matrix;
Values : **out** Real_Vector;
Vectors : **out** Complex_Matrix);

146/3 {AI95-00296-01} {AI05-0047-1} This procedure computes both the eigenvalues and eigenvectors of the Hermitian matrix A. The out parameter Values is the same as that obtained by calling the function Eigenvalues. The out parameter Vectors is a matrix whose columns are the eigenvectors of the matrix A. The order of the columns corresponds to the order of the eigenvalues. The eigenvectors are mutually orthonormal, including when there are repeated eigenvalues. Constraint_Error is raised if A'Length(1) is not equal to A'Length(2), or if Values'Range is not equal to A'Range(1), or if the index ranges of the parameter Vectors are not equal to those of A. Argument_Error is raised if the matrix A is not Hermitian. Constraint_Error is also raised in implementation-defined circumstances if the algorithm used does not converge quickly enough.

146.a/3 **Ramification:** {AI05-0047-1} There is no requirement on the absolute direction of the returned eigenvectors. Thus they might be multiplied by any complex number whose modulus is 1. It is only the ratios of the components that matter. This is standard practice.

```

function Unit_Matrix (Order           : Positive;
                       First_1, First_2 : Integer := 1)
                       return Complex_Matrix;

```

{AI95-00296-01} This function returns a square *unit matrix* with Order^2 components and lower bounds of `First_1` and `First_2` (for the first and second index ranges respectively). All components are set to (0.0, 0.0) except for the main diagonal, whose components are set to (1.0, 0.0). `Constraint_Error` is raised if $\text{First_1} + \text{Order} - 1 > \text{Integer}'\text{Last}$ or $\text{First_2} + \text{Order} - 1 > \text{Integer}'\text{Last}$.

Implementation Requirements

{AI95-00296-01} Accuracy requirements for the subprograms `Solve`, `Inverse`, `Determinant`, `Eigenvalues` and `Eigensystem` are implementation defined.

Implementation defined: The accuracy requirements for the subprograms `Solve`, `Inverse`, `Determinant`, `Eigenvalues` and `Eigensystem` for type `Complex_Matrix`.

{AI95-00296-01} For operations not involving an inner product, the accuracy requirements are those of the corresponding operations of the type `Real_Base` and `Complex` in both the strict mode and the relaxed mode (see G.2).

{AI95-00296-01} For operations involving an inner product, no requirements are specified in the relaxed mode. In the strict mode the modulus of the absolute error of the inner product $X*Y$ shall not exceed $g*\text{abs}(X)*\text{abs}(Y)$ where g is defined as

$g = X'\text{Length} * \text{Real}'\text{Machine_Radix}^{**}(1 - \text{Real}'\text{Model_Mantissa})$
for mixed complex and real operands

$g = \text{sqrt}(2.0) * X'\text{Length} * \text{Real}'\text{Machine_Radix}^{**}(1 - \text{Real}'\text{Model_Mantissa})$
for two complex operands

{AI95-00418-01} For the L2-norm, no accuracy requirements are specified in the relaxed mode. In the strict mode the relative error on the norm shall not exceed $g / 2.0 + 3.0 * \text{Real}'\text{Model_Epsilon}$ where g has the definition appropriate for two complex operands.

Documentation Requirements

{AI95-00296-01} Implementations shall document any techniques used to reduce cancellation errors such as extended precision arithmetic.

Documentation Requirement: Any techniques used to reduce cancellation errors in `Numerics.Generic_Complex_Arrays` shall be documented.

Implementation Note: The above accuracy requirement is met by the canonical implementation of the inner product by multiplication and addition using the corresponding operations of type `Complex` and performing the cumulative addition using ascending indices. Note however, that some hardware provides special operations for the computation of the inner product and although these may be fast they may not meet the accuracy requirement specified. See *Accuracy and Stability of Numerical Algorithms* by N J Higham (ISBN 0-89871-355-2), Sections 3.1 and 3.6.

Implementation Permissions

{AI95-00296-01} The nongeneric equivalent packages may, but need not, be actual instantiations of the generic package for the appropriate predefined type.

{AI95-00296-01} Although many operations are defined in terms of operations from `numerics.-generic_complex_types`, they need not be implemented by calling those operations provided that the effect is the same.

Implementation Advice

- 158/3 {AI95-00296-01} {AI05-0264-1} Implementations should implement the Solve and Inverse functions using established techniques. Implementations are recommended to refine the result by performing an iteration on the residuals; if this is done, then it should be documented.
- 158.a/2 **Implementation Advice:** Solve and Inverse for Numerics.Generic_Complex_Arrays should be implemented using established techniques and the result should be refined by an iteration on the residuals.
- 159/2 {AI95-00296-01} It is not the intention that any special provision should be made to determine whether a matrix is ill-conditioned or not. The naturally occurring overflow (including division by zero) which will result from executing these functions with an ill-conditioned matrix and thus raise Constraint_Error is sufficient.
- 159.a/2 **Discussion:** There isn't any advice for the implementation to document with this paragraph.
- 160/2 {AI95-00296-01} The test that a matrix is Hermitian should use the equality operator to compare the real components and negation followed by equality to compare the imaginary components (see G.2.1).
- 160.a/2 **Implementation Advice:** The equality and negation operators should be used to test that a matrix is Hermitian.
- 160.1/3 An implementation should minimize the circumstances under which the algorithm used for Eigenvalues and Eigensystem fails to converge.
- 160.a.1/3 **Implementation Advice:** An implementation should minimize the circumstances under which the algorithm used for Numerics.Generic_Complex_Arrays.Eigenvalues and Numerics.Generic_Complex_Arrays.Eigensystem fails to converge.
- 160.b/3 **Implementation Note:** J. H. Wilkinson is the acknowledged expert in this area. See for example Wilkinson, J. H., and Reinsch, C. , Linear Algebra , vol II of Handbook for Automatic Computation, Springer-Verlag, or Wilkinson, J. H., The Algebraic Eigenvalue Problem, Oxford University Press.
- 161/2 {AI95-00296-01} Implementations should not perform operations on mixed complex and real operands by first converting the real operand to complex. See G.1.1.
- 161.a/2 **Implementation Advice:** Mixed real and complex operations should not be performed by converting the real operand to complex.

Extensions to Ada 95

- 161.b/2 {AI95-00296-01} The package Numerics.Generic_Complex_Arrays and its nongeneric equivalents are new.

Wording Changes from Ada 2005

- 161.c/3 {AI05-0047-1} **Correction:** Corrected various accuracy and definition issues.

Annex H

(normative)

High Integrity Systems

{AI95-00347-01} This Annex addresses requirements for high integrity systems (including safety-critical systems and security-critical systems). It provides facilities and specifies documentation requirements that relate to several needs: 1/2

- Understanding program execution; 2
- Reviewing object code; 3
- Restricting language constructs whose usage might complicate the demonstration of program correctness 4

Execution understandability is supported by pragma `Normalize_Scalars`, and also by requirements for the implementation to document the effect of a program in the presence of a bounded error or where the language rules leave the effect unspecified. 4.1

The pragmas `Reviewable` and `Restrictions` relate to the other requirements addressed by this Annex. 5

NOTES

1 The `Valid` attribute (see 13.9.2) is also useful in addressing these needs, to avoid problems that could otherwise arise from scalars that have values outside their declared range constraints. 6

Discussion: The Annex tries to provide high assurance rather than language features. However, it is not possible, in general, to test for high assurance. For any specific language feature, it is possible to demonstrate its presence by a functional test, as in the ACVC. One can also check for the presence of some documentation requirements, but it is not easy to determine objectively that the documentation is “adequate”. 6.a

Extensions to Ada 83

This Annex is new to Ada 95. 6.b

Wording Changes from Ada 95

{AI95-00347-01} The title of this annex was changed to better reflect its purpose and scope. High integrity systems has become the standard way of identifying systems that have high reliability requirements; it subsumes terms such as safety and security. Moreover, the annex does not include any security specific features and as such the previous title is somewhat misleading. 6.c/2

H.1 Pragma `Normalize_Scalars`

This pragma ensures that an otherwise uninitialized scalar object is set to a predictable value, but out of range if possible. 1

Discussion: The goal of the pragma is to reduce the impact of a bounded error that results from a reference to an uninitialized scalar object, by having such a reference violate a range check and thus raise `Constraint_Error`. 1.a

Syntax

The form of a pragma `Normalize_Scalars` is as follows: 2

pragma `Normalize_Scalars`;
3

Post-Compilation Rules

Pragma `Normalize_Scalars` is a configuration pragma. It applies to all `compilation_units` included in a partition. 4

Documentation Requirements

- 5/2 {AI95-00434-01} If a pragma `Normalize_Scalars` applies, the implementation shall document the implicit initial values for scalar subtypes, and shall identify each case in which such a value is used and is not an invalid representation.
- 5.a/2 **Documentation Requirement:** If a pragma `Normalize_Scalars` applies, the implicit initial values of scalar subtypes shall be documented. Such a value should be an invalid representation when possible; any cases when it is not shall be documented.
- 5.b **To be honest:** It's slightly inaccurate to say that the value is a representation, but the point should be clear anyway.
- 5.c **Discussion:** By providing a type with a size specification so that spare bits are present, it is possible to force an implementation of `Normalize_Scalars` to use an out of range value. This can be tested for by ensuring that `Constraint_Error` is raised. Similarly, for an unconstrained integer type, in which no spare bit is surely present, one can check that the initialization takes place to the value specified in the documentation of the implementation. For a floating point type, spare bits might not be available, but a range constraint can provide the ability to use an out of range value.
- 5.d If it is difficult to document the general rule for the implicit initial value, the implementation might choose instead to record the value on the object code listing or similar output produced during compilation.

Implementation Advice

- 6/2 {AI95-00434-01} Whenever possible, the implicit initial values for a scalar subtype should be an invalid representation (see 13.9.1).
- 6.a **Discussion:** When an out of range value is used for the initialization, it is likely that constraint checks will detect it. In addition, it can be detected by the `Valid` attribute.
- 6.b/2 This rule is included in the documentation requirements, and thus does not need a separate summary item.

NOTES

- 7 2 The initialization requirement applies to uninitialized scalar objects that are subcomponents of composite objects, to allocated objects, and to stand-alone objects. It also applies to scalar **out** parameters. Scalar subcomponents of composite **out** parameters are initialized to the corresponding part of the actual, by virtue of 6.4.1.
- 8 3 The initialization requirement does not apply to a scalar for which pragma `Import` has been specified, since initialization of an imported object is performed solely by the foreign language environment (see B.1).
- 9 4 The use of pragma `Normalize_Scalars` in conjunction with `Pragma Restrictions(No_Exceptions)` may result in erroneous execution (see H.4).
- 9.a **Discussion:** Since the effect of an access to an out of range value will often be to raise `Constraint_Error`, it is clear that suppressing the exception mechanism could result in erroneous execution. In particular, the assignment to an array, with the array index out of range, will result in a write to an arbitrary store location, having unpredictable effects.

H.2 Documentation of Implementation Decisions*Documentation Requirements*

- 1 The implementation shall document the range of effects for each situation that the language rules identify as either a bounded error or as having an unspecified effect. If the implementation can constrain the effects of erroneous execution for a given construct, then it shall document such constraints. [The documentation might be provided either independently of any compilation unit or partition, or as part of an annotated listing for a given unit or partition. See also 1.1.3, and 1.1.2.]
- 1.a/2 *This paragraph was deleted.*
- 1.b/2 **Documentation Requirement:** The range of effects for each bounded error and each unspecified effect. If the effects of a given erroneous construct are constrained, the constraints shall be documented.

NOTES

- 2 5 Among the situations to be documented are the conventions chosen for parameter passing, the methods used for the management of run-time storage, and the method used to evaluate numeric expressions if this involves extended range or extra precision.
- 2.a **Discussion:** Look up “unspecified” and “erroneous execution” in the index for a list of the cases.

The management of run-time storage is particularly important. For safety applications, it is often necessary to show that a program cannot raise `Storage_Error`, and for security applications that information cannot leak via the run-time system. Users are likely to prefer a simple storage model that can be easily validated. 2.b

The documentation could helpfully take into account that users may well adopt a subset to avoid some forms of erroneous execution, for instance, not using the abort statement, so that the effects of a partly completed `assignment_statement` do not have to be considered in the validation of a program (see 9.8). For this reason documentation linked to an actual compilation may be most useful. Similarly, an implementation may be able to take into account use of the Restrictions pragma. 2.c

H.3 Reviewable Object Code

Object code review and validation are supported by pragmas `Reviewable` and `Inspection_Point`. 1

H.3.1 Pragma `Reviewable`

This pragma directs the implementation to provide information to facilitate analysis and review of a program's object code, in particular to allow determination of execution time and storage usage and to identify the correspondence between the source and object programs. 1

Discussion: Since the purpose of this pragma is to provide information to the user, it is hard to objectively test for conformity. In practice, users want the information in an easily understood and convenient form, but neither of these properties can be easily measured. 1.a

Syntax

The form of a pragma `Reviewable` is as follows: 2

pragma `Reviewable`; 3

Post-Compilation Rules

Pragma `Reviewable` is a configuration pragma. It applies to all `compilation_units` included in a partition. 4

Implementation Requirements

The implementation shall provide the following information for any compilation unit to which such a pragma applies: 5

Discussion: The list of requirements can be checked for, even if issues like intelligibility are not addressed. 5.a

- Where compiler-generated run-time checks remain; 6

Discussion: A constraint check which is implemented via a check on the upper and lower bound should clearly be indicated. If a check is implicit in the form of machine instructions used (such as overflow checking), this should also be covered by the documentation. It is particularly important to cover those checks which are not obvious from the source code, such as that for stack overflow. 6.a

- An identification of any construct with a language-defined check that is recognized prior to run time as certain to fail if executed (even if the generation of run-time checks has been suppressed); 7

Discussion: In this case, if the compiler determines that a check must fail, the user should be informed of this. However, since it is not in general possible to know what the compiler will detect, it is not easy to test for this. In practice, it is thought that compilers claiming conformity to this Annex will perform significant optimizations and therefore *will* detect such situations. Of course, such events could well indicate a programmer error. 7.a

- `{AI95-00209-01}` For each read of a scalar object, an identification of the read as either “known to be initialized,” or “possibly uninitialized,” independent of whether pragma `Normalize_Scalars` applies; 8/2

Discussion: This issue again raises the question as to what the compiler has determined. A lazy implementation could clearly mark all scalars as “possibly uninitialized”, but this would be very unhelpful to the user. It should be possible to analyze a range of scalar uses and note the percentage in each class. Note that an access marked “known to be initialized” does not imply that the value is in range, since the initialization could be from an (erroneous) call of unchecked conversion, or by means external to the Ada program. 8.a

- 9 • Where run-time support routines are implicitly invoked;
 - 9.a **Discussion:** Validators will need to know the calls invoked in order to check for the correct functionality. For instance, for some safety applications, it may be necessary to ensure that certain sections of code can execute in a particular time.
 - 10 • An object code listing, including:
 - 11 • Machine instructions, with relative offsets;
 - 11.a **Discussion:** The machine instructions should be in a format that is easily understood, such as the symbolic format of the assembler. The relative offsets are needed in numeric format, to check any alignment restrictions that the architecture might impose.
 - 12 • Where each data object is stored during its lifetime;
 - 12.a **Discussion:** This requirement implies that if the optimizer assigns a variable to a register, this needs to be evident.
 - 13 • Correspondence with the source program, including an identification of the code produced per declaration and per statement.
 - 13.a **Discussion:** This correspondence will be quite complex when extensive optimization is performed. In particular, address calculation to access some data structures could be moved from the actual access. However, when all the machine code arising from a statement or declaration is in one basic block, this must be indicated by the implementation.
 - 14 • An identification of each construct for which the implementation detects the possibility of erroneous execution;
 - 14.a **Discussion:** This requirement is quite vague. In general, it is hard for compilers to detect erroneous execution and therefore the requirement will be rarely invoked. However, if the pragma Suppress is used and the compiler can show that a predefined exception will be raised, then such an identification would be useful.
 - 15 • For each subprogram, block, task, or other construct implemented by reserving and subsequently freeing an area on a run-time stack, an identification of the length of the fixed-size portion of the area and an indication of whether the non-fixed size portion is reserved on the stack or in a dynamically-managed storage region.
 - 15.a **Discussion:** This requirement is vital for those requiring to show that the storage available to a program is sufficient. This is crucial in those cases in which the internal checks for stack overflow are suppressed (perhaps by **pragma Restrictions(No_Exceptions)**).
- 16 The implementation shall provide the following information for any partition to which the pragma applies:
- 17 • An object code listing of the entire partition, including initialization and finalization code as well as run-time system components, and with an identification of those instructions and data that will be relocated at load time;
 - 17.a **Discussion:** The object code listing should enable a validator to estimate upper bounds for the time taken by critical parts of a program. Similarly, by an analysis of the entire partition, it should be possible to ensure that the storage requirements are suitably bounded, assuming that the partition was written in an appropriate manner.
 - 18 • A description of the run-time model relevant to the partition.
 - 18.a **Discussion:** For example, a description of the storage model is vital, since the Ada language does not explicitly define such a model.
- 18.1 The implementation shall provide control- and data-flow information, both within each compilation unit and across the compilation units of the partition.
- 18.b **Discussion:** This requirement is quite vague, since it is unclear what control and data flow information the compiler has produced. It is really a plea not to throw away information that could be useful to the validator. Note that the data flow information is relevant to the detection of “possibly uninitialized” objects referred to above.

Implementation Advice

- 19 The implementation should provide the above information in both a human-readable and machine-readable form, and should document the latter so as to ease further processing by automated tools.

Implementation Advice: The information produced by pragma Reviewable should be provided in both a human-readable and machine-readable form, and the latter form should be documented.	19.a/2
Object code listings should be provided both in a symbolic format and also in an appropriate numeric format (such as hexadecimal or octal).	20
Implementation Advice: Object code listings should be provided both in a symbolic format and in a numeric format.	20.a/2
Reason: This is to enable other tools to perform any analysis that the user needed to aid validation. The format should be in some agreed form.	20.b
NOTES	
6 The order of elaboration of library units will be documented even in the absence of pragma Reviewable (see 10.2).	21
Discussion: There might be some interactions between pragma Reviewable and compiler optimizations. For example, an implementation may disable some optimizations when pragma Reviewable is in force if it would be overly complicated to provide the detailed information to allow review of the optimized object code. See also pragma Optimize (2.8).	21.a
<i>Wording Changes from Ada 95</i>	
{AI95-00209-01} The wording was clarified that pragma Reviewable applies to each read of an object, as it makes no sense to talk about the state of an object that will immediately be overwritten.	21.b/2

H.3.2 Pragma Inspection_Point

An occurrence of a pragma Inspection_Point identifies a set of objects each of whose values is to be available at the point(s) during program execution corresponding to the position of the pragma in the compilation unit. The purpose of such a pragma is to facilitate code validation.	1
Discussion: Inspection points are a high level equivalent of break points used by debuggers.	1.a
<i>Syntax</i>	
The form of a pragma Inspection_Point is as follows:	2
pragma Inspection_Point[(<i>object_name</i> {, <i>object_name</i> })];	3
<i>Legality Rules</i>	
A pragma Inspection_Point is allowed wherever a declarative_item or statement is allowed. Each <i>object_name</i> shall statically denote the declaration of an object.	4
Discussion: The static denotation is required, since no dynamic evaluation of a name is involved in this pragma.	4.a
<i>Static Semantics</i>	
{8652/0093} {AI95-00207-01} {AI95-00434-01} An <i>inspection point</i> is a point in the object code corresponding to the occurrence of a pragma Inspection_Point in the compilation unit. An object is <i>inspectable</i> at an inspection point if the corresponding pragma Inspection_Point either has an argument denoting that object, or has no arguments and the declaration of the object is visible at the inspection point.	5/2
Ramification: If a pragma Inspection_Point is in an in-lined subprogram, there might be numerous inspection points in the object code corresponding to the single occurrence of the pragma in the source; similar considerations apply if such a pragma is in a generic, or in a loop that has been “unrolled” by an optimizer.	5.a
{8652/0093} {AI95-00207-01} The short form of the pragma is a convenient shorthand for listing all objects which could be explicitly made inspectable by the long form of the pragma; thus only visible objects are made inspectable by it. Objects that are not visible at the point of the pragma are not made inspectable by the short form pragma. This is necessary so that implementations need not keep information about (or prevent optimizations on) a unit simply because some other unit <i>might</i> contain a short form Inspection_Point pragma.	5.a.1/1
Discussion: {8652/0093} {AI95-00207-01} If the short form of the pragma is used, then all visible objects are inspectable. This implies that global objects from other compilation units are inspectable. A good interactive debugging system could provide information similar to a post-mortem dump at such inspection points. The annex does	5.b/1

not require that any inspection facility is provided, merely that the information is available to understand the state of the machine at those points.

Dynamic Semantics

6 Execution of a pragma `Inspection_Point` has no effect.

6.a/2 **Discussion:** {AI95-00114-01} Although an inspection point has no (semantic) effect, the removal or adding of a new point could change the machine code generated by the compiler.

Implementation Requirements

7 Reaching an inspection point is an external interaction with respect to the values of the inspectable objects at that point (see 1.1.3).

7.a **Ramification:** The compiler is inhibited from moving an assignment to an inspectable variable past an inspection point for that variable. On the other hand, the evaluation of an expression that might raise an exception may be moved past an inspection point (see 11.6).

Documentation Requirements

8 For each inspection point, the implementation shall identify a mapping between each inspectable object and the machine resources (such as memory locations or registers) from which the object's value can be obtained.

8.a/2 *This paragraph was deleted.*

8.b/2 **Documentation Requirement:** For each inspection point, a mapping between each inspectable object and the machine resources where the object's value can be obtained shall be provided.

NOTES

9/2 7 {AI95-00209-01} The implementation is not allowed to perform “dead store elimination” on the last assignment to a variable prior to a point where the variable is inspectable. Thus an inspection point has the effect of an implicit read of each of its inspectable objects.

10 8 Inspection points are useful in maintaining a correspondence between the state of the program in source code terms, and the machine state during the program's execution. Assertions about the values of program objects can be tested in machine terms at inspection points. Object code between inspection points can be processed by automated tools to verify programs mechanically.

10.a **Discussion:** Although it is not a requirement of the annex, it would be useful if the state of the stack and heap could be interrogated. This would allow users to check that a program did not have a ‘storage leak’.

11 9 The identification of the mapping from source program objects to machine resources is allowed to be in the form of an annotated object listing, in human-readable or tool-processable form.

11.a **Discussion:** In principle, it is easy to check an implementation for this pragma, since one merely needs to check the content of objects against those values known from the source listing. In practice, one needs a tool similar to an interactive debugger to perform the check.

Wording Changes from Ada 95

11.b/2 {8652/0093} {AI95-00207-01} **Corrigendum:** Corrected the definition of the `Inspection_Point` pragma to apply to only variables visible at the point of the pragma. Otherwise, the compiler would have to assume that some other code somewhere could have a pragma `Inspection_Point`, preventing many optimizations (such as unused object elimination).

H.4 High Integrity Restrictions

1/3 {AI05-0299-1} This subclause defines restrictions that can be used with pragma Restrictions (see 13.12); these facilitate the demonstration of program correctness by allowing tailored versions of the run-time system.

1.a/3 **Discussion:** {AI05-0005-1} Note that the restrictions are absolute. If a partition has 100 library units and just one needs `Unchecked_Conversion`, then the pragma cannot be used to ensure the other 99 units do not use `Unchecked_Conversion`. Note also that these are restrictions on all Ada code within a partition, and therefore it might not be evident from the specification of a package whether a restriction can be imposed.

Static Semantics

<i>This paragraph was deleted.</i> {AI95-00347-01} {AI95-00394-01}	2/2
{AI95-00394-01} The following <i>restriction_identifiers</i> are language defined:	3/2
Tasking-related restriction:	4
No_Protected_Types	5
There are no declarations of protected types or protected objects.	
Memory-management related restrictions:	6
No_Allocators	7
There are no occurrences of an allocator.	
{8652/0042} {AI95-00130} No_Local_Allocators	8/1
Allocators are prohibited in subprograms, generic subprograms, tasks, and entry bodies.	
Ramification: Thus allocators are permitted only in expressions whose evaluation can only be performed before the main subprogram is invoked.	8.a
<i>This paragraph was deleted.</i> {8652/0042} {AI95-00130}	8.b/1
{AI05-0152-1} {AI05-0262-1} No_Anonymous_Allocators	8.1/3
There are no allocators of anonymous access types.	
{AI05-0190-1} No_Coextensions	8.2/3
There are no coextensions. See 3.10.2.	
{AI05-0190-1} No_Access_Parameter_Allocators	8.3/3
Allocators are not permitted as the actual parameter to an access parameter. See 6.1.	
<i>This paragraph was deleted.</i> {AI95-00394-01}	9/2
Immediate_Reclamation	10
Except for storage occupied by objects created by allocators and not deallocated via unchecked deallocation, any storage reserved at run time for an object is immediately reclaimed when the object no longer exists.	
Discussion: Immediate reclamation would apply to storage created by the compiler, such as for a return value from a function whose size is not known at the call site.	10.a
Exception-related restriction:	11
No_Exceptions	12
Raise_statements and exception_handlers are not allowed. No language-defined run-time checks are generated; however, a run-time check performed automatically by the hardware is permitted.	
Discussion: This restriction mirrors a method of working that is quite common in the safety area. The programmer is required to show that exceptions cannot be raised. Then a simplified run-time system is used without exception handling. However, some hardware checks may still be enforced. If the software check would have failed, or if the hardware check actually fails, then the execution of the program is unpredictable. There are obvious dangers in this approach, but it is similar to programming at the assembler level.	12.a
Other restrictions:	13
No_Floating_Point	14
Uses of predefined floating point types and operations, and declarations of new floating point types, are not allowed.	
Discussion: {AI95-00114-01} The intention is to avoid the use of floating point hardware at run time, but this is expressed in language terms. It is conceivable that floating point is used implicitly in some contexts, say fixed point type conversions of high accuracy. However, the Implementation Requirements below make it clear that the restriction would apply to the “run-time system” and hence not be allowed. This restriction could be used to inform a compiler that a variant of the architecture is being used which does not have floating point instructions.	14.a/2

- 15 **No_Fixed_Point**
 Uses of predefined fixed point types and operations, and declarations of new fixed point types, are not allowed.
- 15.a **Discussion:** This restriction would have the side effect of prohibiting the `delay_relative_statement`. As with the `No_Floating_Point` restriction, this might be used to avoid any question of rounding errors. Unless an Ada run-time is written in Ada, it seems hard to rule out implicit use of fixed point, since at the machine level, fixed point is virtually the same as integer arithmetic.
- 16/2 *This paragraph was deleted. {AI95-00394-01}*
- 17 **No_Access_Subprograms**
 The declaration of access-to-subprogram types is not allowed.
- 17.a.1/2 **Discussion:** Most critical applications would require some restrictions or additional validation checks on uses of access-to-subprogram types. If the application does not require the functionality, then this restriction provides a means of ensuring the design requirement has been satisfied. The same applies to several of the following restrictions, and to restriction `No_Dependence => Ada.Unchecked_Conversion`.
- 18 **No_Unchecked_Access**
 The `Unchecked_Access` attribute is not allowed.
- 19 **No_Dispatch**
 Occurrences of `T'Class` are not allowed, for any (tagged) subtype `T`.
- 20/2 *{AI95-00285-01}* **No_IO**
 Semantic dependence on any of the library units `Sequential_IO`, `Direct_IO`, `Text_IO`, `Wide_Text_IO`, `Wide_Wide_Text_IO`, or `Stream_IO` is not allowed.
- 20.a **Discussion:** Excluding the input-output facilities of an implementation may be needed in those environments which cannot support the supplied functionality. A program in such an environment is likely to require some low level facilities or a call on a non-Ada feature.
- 21 **No_Delay** `Delay_Statements` and semantic dependence on package `Calendar` are not allowed.
- 21.a **Ramification:** This implies that `delay_alternatives` in a `select_statement` are prohibited.
- 21.b The purpose of this restriction is to avoid the need for timing facilities within the run-time system.
- 22 **No_Recursion**
 As part of the execution of a subprogram, the same subprogram is not invoked.
- 23 **No_Reentrancy**
 During the execution of a subprogram by a task, no other task invokes the same subprogram.

Implementation Requirements

- 23.1/2 *{AI95-00394-01}* An implementation of this Annex shall support:
- 23.2/2 • the restrictions defined in this subclause; and
- 23.3/3 • *{AI05-0189-1}* the following restrictions defined in D.7: `No_Task_Hierarchy`, `No_Abort_Statement`, `No_Implicit_Heap_Allocation`, `No_Standard_Allocators_After_Elaboration`; and
- 23.4/2 • *{AI95-00347-01}* the **pragma** `Profile(Ravenscar)`; and
- 23.a/2 **Discussion:** *{AI95-00347-01}* The reference to `pragma Profile(Ravenscar)` is intended to show that properly restricted tasking is appropriate for use in high integrity systems. The Ada 95 Annex seemed to suggest that tasking was inappropriate for such systems.
- 23.5/2 • the following uses of *restriction_parameter_identifiers* defined in D.7[, which are checked prior to program execution]:
- 23.6/2 • `Max_Task_Entries => 0`,
- 23.7/2 • `Max_Asynchronous_Select_Nesting => 0`, and
- 23.8/2 • `Max_Tasks => 0`.

- {AI05-0263-1} {AI05-0272-1} If an implementation supports pragma Restrictions for a particular argument, then except for the restrictions No_Unchecked_Deallocation, No_Unchecked_Conversion, No_Access_Subprograms, No_Unchecked_Access, No_Specification_of_Aspect, No_Use_of_Attribute, No_Use_of_Pragma, and the equivalent use of No_Dependence, the associated restriction applies to the run-time system. 24/3
- Reason:** Permission is granted for the run-time system to use the specified otherwise-restricted features, since the use of these features may simplify the run-time system by allowing more of it to be written in Ada. 24.a
- Discussion:** The restrictions that are applied to the partition are also applied to the run-time system. For example, if No_Floating_Point is specified, then an implementation that uses floating point for implementing the delay statement (say) would require that No_Floating_Point is only used in conjunction with No_Delay. It is clearly important that restrictions are effective so that Max_Tasks=0 does imply that tasking is not used, even implicitly (for input-output, say). 24.b
- An implementation of tasking could be produced based upon a run-time system written in Ada in which the rendezvous was controlled by protected types. In this case, No_Protected_Types could only be used in conjunction with Max_Task_Entries=0. Other implementation dependencies could be envisaged. 24.c
- If the run-time system is not written in Ada, then the wording needs to be applied in an appropriate fashion. 24.d
- {AI05-0263-1} "the equivalent use of No_Dependence" refers to No_Dependence => Ada.Unchecked_Conversion and the like, not all uses of No_Dependence. 24.e/3

Documentation Requirements

- If a pragma Restrictions(No_Exceptions) is specified, the implementation shall document the effects of all constructs where language-defined checks are still performed automatically (for example, an overflow check performed by the processor). 25
- This paragraph was deleted.* 25.a/2
- Documentation Requirement:** If a pragma Restrictions(No_Exceptions) is specified, the effects of all constructs where language-defined checks are still performed. 25.b/2
- Discussion:** {AI95-00114-01} The documentation requirements here are quite difficult to satisfy. One method is to review the object code generated and determine the checks that are still present, either explicitly, or implicitly within the architecture. As another example from that of overflow, consider the question of dereferencing a null pointer. This could be undertaken by a memory access trap when checks are performed. When checks are suppressed via the argument No_Exceptions, it would not be necessary to have the memory access trap mechanism enabled. 25.c/2

Erroneous Execution

- Program execution is erroneous if pragma Restrictions(No_Exceptions) has been specified and the conditions arise under which a generated language-defined run-time check would fail. 26
- Discussion:** The situation here is very similar to the application of pragma Suppress. Since users are removing some of the protection the language provides, they had better be careful! 26.a
- Program execution is erroneous if pragma Restrictions(No_Recursion) has been specified and a subprogram is invoked as part of its own execution, or if pragma Restrictions(No_Reentrancy) has been specified and during the execution of a subprogram by a task, another task invokes the same subprogram. 27
- Discussion:** {AI05-0005-1} In practice, many implementations might not exploit the absence of recursion or need for reentrancy, in which case the program execution would be unaffected by the use of recursion or reentrancy, even though the program is still formally erroneous. 27.a/3
- This paragraph was deleted.* 27.b/2
- NOTES
- 10 {AI95-00394-01} Uses of *restriction_parameter_identifier* No_Dependence defined in 13.12.1: No_Dependence => Ada.Unchecked_Deallocation and No_Dependence => Ada.Unchecked_Conversion may be appropriate for high-integrity systems. Other uses of No_Dependence can also be appropriate for high-integrity systems. 28/2
- Discussion:** The specific mention of these two uses is meant to replace the identifiers now banished to J.13, "Dependence Restriction Identifiers". 28.a/2

- 28.b/2 Restriction `No_Dependence => Ada.Unchecked_Deallocation` would be useful in those contexts in which heap storage is needed on program start-up, but need not be increased subsequently. The danger of a dangling pointer can therefore be avoided.

Extensions to Ada 95

- 28.c/2 {8652/0042} {AI95-00130-01} `No_Local_Allocators` no longer prohibits generic instantiations.

Wording Changes from Ada 95

- 28.d/2 {AI95-00285-01} `Wide_Wide_Text_IO` (which is new) is added to the `No_IO` restriction.
- 28.e/3 {AI95-00347-01} {AI05-0299-1} The title of this subclause was changed to match the change to the Annex title. `Pragma_Profile(Ravenscar)` is part of this annex.
- 28.f/2 {AI95-00394-01} Restriction `No_Dependence` is used instead of special *restriction_identifiers*. The old names are banished to *Obsolescent Features* (see J.13).
- 28.g/2 {AI95-00394-01} The bizarre wording “apply in this Annex” (which no one quite can explain the meaning of) is banished.

Extensions to Ada 2005

- 28.h/3 {AI05-0152-1} {AI05-0190-1} Restrictions `No_Anonymous_Allocators`, `No_Coextensions`, and `No_Access_Parameter_Allocators` are new.

Wording Changes from Ada 2005

- 28.i/3 {AI05-0189-1} New restriction `No_Standard_Allocators_After_Elaboration` is added to the list of restrictions that are required by this annex.
- 28.j/3 {AI05-0263-1} **Correction:** Ada 2005 restriction `No_Dependence` is added where needed (this was missed in Ada 2005).
- 28.k/3 {AI05-0272-1} Restrictions against individual aspects, pragmas, and attributes do not apply to the run-time system, in order that an implementation can use whatever aspects, pragmas, and attributes are needed to do the job. For instance, attempting to write a run-time system for Linux that does not use the `Import` aspect would be very difficult and probably is not what the user is trying to prevent anyway.

H.5 Pragma Detect_Blocking

- 1/2 {AI95-00305-01} The following pragma forces an implementation to detect potentially blocking operations within a protected operation.

Syntax

- 2/2 {AI95-00305-01} The form of a `pragma Detect_Blocking` is as follows:
- 3/2 **pragma** `Detect_Blocking`;

Post-Compilation Rules

- 4/2 {AI95-00305-01} A `pragma Detect_Blocking` is a configuration pragma.

Dynamic Semantics

- 5/2 {AI95-00305-01} An implementation is required to detect a potentially blocking operation within a protected operation, and to raise `Program_Error` (see 9.5.1).

Implementation Permissions

- 6/2 {AI95-00305-01} An implementation is allowed to reject a `compilation_unit` if a potentially blocking operation is present directly within an `entry_body` or the body of a protected subprogram.

NOTES

- 7/2 11 {AI95-00305-01} An operation that causes a task to be blocked within a foreign language domain is not defined to be potentially blocking, and need not be detected.

Extensions to Ada 95

{AI95-00305-01} Pragma Detect_Blocking is new.

7.a/2

H.6 Pragma Partition_Elaboration_Policy

{AI95-00265-01} {AI05-0299-1} This subclause defines a pragma for user control over elaboration policy. 1/3

Syntax

{AI95-00265-01} The form of a pragma Partition_Elaboration_Policy is as follows: 2/2

pragma Partition_Elaboration_Policy (*policy_identifier*); 3/2

The *policy_identifier* shall be either Sequential, Concurrent or an implementation-defined identifier. 4/2

Implementation defined: Implementation-defined *policy_identifiers* allowed in a pragma Partition_Elaboration_Policy. 4.a/2

Ramification: Note that the Ravenscar profile (see D.13) has nothing to say about which Partition_Elaboration_Policy is used. This was intentionally omitted from the profile, as there was no agreement as to whether the Sequential policy should be required for Ravenscar programs. As such it was defined separately. 4.b/3

Post-Compilation Rules

{AI95-00265-01} A pragma Partition_Elaboration_Policy is a configuration pragma. It specifies the elaboration policy for a partition. At most one elaboration policy shall be specified for a partition. 5/2

{AI95-00265-01} {AI05-0264-1} If the Sequential policy is specified for a partition, then pragma Restrictions (No_Task_Hierarchy) shall also be specified for the partition. 6/3

Dynamic Semantics

{AI95-00265-01} Notwithstanding what this International Standard says elsewhere, this pragma allows partition elaboration rules concerning task activation and interrupt attachment to be changed. If the *policy_identifier* is Concurrent, or if there is no pragma Partition_Elaboration_Policy defined for the partition, then the rules defined elsewhere in this Standard apply. 7/2

{AI95-00265-01} {AI95-00421-01} If the partition elaboration policy is Sequential, then task activation and interrupt attachment are performed in the following sequence of steps: 8/2

- The activation of all library-level tasks and the attachment of interrupt handlers are deferred until all library units are elaborated. 9/2
- The interrupt handlers are attached by the environment task. 10/2
- The environment task is suspended while the library-level tasks are activated. 11/2
- The environment task executes the main subprogram (if any) concurrently with these executing tasks. 12/2

{AI95-00265-01} {AI95-00421-01} If several dynamic interrupt handler attachments for the same interrupt are deferred, then the most recent call of Attach_Handler or Exchange_Handler determines which handler is attached. 13/2

{AI95-00265-01} {AI95-00421-01} If any deferred task activation fails, Tasking_Error is raised at the beginning of the sequence of statements of the body of the environment task prior to calling the main subprogram. 14/2

Implementation Advice

15/3 {AI95-00265-01} {AI05-0264-1} If the partition elaboration policy is Sequential and the Environment task becomes permanently blocked during elaboration, then the partition is deadlocked and it is recommended that the partition be immediately terminated.

15.a/3 **Implementation Advice:** If the partition elaboration policy is Sequential and the Environment task becomes permanently blocked during elaboration, then the partition should be immediately terminated.

Implementation Permissions

16/3 {AI95-00265-01} {AI05-0264-1} If the partition elaboration policy is Sequential and any task activation fails, then an implementation may immediately terminate the active partition to mitigate the hazard posed by continuing to execute with a subset of the tasks being active.

NOTES

17/2 12 {AI95-00421-01} If any deferred task activation fails, the environment task is unable to handle the Tasking_Error exception and completes immediately. By contrast, if the partition elaboration policy is Concurrent, then this exception could be handled within a library unit.

Extensions to Ada 95

17.a/2 {AI95-00265-01} {AI95-00421-01} Pragma Partition_Elaboration_Policy is new.

Annex J

(normative)

Obsolescent Features

{AI95-00368-01} [This Annex contains descriptions of features of the language whose functionality is largely redundant with other features defined by this International Standard. Use of these features is not recommended in newly written programs. Use of these features can be prevented by using pragma Restrictions (No_Obsolescent_Features), see 13.12.1.] 1/2

Ramification: These features are still part of the language, and have to be implemented by conforming implementations. The primary reason for putting these descriptions here is to get redundant features out of the way of most readers. The designers of the next version of Ada will have to assess whether or not it makes sense to drop these features from the language. 1.a

Wording Changes from Ada 83

The following features have been removed from the language, rather than declared to be obsolescent: 1.b

- The package Low_Level_IO (see A.6). 1.c
- The Epsilon, Mantissa, Emax, Small, Large, Safe_Emax, Safe_Small, and Safe_Large attributes of floating point types (see A.5.3). 1.d
- *This paragraph was deleted.* {AI95-00284-02} 1.e/2
- The pragmas System_Name, Storage_Unit, and Memory_Size (see 13.7). 1.f
- The pragma Shared (see C.6). 1.g

Implementations can continue to support the above features for upward compatibility. 1.h

Wording Changes from Ada 95

{AI95-00368-01} A mention of the No_Obsolescent_Features restriction was added. 1.i/2

Wording Changes from Ada 2005

{AI05-0229-1} Pragma Controlled has been removed from the language, rather than declared to be obsolescent. No existing implementation gives it any effect. An implementation could continue to support the pragma as an implementation-defined pragma for upward compatibility. 1.j/3

J.1 Renamings of Library Units

Static Semantics

The following library_unit_renaming_declarations exist: 1

```

with Ada.Unchecked_Conversion; 2
generic function Unchecked_Conversion renames Ada.Unchecked_Conversion;
with Ada.Unchecked_Deallocation; 3
generic procedure Unchecked_Deallocation renames Ada.Unchecked_Deallocation;
with Ada.Sequential_IO; 4
generic package Sequential_IO renames Ada.Sequential_IO;
with Ada.Direct_IO; 5
generic package Direct_IO renames Ada.Direct_IO;
with Ada.Text_IO; 6
package Text_IO renames Ada.Text_IO;
with Ada.IO_Exceptions; 7
package IO_Exceptions renames Ada.IO_Exceptions;
with Ada.Calendar; 8
package Calendar renames Ada.Calendar;

```

9 **with** System.Machine_Code;
 package Machine_Code **renames** System.Machine_Code; -- *If supported.*

9.a/3 **Discussion:** {A105-0004-1} These library units correspond to those declared in Ada 83, which did not have the child unit concept or the parent package Ada.

Implementation Requirements

10 The implementation shall allow the user to replace these renamings.

J.2 Allowed Replacements of Characters

Syntax

1 The following replacements are allowed for the vertical line, number sign, and quotation mark characters:

- 2 • A vertical line character (|) can be replaced by an exclamation mark (!) where used as a delimiter.
- 3 • The number sign characters (#) of a **based_literal** can be replaced by colons (:) provided that the replacement is done for both occurrences.

3.a/2 **To be honest:** {A195-00285-01} The intent is that such a replacement works in the Value, Wide_Value, and Wide_Wide_Value attributes, and in the Get procedures of Text_IO (and Wide_Text_IO and Wide_Wide_Text_IO as well)}, so that things like “16:123:” is acceptable.

- 4 • The quotation marks (") used as string brackets at both ends of a string literal can be replaced by percent signs (%) provided that the enclosed sequence of characters contains no quotation mark, and provided that both string brackets are replaced. Any percent sign within the sequence of characters shall then be doubled and each such doubled percent sign is interpreted as a single percent sign character value.

5 These replacements do not change the meaning of the program.

5.a **Reason:** The original purpose of this feature was to support hardware (for example, teletype machines) that has long been obsolete. The feature is no longer necessary for that reason. Another use of the feature has been to replace the vertical line character (|) when using certain hardware that treats that character as a (non-English) letter. The feature is no longer necessary for that reason, either, since Ada 95 has full support for international character sets. Therefore, we believe this feature is no longer necessary.

5.b Users of equipment that still uses | to represent a letter will continue to do so. Perhaps by next the time Ada is revised, such equipment will no longer be in use.

5.c Note that it was never legal to use this feature as a convenient method of including double quotes in a string without doubling them — the string literal:

5.d %*"This is quoted."*%

5.e/3 {A105-0248-1} is not legal in Ada (and never was legal). One has to write:

5.f *"""This is quoted."""*

J.3 Reduced Accuracy Subtypes

1 A **digits_constraint** may be used to define a floating point subtype with a new value for its requested decimal precision, as reflected by its **Digits** attribute. Similarly, a **delta_constraint** may be used to define an ordinary fixed point subtype with a new value for its **delta**, as reflected by its **Delta** attribute.

1.a **Discussion:** It might be more direct to make these attributes specifiable via an **attribute_definition_clause**, and eliminate the syntax for these **_constraints**.

Syntax

2 **delta_constraint** ::= **delta** *static_expression* [**range_constraint**]

Name Resolution Rules

The expression of a `delta_constraint` is expected to be of any real type. 3

Legality Rules

The expression of a `delta_constraint` shall be static. 4

For a `subtype_indication` with a `delta_constraint`, the `subtype_mark` shall denote an ordinary fixed point subtype. 5

For a `subtype_indication` with a `digits_constraint`, the `subtype_mark` shall denote either a decimal fixed point subtype or a floating point subtype (notwithstanding the rule given in 3.5.9 that only allows a decimal fixed point subtype). 6

This paragraph was deleted. {A195-00114-01} 6.a/2

Static Semantics

A `subtype_indication` with a `subtype_mark` that denotes an ordinary fixed point subtype and a `delta_constraint` defines an ordinary fixed point subtype with a *delta* given by the value of the expression of the `delta_constraint`. If the `delta_constraint` includes a `range_constraint`, then the ordinary fixed point subtype is constrained by the `range_constraint`. 7

A `subtype_indication` with a `subtype_mark` that denotes a floating point subtype and a `digits_constraint` defines a floating point subtype with a requested decimal precision (as reflected by its `Digits` attribute) given by the value of the expression of the `digits_constraint`. If the `digits_constraint` includes a `range_constraint`, then the floating point subtype is constrained by the `range_constraint`. 8

Dynamic Semantics

A `delta_constraint` is *compatible* with an ordinary fixed point subtype if the value of the expression is no less than the *delta* of the subtype, and the `range_constraint`, if any, is compatible with the subtype. 9

A `digits_constraint` is *compatible* with a floating point subtype if the value of the expression is no greater than the requested decimal precision of the subtype, and the `range_constraint`, if any, is compatible with the subtype. 10

The elaboration of a `delta_constraint` consists of the elaboration of the `range_constraint`, if any. 11

Reason: A numeric subtype is considered “constrained” only if a range constraint applies to it. The only effect of a `digits_constraint` or a `delta_constraint` without a `range_constraint` is to specify the value of the corresponding `Digits` or `Delta` attribute in the new subtype. The set of values of the subtype is not “constrained” in any way by such constraints. 11.a

Wording Changes from Ada 83

In Ada 83, a `delta_constraint` is called a `fixed_point_constraint`, and a `digits_constraint` is called a `floating_point_constraint`. We have adopted other terms because `digits_constraints` apply primarily to decimal fixed point types now (they apply to floating point types only as an obsolescent feature). 11.b

J.4 The Constrained Attribute

Static Semantics

For every private subtype `S`, the following attribute is defined: 1

Discussion: This includes generic formal private subtypes. 1.a

`S'Constrained` 2

Yields the value `False` if `S` denotes an unconstrained nonformal private subtype with discriminants; also yields the value `False` if `S` denotes a generic formal private subtype, and

the associated actual subtype is either an unconstrained subtype with discriminants or an unconstrained array subtype; yields the value True otherwise. The value of this attribute is of the predefined subtype Boolean.

- 2.a **Reason:** Because Ada 95 has `unknown_discriminant_parts`, the `Constrained` attribute of private subtypes is obsolete. This is fortunate, since its Ada 83 definition was confusing, as explained below. Because this attribute is obsolete, we do not bother to extend its definition to private extensions.
- 2.b The `Constrained` attribute of an object is *not* obsolete.
- 2.c Note well: `S'Constrained` matches the Ada 95 definition of “constrained” only for composite subtypes. For elementary subtypes, `S'Constrained` is always true, whether or not S is constrained. (The `Constrained` attribute of an object does not have this problem, as it is only defined for objects of a discriminated type.) So one should think of its designator as being `'Constrained_Or_Elementary`.

J.5 ASCII

Static Semantics

1 The following declaration exists in the declaration of package `Standard`:

```

2  package ASCII is
3      -- Control characters:
4      NUL    : constant Character := nul;    SOH    : constant Character := soh;
5      STX    : constant Character := stx;    ETX    : constant Character := etx;
6      EOT    : constant Character := eot;    ENQ    : constant Character := enq;
7      ACK    : constant Character := ack;    BEL    : constant Character := bel;
8      BS     : constant Character := bs;    HT     : constant Character := ht;
9      LF     : constant Character := lf;    VT     : constant Character := vt;
10     FF     : constant Character := ff;    CR     : constant Character := cr;
11     SO     : constant Character := so;    SI     : constant Character := si;
12     DLE    : constant Character := dle;    DC1    : constant Character := dc1;
13     DC2    : constant Character := dc2;    DC3    : constant Character := dc3;
14     DC4    : constant Character := dc4;    NAK    : constant Character := nak;
15     SYN    : constant Character := syn;    ETB    : constant Character := etb;
16     CAN    : constant Character := can;    EM     : constant Character := em;
17     SUB    : constant Character := sub;    ESC    : constant Character := esc;
18     FS     : constant Character := fs;    GS     : constant Character := gs;
19     RS     : constant Character := rs;    US     : constant Character := us;
20     DEL    : constant Character := del;
21
22     -- Other characters:
23     Exclam  : constant Character:= '!';  Quotation : constant Character:= '"';
24     Sharp   : constant Character:= '#';  Dollar    : constant Character:= '$';
25     Percent : constant Character:= '%';  Ampersand : constant Character:= '&';
26     Colon   : constant Character:= ':';  Semicolon : constant Character:= ';';
27     Query   : constant Character:= '?';  At_Sign   : constant Character:= '@';
28     L_Bracket: constant Character:= '[';  Back_Slash: constant Character:= '\';
29     R_Bracket: constant Character:= ']';  Circumflex: constant Character:= '^';
30     Underline: constant Character:= '_';  Grave     : constant Character:= '`';
31     L_Brace  : constant Character:= '{';  Bar       : constant Character:= '|';
32     R_Brace  : constant Character:= '}';  Tilde     : constant Character:= '~';
33
34     -- Lower case letters:
35     LC_A: constant Character:= 'a';
36     ...
37     LC_Z: constant Character:= 'z';
38
39 end ASCII;
```

J.6 Numeric_Error

Static Semantics

The following declaration exists in the declaration of package Standard: 1

```
Numeric_Error : exception renames Constraint_Error;
```

 2

Discussion: This is true even though it is not shown in A.1. 2.a

Reason: In Ada 83, it was unclear which situations should raise `Numeric_Error`, and which should raise `Constraint_Error`. The permissions of RM83-11.6 could often be used to allow the implementation to raise `Constraint_Error` in a situation where one would normally expect `Numeric_Error`. To avoid this confusion, all situations that raise `Numeric_Error` in Ada 83 are changed to raise `Constraint_Error` in Ada 95. `Numeric_Error` is changed to be a renaming of `Constraint_Error` to avoid most of the upward compatibilities associated with this change. 2.b

In new code, `Constraint_Error` should be used instead of `Numeric_Error`. 2.c

J.7 At Clauses

Syntax

```
at_clause ::= for direct_name use at expression;
```

 1

Static Semantics

An `at_clause` of the form “for *x* use at *y*;” is equivalent to an `attribute_definition_clause` of the form “for *x*'Address use *y*;”. 2

Reason: The preferred syntax for specifying the address of an entity is an `attribute_definition_clause` specifying the `Address` attribute. Therefore, the special-purpose `at_clause` syntax is now obsolete. 2.a

The above equivalence implies, for example, that only one `at_clause` is allowed for a given entity. Similarly, it is illegal to give both an `at_clause` and an `attribute_definition_clause` specifying the `Address` attribute. 2.b

Extensions to Ada 83

We now allow to define the address of an entity using an `attribute_definition_clause`. This is because Ada 83's `at_clause` is so hard to remember: programmers often tend to write “for *X*'Address use...;”. 2.c

Wording Changes from Ada 83

Ada 83's `address_clause` is now called an `at_clause` to avoid confusion with the new term “Address clause” (that is, an `attribute_definition_clause` for the `Address` attribute). 2.d

J.7.1 Interrupt Entries

[Implementations are permitted to allow the attachment of task entries to interrupts via the address clause. Such an entry is referred to as an *interrupt entry*. 1

The address of the task entry corresponds to a hardware interrupt in an implementation-defined manner. (See `Ada.Interrupts.Reference` in C.3.2.)] 2

Static Semantics

The following attribute is defined: 3

For any task entry *X*: 4

X'Address For a task entry whose address is specified (an *interrupt entry*), the value refers to the corresponding hardware interrupt. For such an entry, as for any other task entry, the meaning of this value is implementation defined. The value of this attribute is of the type of the subtype `System.Address`. 5

6 Address may be specified for single entries via an `attribute_definition_clause`.

6.a **Reason:** Because of the equivalence of `at_clauses` and `attribute_definition_clauses`, an interrupt entry may be specified via either notation.

Dynamic Semantics

7 As part of the initialization of a task object, the address clause for an interrupt entry is elaborated[, which evaluates the `expression` of the address clause]. A check is made that the address specified is associated with some interrupt to which a task entry may be attached. If this check fails, `Program_Error` is raised. Otherwise, the interrupt entry is attached to the interrupt associated with the specified address.

8 Upon finalization of the task object, the interrupt entry, if any, is detached from the corresponding interrupt and the default treatment is restored.

9 While an interrupt entry is attached to an interrupt, the interrupt is reserved (see C.3).

10 An interrupt delivered to a task entry acts as a call to the entry issued by a hardware task whose priority is in the `System.Interrupt_Priority` range. It is implementation defined whether the call is performed as an ordinary entry call, a timed entry call, or a conditional entry call; which kind of call is performed can depend on the specific interrupt.

Bounded (Run-Time) Errors

11 It is a bounded error to evaluate `E'Caller` (see C.7.1) in an `accept_statement` for an interrupt entry. The possible effects are the same as for calling `Current_Task` from an entry body.

Documentation Requirements

12 The implementation shall document to which interrupts a task entry may be attached.

12.a/2 **Documentation Requirement:** The interrupts to which a task entry may be attached.

13 The implementation shall document whether the invocation of an interrupt entry has the effect of an ordinary entry call, conditional call, or a timed call, and whether the effect varies in the presence of pending interrupts.

13.a/2 **Documentation Requirement:** The type of entry call invoked for an interrupt entry.

Implementation Permissions

14 The support for this subclause is optional.

15 Interrupts to which the implementation allows a task entry to be attached may be designated as reserved for the entire duration of program execution[; that is, not just when they have an interrupt entry attached to them].

16/1 `{8652/0077}` `{AI95-00111-01}` Interrupt entry calls may be implemented by having the hardware execute directly the appropriate `accept_statement`. Alternatively, the implementation is allowed to provide an internal interrupt handler to simulate the effect of a normal task calling the entry.

17 The implementation is allowed to impose restrictions on the specifications and bodies of tasks that have interrupt entries.

18 It is implementation defined whether direct calls (from the program) to interrupt entries are allowed.

19 If a `select_statement` contains both a `terminate_alternative` and an `accept_alternative` for an interrupt entry, then an implementation is allowed to impose further requirements for the selection of the `terminate_alternative` in addition to those given in 9.3.

NOTES

- 1 {8652/0077} {AI95-00111-01} Queued interrupts correspond to ordinary entry calls. Interrupts that are lost if not immediately processed correspond to conditional entry calls. It is a consequence of the priority rules that an `accept_statement` executed in response to an interrupt can be executed with the active priority at which the hardware generates the interrupt, taking precedence over lower priority tasks, without a scheduling action. 20/1
- 2 Control information that is supplied upon an interrupt can be passed to an associated interrupt entry as one or more parameters of mode `in`. 21

*Examples**Example of an interrupt entry:*

```
task Interrupt_Handler is
  entry Done;
  for Done'Address use Ada.Interrupts.Reference(Ada.Interrupts.Names.Device_Done);
end Interrupt_Handler;
```

Wording Changes from Ada 83

{AI95-00114-01} RM83-13.5.1 did not adequately address the problems associated with interrupts. This feature is now obsolescent and is replaced by the Ada 95 interrupt model as specified in the Systems Programming Annex. 23.a/2

Wording Changes from Ada 95

{8652/0077} {AI95-00111-01} **Corrigendum:** The undefined term *accept body* was replaced by `accept_statement`. 23.b/2

J.8 Mod Clauses

Syntax

`mod_clause ::= at mod static_expression;` 1

Static Semantics

A `record_representation_clause` of the form: 2

```
{AI05-0092-1} for r use
  record at mod a;
  ...
end record;
```

is equivalent to: 4

```
for r'Alignment use a;
for r use
  record
  ...
end record;
```

Reason: The preferred syntax for specifying the alignment of an entity is an `attribute_definition_clause` specifying the Alignment attribute. Therefore, the special-purpose `mod_clause` syntax is now obsolete. 5.a

The above equivalence implies, for example, that it is illegal to give both a `mod_clause` and an `attribute_definition_clause` specifying the Alignment attribute for the same type. 5.b

Wording Changes from Ada 83

Ada 83's `alignment_clause` is now called a `mod_clause` to avoid confusion with the new term “Alignment clause” (that is, an `attribute_definition_clause` for the Alignment attribute). 5.c

J.9 The Storage_Size Attribute

Static Semantics

For any task subtype T, the following attribute is defined: 1

2 T'Storage_Size
Denotes an implementation-defined value of type *universal_integer* representing the number of storage elements reserved for a task of the subtype T.

2.a/3 **To be honest:** {AI05-0229-1} T'Storage_Size cannot be particularly meaningful in the presence of the specification of the aspect Storage_Size, especially when the expression is dynamic, or depends on a discriminant of the task, because the Storage_Size will be different for different objects of the type. Even without such a specification, the Storage_Size can be different for different objects of the type, and in any case, the value is implementation defined. Hence, it is always implementation defined.

3/3 {AI95-00345-01} {AI05-0229-1} Storage_Size may be specified for a task first subtype that is not an interface via an **attribute_definition_clause**. When the attribute is specified, the Storage_Size aspect is specified to be the value of the given expression.

3.a/3 **Ramification:** {AI05-0229-1} When this attribute is specified with an **attribute_definition_clause**, the associated aspect is set to the *value* of the expression given in the **attribute_definition_clause**, rather than the expression itself. This value is therefore the same for all objects of the type; in particular, it is not re-evaluated when objects are created. This is different than when the aspect is specified with an **aspect_specification** (see 13.3).

Wording Changes from Ada 95

3.b/2 {AI95-00345-01} We don't allow specifying Storage_Size on task interfaces. We don't need to mention class-wide task types, because these cannot be a first subtype.

J.10 Specific Suppression of Checks

1/2 {AI95-00224-01} Pragma Suppress can be used to suppress checks on specific entities.

Syntax

2/2 {AI95-00224-01} The form of a specific Suppress pragma is as follows:

3/2 **pragma Suppress**(identifier, [On =>] name);

Legality Rules

4/2 {AI95-00224-01} The identifier shall be the name of a check (see 11.5). The name shall statically denote some entity.

5/2 {AI95-00224-01} For a specific Suppress pragma that is immediately within a **package_specification**, the name shall denote an entity (or several overloaded subprograms) declared immediately within the **package_specification**.

Static Semantics

6/2 {AI95-00224-01} A specific Suppress pragma applies to the named check from the place of the pragma to the end of the innermost enclosing declarative region, or, if the pragma is given in a **package_specification**, to the end of the scope of the named entity. The pragma applies only to the named entity, or, for a subtype, on objects and values of its type. A specific Suppress pragma suppresses the named check for any entities to which it applies (see 11.5). Which checks are associated with a specific entity is not defined by this International Standard.

6.a/2 **Discussion:** The language doesn't specify exactly which entities control whether a check is performed. For example, in

6.b

```
pragma Suppress (Range_Check, On => A);
A := B;
```

6.c whether or not the range check is performed is not specified. The compiler may require that checks are suppressed on B or on the type of A in order to omit the range check.

Implementation Permissions

7/2 {AI95-00224-01} An implementation is allowed to place restrictions on specific Suppress pragmas.

NOTES

3 {AI95-00224-01} An implementation may support a similar On parameter on pragma Unsuppress (see 11.5). 8/2

Wording Changes from Ada 95

{AI95-00224-01} {AI05-0299-1} This subclause is new. This feature was moved here because it is important for pragma Unsuppress that there be an unambiguous meaning for each checking pragma. For instance, in the example 8.a/3

```
pragma Suppress (Range_Check);
pragma Unsuppress (Range_Check, On => A);
A := B;
```

8.b

the user needs to be able to depend on the range check being made on the assignment. But a compiler survey showed that the interpretation of this feature varied widely; trying to define this carefully was likely to cause a lot of user and implementer pain. Thus the feature was moved here, to emphasize that its use is not portable. 8.c

J.11 The Class Attribute of Untagged Incomplete Types

Static Semantics

{AI95-00326-01} For the first subtype S of a type T declared by an incomplete_type_declaration that is not tagged, the following attribute is defined: 1/2

{AI95-00326-01} S'Class 2/2

Denotes the first subtype of the incomplete class-wide type rooted at T. The completion of T shall declare a tagged type. Such an attribute reference shall occur in the same library unit as the incomplete_type_declaration.

Reason: {AI95-00326-01} This must occur in the same unit to prevent children from imposing requirements on their ancestor library units for deferred incomplete types. 2.a/2

Wording Changes from Ada 95

{AI95-00326-01} {AI05-0299-1} This subclause is new. This feature was moved here because the tagged incomplete type provides a better way to provide this capability (it doesn't put requirements on the completion based on uses that could be anywhere). Pity we didn't think of it in 1994. 2.b/3

J.12 Pragma Interface

Syntax

{AI95-00284-02} In addition to an identifier, the reserved word **interface** is allowed as a pragma name, to provide compatibility with a prior edition of this International Standard. 1/2

Implementation Note: {AI95-00284-02} All implementations need to at least recognize and ignore this pragma. A syntax error is not an acceptable implementation of this pragma. 1.a/2

Wording Changes from Ada 95

{AI95-00326-01} {AI05-0299-1} This subclause is new. This is necessary as **interface** is now a reserved word, which would prevent pragma Interface from being an implementation-defined pragma. We don't define any semantics for this pragma, as we expect that implementations will continue to use whatever they currently implement - requiring any changes would be counter-productive. 1.b/3

J.13 Dependence Restriction Identifiers

{AI95-00394-01} The following restrictions involve dependence on specific language-defined units. The more general restriction No_Dependence (see 13.12.1) should be used for this purpose. 1/2

Static Semantics

{AI95-00394-01} The following *restriction_identifiers* exist: 2/2

- 3/2 {AI95-00394-01} No_Aynchronous_Control
Semantic dependence on the predefined package Asynchronous_Task_Control is not allowed.
- 4/2 {AI95-00394-01} No_Unchecked_Conversion
Semantic dependence on the predefined generic function Unchecked_Conversion is not allowed.
- 5/2 {AI95-00394-01} No_Unchecked_Deallocation
Semantic dependence on the predefined generic procedure Unchecked_Deallocation is not allowed.

Wording Changes from Ada 95

- 5.a/3 {AI95-00394-01} {AI05-0299-1} This subclause is new. These restrictions are replaced by the more general No_Dependence (see 13.12.1).

J.14 Character and Wide_Character Conversion Functions*Static Semantics*

- 1/2 {AI95-00395-01} The following declarations exist in the declaration of package Ada.Characters.Handling:
- 2/2 **function** Is_Character (Item : **in** Wide_Character) **return** Boolean
 renames Conversions.Is_Character;
 function Is_String (Item : **in** Wide_String) **return** Boolean
 renames Conversions.Is_String;
- 3/2 **function** To_Character (Item : **in** Wide_Character;
 Substitute : **in** Character := ' ')
 return Character
 renames Conversions.To_Character;
- 4/2 **function** To_String (Item : **in** Wide_String;
 Substitute : **in** Character := ' ')
 return String
 renames Conversions.To_String;
- 5/2 **function** To_Wide_Character (Item : **in** Character) **return** Wide_Character
 renames Conversions.To_Wide_Character;
- 6/2 **function** To_Wide_String (Item : **in** String) **return** Wide_String
 renames Conversions.To_Wide_String;

Wording Changes from Ada 95

- 6.a/3 {AI95-00394-01} {AI05-0299-1} This subclause is new. These subprograms were moved to Characters.Conversions (see A.3.4).

J.15 Aspect-related Pragmas

- 1/3 {AI05-0229-1} Pragmas can be used as an alternative to aspect_specifications to specify certain aspects.

Wording Changes from Ada 2005

- 1.a/3 {AI05-0229-1} {AI05-0299-1} This subclause is new. Many existing pragmas have been converted into aspects; the pragmas have moved here.

J.15.1 Pragma Inline*Syntax*

- 1/3 {AI05-0229-1} The form of a pragma Inline, which is a program unit pragma (see 10.1.5), is as follows:

pragma Inline (name {, name}); 2/3

Legality Rules

{AI05-0229-1} The pragma shall apply to one or more callable entities or generic subprograms. 3/3

Static Semantics

{AI05-0229-1} Pragma Inline specifies that the Inline aspect (see 6.3.2) for each entity denoted by each name given in the pragma has the value True. 4/3

Ramification: Note that inline expansion is desired no matter what name is used in the call. This allows one to request inlining for only one of several overloaded subprograms as follows: 4.a/3

```

package IO is
  procedure Put(X : in Integer);
  procedure Put(X : in String);
  procedure Put(X : in Character);
private
  procedure Character_Put(X : in Character) renames Put;
  pragma Inline(Character_Put);
end IO;

with IO; use IO;
procedure Main is
  I : Integer;
  C : Character;
begin
  ...
  Put(C); -- Inline expansion is desired.
  Put(I); -- Inline expansion is NOT desired.
end Main;

```

4.b/3

4.c/3

Implementation Permissions

{AI05-0229-1} An implementation may allow a pragma Inline that has an argument which is a direct_name denoting a subprogram_body of the same declarative_part. 5/3

Reason: This is allowed for Ada 83 compatibility. This is only a permission as this usage was considered obsolescent even for Ada 95. 5.a/3

Discussion: We only need to allow this in declarative_parts, because a body is only allowed in another body, and these all have declarative_parts. 5.b/3

NOTES

4 {AI05-0229-1} The name in a pragma Inline may denote more than one entity in the case of overloading. Such a pragma applies to all of the denoted entities. 6/3

Incompatibilities With Ada 83

{AI95-00309-01} {AI05-0229-1} A pragma Inline cannot refer to a subprogram_body outside of that body. The pragma can be given inside of the subprogram body. Ada 2005 adds an Implementation Permission to allow this usage for compatibility (and Ada 95 implementations also can use this permission), but implementations do not have to allow such pragmas. 6.a/3

Extensions to Ada 83

{AI05-0229-1} A pragma Inline is allowed inside a subprogram_body if there is no corresponding subprogram_declaration. This is for uniformity with other program unit pragmas. 6.b/3

Extensions to Ada 95

{AI95-00309-01} {AI05-0229-1} **Amendment Correction:** Implementations are allowed to let Pragma Inline apply to a subprogram_body. 6.c/3

Wording Changes from Ada 2005

{AI05-0229-1} {AI05-0299-1} This subclause is new. Pragma Inline was moved here from 6.3.2; aspect Inline lives there now. 6.d/3

J.15.2 Pragma No_Return

Syntax

1/3 {AI05-0229-1} The form of a pragma No_Return, which is a representation pragma (see 13.1), is as follows:

2/3 **pragma** No_Return (*procedure_local_name*{, *procedure_local_name*});

Legality Rules

3/3 {AI05-0229-1} Each *procedure_local_name* shall denote one or more procedures or generic procedures. [The *procedure_local_name* shall not denote a null procedure nor an instance of a generic unit.]

Static Semantics

4/3 {AI05-0229-1} Pragma No_Return specifies that the No_Return aspect (see 6.5.1) for each procedure denoted by each *local_name* given in the pragma has the value True.

Wording Changes from Ada 2005

4.a/3 {AI05-0229-1} {AI05-0299-1} This subclause is new. Pragma No_Return was moved here from 6.5.1; aspect No_Return lives there now.

J.15.3 Pragma Pack

Syntax

1/3 {AI05-0229-1} The form of a pragma Pack, which is a representation pragma (see 13.1), is as follows:

2/3 **pragma** Pack (*first_subtype_local_name*);

Legality Rules

3/3 {AI05-0229-1} The *first_subtype_local_name* of a pragma Pack shall denote a composite subtype.

Static Semantics

4/3 {AI05-0229-1} Pragma Pack specifies that the Pack aspect (see 13.2) for the type denoted by *first_subtype_local_name* has the value True.

Wording Changes from Ada 2005

4.a/3 {AI05-0229-1} {AI05-0299-1} This subclause is new. Pragma Pack was moved here from 13.2; aspect Pack lives there now.

J.15.4 Pragma Storage_Size

Syntax

1/3 {AI05-0229-1} The form of a pragma Storage_Size is as follows:

2/3 **pragma** Storage_Size (*expression*);

3/3 {AI05-0229-1} A pragma Storage_Size is allowed only immediately within a *task_definition*.

Name Resolution Rules

4/3 {AI05-0229-1} The *expression* of a pragma Storage_Size is expected to be of any integer type.

Static Semantics

{AI05-0229-1} The pragma `Storage_Size` sets the `Storage_Size` aspect (see 13.3) of the type defined by the immediately enclosing `task_definition` to the value of the expression of the pragma. 5/3

Wording Changes from Ada 2005

{AI05-0229-1} {AI05-0299-1} This subclause is new. Pragma `Storage_Size` was moved here from 13.3; aspect `Storage_Size` lives there now. 5.a/3

J.15.5 Interfacing Pragmas*Syntax*

{AI05-0229-1} An *interfacing pragma* is a representation pragma that is one of the pragmas `Import`, `Export`, or `Convention`. Their forms are as follows: 1/3

```
pragma Import(
  [Convention =>] convention_identifier, [Entity =>] local_name
  [, [External_Name =>] external_name_string_expression]
  [, [Link_Name =>] link_name_string_expression]);
```

 2/3

```
pragma Export(
  [Convention =>] convention_identifier, [Entity =>] local_name
  [, [External_Name =>] external_name_string_expression]
  [, [Link_Name =>] link_name_string_expression]);
```

 3/3

```
pragma Convention([Convention =>] convention_identifier, [Entity =>] local_name);
```

 4/3

{AI05-0229-1} For pragmas `Import` and `Export`, the argument for `Link_Name` shall not be given without the *pragma_argument_identifier* unless the argument for `External_Name` is given. 5/3

Name Resolution Rules

{AI05-0229-1} The expected type for an *external_name_string_expression* and a *link_name_string_expression* in an interfacing pragma is `String`. 6/3

Legality Rules

{AI05-0229-1} The *convention_identifier* of an interfacing pragma shall be the name of a convention (see B.1). 7/3

{AI05-0229-1} A pragma `Import` shall be the completion of a declaration. Notwithstanding any rule to the contrary, a pragma `Import` may serve as the completion of any kind of (explicit) declaration if supported by an implementation for that kind of declaration. If a completion is a pragma `Import`, then it shall appear in the same `declarative_part`, `package_specification`, `task_definition`, or `protected_definition` as the declaration. For a library unit, it shall appear in the same compilation, before any subsequent compilation_units other than pragmas. If the *local_name* denotes more than one entity, then the pragma `Import` is the completion of all of them. 8/3

{AI05-0229-1} The *external_name_string_expression* and *link_name_string_expression* of a pragma `Import` or `Export` shall be static. 9/3

{AI05-0229-1} The *local_name* of each of these pragmas shall denote a declaration that may have the similarly named aspect specified. 10/3

Static Semantics

{AI05-0229-1} An interfacing pragma specifies various aspects of the entity denoted by the *local_name* as follows: 11/3

- 12/3 • The Convention aspect (see B.1) is *convention_identifier*.
- 13/3 • A pragma Import specifies that the Import aspect (see B.1) is True.
- 14/3 • A pragma Export specifies that the Export aspect (see B.1) is True.
- 15/3 • For both pragma Import and Export, if an external name is given in the pragma, the External_Name aspect (see B.1) is specified to be *external_name_string_expression*. If a link name is given in the pragma, the Link_Name aspect (see B.1) is specified to be the *link_name_string_expression*.

Wording Changes from Ada 2005

- 15.a/3 {AI05-0229-1} {AI05-0299-1} This subclause is new. Pragmas Import, Export, and Convention were moved here from B.1; aspects Import, Export, Convention, Link_Name, and External_Name live there now.

J.15.6 Pragma Unchecked_Union

Syntax

- 1/3 {AI05-0229-1} The form of a pragma Unchecked_Union, which is a representation pragma (see 13.1), is as follows:

2/3 **pragma** Unchecked_Union (*first_subtype_local_name*);

Legality Rules

- 3/3 {AI05-0229-1} The *first_subtype_local_name* of a pragma Unchecked_Union shall denote an unconstrained discriminated record subtype having a *variant_part*.

Static Semantics

- 4/3 {AI05-0229-1} A pragma Unchecked_Union specifies that the Unchecked_Union aspect (see B.3.3) for the type denoted by *first_subtype_local_name* has the value True.

Wording Changes from Ada 2005

- 4.a/3 {AI05-0229-1} {AI05-0299-1} This subclause is new. Pragma Unchecked_Union was moved here from B.3.3; aspect Unchecked_Union lives there now.

J.15.7 Pragmas Interrupt_Handler and Attach_Handler

Syntax

- 1/3 {AI05-0229-1} The form of a pragma Interrupt_Handler is as follows:

2/3 **pragma** Interrupt_Handler (*handler_name*);

- 3/3 {AI05-0229-1} The form of a pragma Attach_Handler is as follows:

4/3 **pragma** Attach_Handler (*handler_name*, *expression*);

Name Resolution Rules

- 5/3 {AI05-0229-1} For the Interrupt_Handler and Attach_Handler pragmas, the *handler_name* shall resolve to denote a protected procedure with a parameterless profile.

- 6/3 {AI05-0229-1} For the Attach_Handler pragma, the expected type for the expression is Interrupts.Interrupt_Id (see C.3.2).

Legality Rules

{AI05-0033-1} {AI05-0229-1} The `Attach_Handler` and `Interrupt_Handler` pragmas are only allowed immediately within the `protected_definition` where the corresponding subprogram is declared. The corresponding `protected_type_declaration` or `single_protected_declaration` shall be a library-level declaration, and shall not be declared within a generic body. In addition to the places where Legality Rules normally apply (see 12.3), these rules also apply in the private part of an instance of a generic unit. 7/3

Discussion: In the case of a `protected_type_declaration`, an `object_declaration` of an object of that type need not be at library level. 7.a/3

{AI05-0033-1} We cannot allow these pragmas in a generic body, because legality rules are not checked for instance bodies, and these should not be allowed if the instance is not at the library level. The protected types can be declared in the private part if this is desired. Note that while the 'Access to use the handler would provide the check in the case of `Interrupt_Handler`, there is no other check for `Attach_Handler`. Since these pragmas are so similar, we want the rules to be the same. 7.b/3

Static Semantics

{AI05-0229-1} For an implementation that supports Annex C, a pragma `Interrupt_Handler` specifies the `Interrupt_Handler` aspect (see C.3.1) for the protected procedure `handler_name` to have the value `True`. For an implementation that supports Annex C, a pragma `Attach_Handler` specifies the `Attach_Handler` aspect (see C.3.1) for the protected procedure `handler_name` to have the value of the given `expression`[as evaluated at object creation time]. 8/3

Incompatibilities With Ada 2005

{AI05-0033-1} **Correction:** Added missing generic contract wording for the pragma `Attach_Handler` and `Interrupt_Handler`. This means that nested instances with these pragmas in the private part are now illegal. This is not likely to occur in practice. 8.a/3

Wording Changes from Ada 2005

{AI05-0229-1} {AI05-0299-1} This subclause is new. Pragmas `Interrupt_Handler` and `Attach_Handler` were moved here from C.3.1; aspects `Interrupt_Handler` and `Attach_Handler` live there now. 8.b/3

J.15.8 Shared Variable Pragmas

Syntax

{AI05-0229-1} The form for pragmas `Atomic`, `Volatile`, `Independent`, `Atomic_Components`, and `Volatile_Components`, and `Independent_Components` is as follows: 1/3

pragma `Atomic` (`local_name`); 2/3

pragma `Volatile` (`local_name`); 3/3

{AI05-0009-1} **pragma** `Independent` (`component_local_name`); 4/3

pragma `Atomic_Components` (`array_local_name`); 5/3

pragma `Volatile_Components` (`array_local_name`); 6/3

{AI05-0009-1} **pragma** `Independent_Components` (`local_name`); 7/3

Discussion: {AI05-0009-1} {AI05-0229-1} Pragmas `Independent` and `Independent_Components` are born obsolescent; they are defined to provide consistency with the existing shared variable pragmas. As with all obsolescent features, these pragmas are not optional; all Ada implementations need to implement them. Also note that these pragmas were defined as a **Correction**; as such, they are expected to be implemented as part of Ada 2005 implementations (and they would not be obsolescent there). 7.a/3

Name Resolution Rules

{AI05-0009-1} {AI05-0229-1} The `local_name` in an `Atomic` or `Volatile` pragma shall resolve to denote either an `object_declaration`, a noninherited `component_declaration`, or a `full_type_declaration`. The 8/3

component_local_name in an Independent pragma shall resolve to denote a noninherited *component_declaration*. The *array_local_name* in an Atomic_Components or Volatile_Components pragma shall resolve to denote the declaration of an array type or an array object of an anonymous type. The *local_name* in an Independent_Components pragma shall resolve to denote the declaration of an array or record type or an array object of an anonymous type.

Static Semantics

- 9/3 {AI05-0229-1} These pragmas are representation pragmas (see 13.1). Each of these pragmas specifies that the similarly named aspect (see C.6) of the type, object, or component denoted by its argument is True.

Legality Rules

- 10/3 {AI05-0229-1} The *local_name* of each of these pragmas shall denote a declaration that may have the similarly named aspect specified.

Wording Changes from Ada 2005

- 10.a/3 {AI05-0229-1} {AI05-0299-1} This subclause is new. These pragmas were moved here from C.6; various aspects live there now.

J.15.9 Pragma CPU

- 0.a/3 **Discussion:** {AI05-0229-1} This pragma is born obsolescent; it is defined to provide consistency with existing real-time pragmas. As with all obsolescent features, this pragma is not optional; all Ada implementations need to implement it.

Syntax

- 1/3 {AI05-0229-1} The form of a pragma CPU is as follows:
2/3 **pragma CPU (expression);**

Name Resolution Rules

- 3/3 {AI05-0229-1} The expected type for the expression of a pragma CPU is System.Multiprocessors.CPU_Range.

Legality Rules

- 4/3 {AI05-0229-1} A CPU pragma is allowed only immediately within a *task_definition*, or the *declarative_part* of a *subprogram_body*.
5/3 {AI05-0229-1} For a CPU pragma that appears in the *declarative_part* of a *subprogram_body*, the expression shall be static.

Static Semantics

- 6/3 {AI05-0229-1} For an implementation that supports Annex D, a pragma CPU specifies the value of the CPU aspect (see D.16). If the pragma appears in a *task_definition*, the expression is associated with the aspect for the task type or *single_task_declaration* that contains the pragma; otherwise, the expression is associated with the aspect for the subprogram that contains the pragma.

Extensions to Ada 2005

- 6.a/3 {AI05-0009-1} Pragma CPU is new.

J.15.10 Pragma Dispatching_Domain

Discussion: *{AI05-0167-1}* This pragma is born obsolescent; it is defined to provide consistency with existing real-time pragmas. As with all obsolescent features, this pragma is not optional; all Ada implementations need to implement it. 0.a/3

Syntax

{AI05-0167-1} The form of a pragma Dispatching_Domain is as follows: 1/3

pragma Dispatching_Domain (expression); 2/3

Name Resolution Rules

{AI05-0167-1} The expected type for the expression is System.Multiprocessors.Dispatching_Domains.Dispatching_Domain. 3/3

Legality Rules

{AI05-0167-1} A Dispatching_Domain pragma is allowed only immediately within a task_definition. 4/3

Static Semantics

{AI05-0167-1} For an implementation that supports Annex D, a pragma Dispatching_Domain specifies the value of the Dispatching_Domain aspect (see D.16.1). The expression is associated with the aspect for the task type or single_task_declaration that contains the pragma. 5/3

Extensions to Ada 2005

{AI05-0009-1} Pragma Dispatching_Domain is new. 5.a/3

J.15.11 Pragmas Priority and Interrupt_Priority

Syntax

{AI05-0229-1} The form of a pragma Priority is as follows: 1/3

pragma Priority (expression); 2/3

{AI05-0229-1} The form of a pragma Interrupt_Priority is as follows: 3/3

pragma Interrupt_Priority [(expression);] 4/3

Name Resolution Rules

{AI05-0229-1} The expected type for the expression in a Priority or Interrupt_Priority pragma is Integer. 5/3

Legality Rules

{AI05-0229-1} A Priority pragma is allowed only immediately within a task_definition, a protected_definition, or the declarative_part of a subprogram_body. An Interrupt_Priority pragma is allowed only immediately within a task_definition or a protected_definition. 6/3

{AI05-0229-1} For a Priority pragma that appears in the declarative_part of a subprogram_body, the expression shall be static, and its value shall be in the range of System.Priority. 7/3

Static Semantics

{AI05-0229-1} For an implementation that supports Annex D, a pragma Priority specifies the value of the Priority aspect (see D.1) and a pragma Interrupt_Priority specifies the value of the Interrupt_Priority aspect as follows: 8/3

- 9/3 • If the pragma appears in a `task_definition`, the expression is associated with the aspect for the task type or `single_task_declaration` that contains the pragma;
 - 10/3 • If the pragma appears in a `protected_definition`, the expression is associated with the aspect for the protected type or `single_protected_declaration` that contains the pragma;
 - 11/3 • If the pragma appears in the `declarative_part` of a `subprogram_body`, the expression is associated with the aspect for the subprogram that contains the pragma.
- 12/3 *{AI05-0229-1}* If there is no expression in an `Interrupt_Priority` pragma, the `Interrupt_Priority` aspect has the value `Interrupt_Priority'Last`.

Wording Changes from Ada 2005

- 12.a/3 *{AI05-0229-1}* *{AI05-0299-1}* This subclause is new. Pragas `Interrupt_Priority` and `Priority` were moved here from D.1; aspects `Interrupt_Priority` and `Priority` live there now.

J.15.12 Pragma `Relative_Deadline`

Syntax

- 1/3 *{AI05-0229-1}* The form of a pragma `Relative_Deadline` is as follows:
- 2/3 **pragma** `Relative_Deadline` (*relative_deadline_expression*);

Name Resolution Rules

- 3/3 *{AI05-0229-1}* The expected type for a *relative_deadline_expression* is `Real_Time.Time_Span`.

Legality Rules

- 4/3 *{AI05-0229-1}* A `Relative_Deadline` pragma is allowed only immediately within a `task_definition` or the `declarative_part` of a `subprogram_body`.

Static Semantics

- 5/3 *{AI05-0229-1}* For an implementation that supports Annex D, a pragma `Relative_Deadline` specifies the value of the `Relative_Deadline` aspect (see D.2.6). If the pragma appears in a `task_definition`, the expression is associated with the aspect for the task type or `single_task_declaration` that contains the pragma; otherwise, the expression is associated with the aspect for the subprogram that contains the pragma.

Wording Changes from Ada 2005

- 5.a/3 *{AI05-0229-1}* *{AI05-0299-1}* This subclause is new. Pragma `Relative_Deadline` was moved here from D.2.6; aspect `Relative_Deadline` lives there now.

J.15.13 Pragma `Asynchronous`

Syntax

- 1/3 *{AI05-0229-1}* The form of a pragma `Asynchronous`, which is a representation pragma (see 13.1), is as follows:
- 2/3 **pragma** `Asynchronous` (*local_name*);

Static Semantics

- 3/3 *{AI05-0229-1}* For an implementation that supports Annex E, a pragma `Asynchronous` specifies that the `Asynchronous` aspect (see E.4.1) for the procedure or type denoted by *local_name* has the value `True`.

Legality Rules

{AI05-0229-1} The `local_name` of a pragma `Asynchronous` shall denote a declaration that may have aspect `Asynchronous` specified. 4/3

Wording Changes from Ada 2005

{AI05-0229-1} {AI05-0299-1} This subclause is new. Pragma `Asynchronous` was moved here from E.4.1; aspect `Asynchronous` lives there now. 4.a/3

Annex K

(informative)

Language-Defined Aspects and Attributes

{AI05-0229-1} This annex summarizes the definitions given elsewhere of the language-defined aspects and attributes. Some aspects have corresponding attributes, as noted. 1/3

K.1 Language-Defined Aspects

{AI05-0229-1} *{AI05-0299-1}* This subclause summarizes the definitions given elsewhere of the language-defined aspects. Aspects are properties of entities that can be specified by the Ada program; unless otherwise specified below, aspects can be specified using an `aspect_specification`. 1/3

`Address` Machine address of an entity. See 13.3. 2/3

`Alignment (object)` Alignment of an object. See 13.3. 3/3

`Alignment (subtype)` Alignment of a subtype. See 13.3. 4/3

`All_Calls_Remote` All remote procedure calls should use the Partition Communication Subsystem, even if they are local. See E.2.3. 5/3

`Asynchronous` Remote procedure calls are asynchronous; the caller continues without waiting for the call to return. See E.4.1. 6/3

`Atomic` Declare that a type, object, or component is atomic. See C.6. 7/3

`Atomic_Components` Declare that the components of an array type or object are atomic. See C.6. 8/3

`Attach_Handler` Protected procedure is attached to an interrupt. See C.3.1. 9/3

`Bit_Order` Order of bit numbering in a `record_representation_clause`. See 13.5.3. 10/3

`Coding` Internal representation of enumeration literals. Specified by an `enumeration_representation_clause`, not by an `aspect_specification`. See 13.4. 11/3

`Component_Size` Size in bits of a component of an array type. See 13.3. 12/3

`Constant_Indexing` Defines function(s) to implement user-defined `indexed_components`. See 4.1.6. 13/3

`Convention` Calling convention or other convention used for interfacing to other languages. See B.1. 14/3

`CPU` Processor on which a given task should run. See D.16. 15/3

`Default_Component_Value` Default value for the components of an array-of-scalar subtype. See 3.6. 16/3

`Default_Iterator` Default iterator to be used in `for` loops. See 5.5.1. 17/3

`Default_Storage_Pool` Default storage pool for a generic instance. See 13.11.3. 18/3

- 19/3 **Default_Value**
 Default value for a scalar subtype. See 3.5.
- 20/3 **Dispatching_Domain**
 Domain (group of processors) on which a given task should run. See D.16.1.
- 21/3 **Dynamic_Predicate**
 Condition that must hold true for objects of a given subtype; the subtype is not static. See 3.2.4.
- 22/3 **Elaborate_Body**
 A given package must have a body, and that body is elaborated immediately after the declaration. See 10.2.1.
- 23/3 **Export** Entity is exported to another language. See B.1.
- 24/3 **External_Name**
 Name used to identify an imported or exported entity. See B.1.
- 25/3 **External_Tag**
 Unique identifier for a tagged type in streams. See 13.3.
- 26/3 **Implicit_Dereference**
 Mechanism for user-defined implicit **.all**. See 4.1.5.
- 27/3 **Import** Entity is imported from another language. See B.1.
- 28/3 **Independent** Declare that a type, object, or component is independently addressable. See C.6.
- 29/3 **Independent_Components**
 Declare that the components of an array or record type, or an array object, are independently addressable. See C.6.
- 30/3 **Inline** For efficiency, Inline calls are requested for a subprogram. See 6.3.2.
- 31/3 **Input** Function to read a value from a stream for a given type, including any bounds and discriminants. See 13.13.2.
- 32/3 **Interrupt_Handler**
 Protected procedure may be attached to interrupts. See C.3.1.
- 33/3 **Interrupt_Priority**
 Priority of a task object or type, or priority of a protected object or type; the priority is in the interrupt range. See D.1.
- 34/3 **Iterator_Element**
 Element type to be used for user-defined iterators. See 5.5.1.
- 35/3 **Layout (record)**
 Layout of record components. Specified by a `record_representation_clause`, not by an `aspect_specification`. See 13.5.1.
- 36/3 **Link_Name** Linker symbol used to identify an imported or exported entity. See B.1.
- 37/3 **Machine_Radix**
 Radix (2 or 10) that is used to represent a decimal fixed point type. See F.1.
- 38/3 **No_Return** A procedure will not return normally. See 6.5.1.
- 39/3 **Output** Procedure to write a value to a stream for a given type, including any bounds and discriminants. See 13.13.2.
- 40/3 **Pack** Minimize storage when laying out records and arrays. See 13.2.
- 41/3 **Post** Postcondition; a condition that must hold true after a call. See 6.1.1.

Post'Class	Postcondition inherited on type derivation. See 6.1.1.	42/3
Pre	Precondition; a condition that must hold true before a call. See 6.1.1.	43/3
Pre'Class	Precondition inherited on type derivation. See 6.1.1.	44/3
Preelaborate	Code execution during elaboration is avoided for a given package. See 10.2.1.	45/3
Priority	Priority of a task object or type, or priority of a protected object or type; the priority is not in the interrupt range. See D.1.	46/3
Pure	Side effects are avoided in the subprograms of a given package. See 10.2.1.	47/3
Read	Procedure to read a value from a stream for a given type. See 13.13.2.	48/3
Record layout	See Layout. See 13.5.1.	49/3
Relative_Deadline	Task parameter used in Earliest Deadline First Dispatching. See D.2.6.	50/3
Remote_Call_Interface	Subprograms in a given package may be used in remote procedure calls. See E.2.3.	51/3
Remote_Types	Types in a given package may be used in remote procedure calls. See E.2.2.	52/3
Shared_Passive	A given package is used to represent shared memory in a distributed system. See E.2.1.	53/3
Size (object)	Size in bits of an object. See 13.3.	54/3
Size (subtype)	Size in bits of a subtype. See 13.3.	55/3
Small	Scale factor for a fixed point type. See 3.5.10.	56/3
Static_Predicate	Condition that must hold true for objects of a given subtype; the subtype may be static. See 3.2.4.	57/3
Storage_Pool	Pool of memory from which new will allocate for a given access type. See 13.11.	58/3
Storage_Size (access)	Sets memory size for allocations for an access type. See 13.11.	59/3
Storage_Size (task)	Size in storage elements reserved for a task type or single task object. See 13.3.	60/3
Stream_Size	Size in bits used to represent elementary objects in a stream. See 13.13.2.	61/3
Synchronization	Defines whether a given primitive operation of a synchronized interface must be implemented by an entry or protected procedure. See 9.5.	62/3
Type_Invariant	A condition that must hold true for all objects of a type. See 7.3.2.	63/3
Type_Invariant'Class	A condition that must hold true for all objects in a class of types. See 7.3.2.	64/3

- 65/3 **Unchecked_Union**
Type is used to interface to a C union type. See B.3.3.
- 66/3 **Variable_Indexing**
Defines function(s) to implement user-defined `indexed_components`. See 4.1.6.
- 67/3 **Volatile** Declare that a type, object, or component is volatile. See C.6.
- 68/3 **Volatile_Components**
Declare that the components of an array type or object are volatile. See C.6.
- 69/3 **Write** Procedure to write a value to a stream for a given type. See 13.13.2.

K.2 Language-Defined Attributes

- 1/3 `{AI05-0229-1}` `{AI05-0299-1}` This subclause summarizes the definitions given elsewhere of the language-defined attributes. Attributes are properties of entities that can be queried by an Ada program.
- 2 **P'Access** For a prefix `P` that denotes a subprogram:
- 3 `P'Access` yields an access value that designates the subprogram denoted by `P`. The type of `P'Access` is an access-to-subprogram type (*S*), as determined by the expected type. See 3.10.2.
- 4 **X'Access** For a prefix `X` that denotes an aliased view of an object:
- 5 `X'Access` yields an access value that designates the object denoted by `X`. The type of `X'Access` is an access-to-object type, as determined by the expected type. The expected type shall be a general access type. See 3.10.2.
- 6/1 **X'Address** For a prefix `X` that denotes an object, program unit, or label:
- 7 Denotes the address of the first of the storage elements allocated to `X`. For a program unit or label, this value refers to the machine code associated with the corresponding body or statement. The value of this attribute is of type `System.Address`. See 13.3.
- 8 **S'Adjacent** For every subtype `S` of a floating point type `T`:
- 9 `S'Adjacent` denotes a function with the following specification:
- 10

```
function S'Adjacent (X, Towards : T)
return T
```
- 11 If `Towards = X`, the function yields `X`; otherwise, it yields the machine number of the type `T` adjacent to `X` in the direction of `Towards`, if that machine number exists. If the result would be outside the base range of `S`, `Constraint_Error` is raised. When `T'Signed_Zeros` is `True`, a zero result has the sign of `X`. When `Towards` is zero, its sign has no bearing on the result. See A.5.3.
- 12 **S'Aft** For every fixed point subtype `S`:
- 13 `S'Aft` yields the number of decimal digits needed after the decimal point to accommodate the *delta* of the subtype `S`, unless the *delta* of the subtype `S` is greater than 0.1, in which case the attribute yields the value one. (`S'Aft` is the smallest positive integer `N` for which $(10^{**N}) * S'Delta$ is greater than or equal to one.) The value of this attribute is of the type *universal_integer*. See 3.5.10.
- 13.1/2 **S'Alignment**
For every subtype `S`:
- 13.2/2 The value of this attribute is of type *universal_integer*, and nonnegative.
- 13.3/2 For an object `X` of subtype `S`, if `S'Alignment` is not zero, then `X'Alignment` is a nonzero integral multiple of `S'Alignment` unless specified otherwise by a representation item. See 13.3.

X'Alignment		14/1
	For a prefix <i>X</i> that denotes an object:	
	The value of this attribute is of type <i>universal_integer</i> , and nonnegative; zero means that the object is not necessarily aligned on a storage element boundary. If X'Alignment is not zero, then <i>X</i> is aligned on a storage unit boundary and X'Address is an integral multiple of X'Alignment (that is, the Address modulo the Alignment is zero).	15
	See 13.3.	16/2
S'Base	For every scalar subtype <i>S</i> :	17
	S'Base denotes an unconstrained subtype of the type of <i>S</i> . This unconstrained subtype is called the <i>base subtype</i> of the type. See 3.5.	18
S'Bit_Order	For every specific record subtype <i>S</i> :	19
	Denotes the bit ordering for the type of <i>S</i> . The value of this attribute is of type System.Bit_Order. See 13.5.3.	20
P'Body_Version	For a prefix <i>P</i> that statically denotes a program unit:	21/1
	Yields a value of the predefined type String that identifies the version of the compilation unit that contains the body (but not any subunits) of the program unit. See E.3.	22
T'Callable	For a prefix <i>T</i> that is of a task type (after any implicit dereference):	23
	Yields the value True when the task denoted by <i>T</i> is <i>callable</i> , and False otherwise; See 9.9.	24
E'Caller	For a prefix <i>E</i> that denotes an <i>entry_declaration</i> :	25
	Yields a value of the type Task_Id that identifies the task whose call is now being serviced. Use of this attribute is allowed only inside an <i>accept_statement</i> , or <i>entry_body</i> after the <i>entry_barrier</i> , corresponding to the <i>entry_declaration</i> denoted by <i>E</i> . See C.7.1.	26/3
S'Ceiling	For every subtype <i>S</i> of a floating point type <i>T</i> :	27
	S'Ceiling denotes a function with the following specification:	28
	<pre>function S'Ceiling (X : T) return T</pre>	29
	The function yields the value $\lceil X \rceil$, i.e., the smallest (most negative) integral value greater than or equal to <i>X</i> . When <i>X</i> is zero, the result has the sign of <i>X</i> ; a zero result otherwise has a negative sign when S'Signed_Zeros is True. See A.5.3.	30
S'Class	For every subtype <i>S</i> of a tagged type <i>T</i> (specific or class-wide):	31
	S'Class denotes a subtype of the class-wide type (called <i>TClass</i> in this International Standard) for the class rooted at <i>T</i> (or if <i>S</i> already denotes a class-wide subtype, then S'Class is the same as <i>S</i>).	32
	S'Class is unconstrained. However, if <i>S</i> is constrained, then the values of S'Class are only those that when converted to the type <i>T</i> belong to <i>S</i> . See 3.9.	33
S'Class	For every subtype <i>S</i> of an untagged private type whose full view is tagged:	34
	Denotes the class-wide subtype corresponding to the full view of <i>S</i> . This attribute is allowed only from the beginning of the private part in which the full view is declared, until the declaration of the full view. After the full view, the Class attribute of the full view can be used. See 7.3.1.	35
X'Component_Size	For a prefix <i>X</i> that denotes an array subtype or array object (after any implicit dereference):	36/1

- 37 Denotes the size in bits of components of the type of X. The value of this attribute is of type *universal_integer*. See 13.3.
- 38 S'Compose For every subtype S of a floating point type T:
- 39 S'Compose denotes a function with the following specification:
- 40

```
function S'Compose (Fraction : T;
                  Exponent : universal_integer)
return T
```
- 41 Let v be the value $Fraction \cdot TMachine_Radix^{Exponent-k}$, where k is the normalized exponent of *Fraction*. If v is a machine number of the type *T*, or if $|v| \geq TModel_Small$, the function yields v ; otherwise, it yields either one of the machine numbers of the type *T* adjacent to v . *Constraint_Error* is optionally raised if v is outside the base range of S. A zero result has the sign of *Fraction* when S'Signed_Zeros is True. See A.5.3.
- 42 A'Constrained For a prefix A that is of a discriminated type (after any implicit dereference):
- 43/3 Yields the value True if A denotes a constant, a value, a tagged object, or a constrained variable, and False otherwise. See 3.7.2.
- 44 S'Copy_Sign For every subtype S of a floating point type T:
- 45 S'Copy_Sign denotes a function with the following specification:
- 46

```
function S'Copy_Sign (Value, Sign : T)
return T
```
- 47 If the value of *Value* is nonzero, the function yields a result whose magnitude is that of *Value* and whose sign is that of *Sign*; otherwise, it yields the value zero. *Constraint_Error* is optionally raised if the result is outside the base range of S. A zero result has the sign of *Sign* when S'Signed_Zeros is True. See A.5.3.
- 48 E'Count For a prefix E that denotes an entry of a task or protected unit:
- 49 Yields the number of calls presently queued on the entry E of the current instance of the unit. The value of this attribute is of the type *universal_integer*. See 9.9.
- 50/1 S'Definite For a prefix S that denotes a formal indefinite subtype:
- 51/3 S'Definite yields True if the actual subtype corresponding to S is definite; otherwise, it yields False. The value of this attribute is of the predefined type Boolean. See 12.5.1.
- 52 S'Delta For every fixed point subtype S:
- 53 S'Delta denotes the *delta* of the fixed point subtype S. The value of this attribute is of the type *universal_real*. See 3.5.10.
- 54 S'Denorm For every subtype S of a floating point type T:
- 55 Yields the value True if every value expressible in the form
 $\pm mantissa \cdot TMachine_Radix^{TMachine_Emin}$
where *mantissa* is a nonzero *TMachine_Mantissa*-digit fraction in the number base *TMachine_Radix*, the first digit of which is zero, is a machine number (see 3.5.7) of the type *T*; yields the value False otherwise. The value of this attribute is of the predefined type Boolean. See A.5.3.
- 56 S'Digits For every floating point subtype S:
- 57 S'Digits denotes the requested decimal precision for the subtype S. The value of this attribute is of the type *universal_integer*. See 3.5.8.
- 58 S'Digits For every decimal fixed point subtype S:

	S'Digits denotes the <i>digits</i> of the decimal fixed point subtype S, which corresponds to the number of decimal digits that are representable in objects of the subtype. The value of this attribute is of the type <i>universal_integer</i> . See 3.5.10.	59
S'Exponent	For every subtype S of a floating point type T:	60
	S'Exponent denotes a function with the following specification:	61
	<pre>function S'Exponent (X : T) return universal_integer</pre>	62
	The function yields the normalized exponent of X. See A.5.3.	63
S'External_Tag		64
	For every subtype S of a tagged type T (specific or class-wide):	
	S'External_Tag denotes an external string representation for S'Tag; it is of the predefined type String. External_Tag may be specified for a specific tagged type via an <i>attribute_definition_clause</i> ; the expression of such a clause shall be static. The default external tag representation is implementation defined. See 13.13.2. See 13.3.	65
A'First	For a prefix A that is of an array type (after any implicit dereference), or denotes a constrained array subtype:	66/1
	A'First denotes the lower bound of the first index range; its type is the corresponding index type. See 3.6.2.	67
S'First	For every scalar subtype S:	68
	S'First denotes the lower bound of the range of S. The value of this attribute is of the type of S. See 3.5.	69
A'First(N)		70/1
	For a prefix A that is of an array type (after any implicit dereference), or denotes a constrained array subtype:	
	A'First(N) denotes the lower bound of the N-th index range; its type is the corresponding index type. See 3.6.2.	71
R.C'First_Bit		72
	For a component C of a composite, non-array object R:	
	If the nondefault bit ordering applies to the composite type, and if a <i>component_clause</i> specifies the placement of C, denotes the value given for the <i>first_bit</i> of the <i>component_clause</i> ; otherwise, denotes the offset, from the start of the first of the storage elements occupied by C, of the first bit occupied by C. This offset is measured in bits. The first bit of a storage element is numbered zero. The value of this attribute is of the type <i>universal_integer</i> . See 13.5.2.	73/2
S'First_Valid		73.1/3
	For every static discrete subtype S for which there exists at least one value belonging to S that satisfies any predicate of S:	
	S'First_Valid denotes the smallest value that belongs to S and satisfies the predicate of S. The value of this attribute is of the type of S. See 3.5.5.	73.2/3
S'Floor	For every subtype S of a floating point type T:	74
	S'Floor denotes a function with the following specification:	75
	<pre>function S'Floor (X : T) return T</pre>	76
	The function yields the value $\lfloor X \rfloor$, i.e., the largest (most positive) integral value less than or equal to X. When X is zero, the result has the sign of X; a zero result otherwise has a positive sign. See A.5.3.	77

- 78 S'Fore For every fixed point subtype S:
- 79 S'Fore yields the minimum number of characters needed before the decimal point for the decimal representation of any value of the subtype S, assuming that the representation does not include an exponent, but includes a one-character prefix that is either a minus sign or a space. (This minimum number does not include superfluous zeros or underlines, and is at least 2.) The value of this attribute is of the type *universal_integer*. See 3.5.10.
- 80 S'Fraction For every subtype S of a floating point type T:
- 81 S'Fraction denotes a function with the following specification:
- 82

```
function S'Fraction (X : T)
return T
```
- 83 The function yields the value $X \cdot TMachine_Radix^{-k}$, where k is the normalized exponent of X . A zero result, which can only occur when X is zero, has the sign of X . See A.5.3.
- 83.1/3 X'Has_Same_Storage For a prefix X that denotes an object:
- 83.2/3 X'Has_Same_Storage denotes a function with the following specification:
- 83.3/3

```
function X'Has_Same_Storage (Arg : any_type)
return Boolean
```
- 83.4/3 The actual parameter shall be a name that denotes an object. The object denoted by the actual parameter can be of any type. This function evaluates the names of the objects involved and returns True if the representation of the object denoted by the actual parameter occupies exactly the same bits as the representation of the object denoted by X; otherwise, it returns False. See 13.3.
- 84/1 E'Identity For a prefix E that denotes an exception:
- 85 E'Identity returns the unique identity of the exception. The type of this attribute is *Exception_Id*. See 11.4.1.
- 86 T'Identity For a prefix T that is of a task type (after any implicit dereference):
- 87 Yields a value of the type *Task_Id* that identifies the task denoted by T. See C.7.1.
- 88 S'Image For every scalar subtype S:
- 89 S'Image denotes a function with the following specification:
- 90

```
function S'Image (Arg : S'Base)
return String
```
- 91/3 The function returns an image of the value of *Arg* as a *String*. See 3.5.
- 92 S'Class'Input For every subtype S'Class of a class-wide type T'Class:
- 93 S'Class'Input denotes a function with the following specification:
- 94/2

```
function S'Class'Input (
Stream : not null access Ada.Streams.Root_Stream_Type'Class)
return T'Class
```
- 95/3 First reads the external tag from *Stream* and determines the corresponding internal tag (by calling *Tags.Descendant_Tag(String'Input(Stream), S'Tag)* which might raise *Tag_Error* — see 3.9) and then dispatches to the subprogram denoted by the *Input* attribute of the specific type identified by the internal tag; returns that result. If the specific type identified by the internal tag is abstract, *Constraint_Error* is raised. See 13.13.2.
- 96 S'Input For every subtype S of a specific type T:
- 97 S'Input denotes a function with the following specification:

	<pre> function S'Input (<i>Stream</i> : not null access Ada.Streams.Root_Stream_Type'Class) return T </pre>	98/2
	S'Input reads and returns one value from <i>Stream</i> , using any bounds or discriminants written by a corresponding S'Output to determine how much to read. See 13.13.2.	99
A'Last	For a prefix <i>A</i> that is of an array type (after any implicit dereference), or denotes a constrained array subtype:	100/1
	A'Last denotes the upper bound of the first index range; its type is the corresponding index type. See 3.6.2.	101
S'Last	For every scalar subtype <i>S</i> :	102
	S'Last denotes the upper bound of the range of <i>S</i> . The value of this attribute is of the type of <i>S</i> . See 3.5.	103
A'Last(N)	For a prefix <i>A</i> that is of an array type (after any implicit dereference), or denotes a constrained array subtype:	104/1
	A'Last(N) denotes the upper bound of the <i>N</i> -th index range; its type is the corresponding index type. See 3.6.2.	105
R.C'Last_Bit	For a component <i>C</i> of a composite, non-array object <i>R</i> :	106
	If the nondefault bit ordering applies to the composite type, and if a <i>component_clause</i> specifies the placement of <i>C</i> , denotes the value given for the <i>last_bit</i> of the <i>component_clause</i> ; otherwise, denotes the offset, from the start of the first of the storage elements occupied by <i>C</i> , of the last bit occupied by <i>C</i> . This offset is measured in bits. The value of this attribute is of the type <i>universal_integer</i> . See 13.5.2.	107/2
S'Last_Valid	For every static discrete subtype <i>S</i> for which there exists at least one value belonging to <i>S</i> that satisfies any predicate of <i>S</i> :	107.1/3
	S'Last_Valid denotes the largest value that belongs to <i>S</i> and satisfies the predicate of <i>S</i> . The value of this attribute is of the type of <i>S</i> . See 3.5.5.	107.2/3
S'Leading_Part	For every subtype <i>S</i> of a floating point type <i>T</i> :	108
	S'Leading_Part denotes a function with the following specification:	109
	<pre> function S'Leading_Part (<i>X</i> : <i>T</i>; <i>Radix_Digits</i> : <i>universal_integer</i>) return <i>T</i> </pre>	110
	Let <i>v</i> be the value $TMachine_Radix^{k-Radix_Digits}$, where <i>k</i> is the normalized exponent of <i>X</i> . The function yields the value	111
	<ul style="list-style-type: none"> • $\lfloor X/v \rfloor \cdot v$, when <i>X</i> is nonnegative and <i>Radix_Digits</i> is positive; • $\lceil X/v \rceil \cdot v$, when <i>X</i> is negative and <i>Radix_Digits</i> is positive. 	112 113
	Constraint_Error is raised when <i>Radix_Digits</i> is zero or negative. A zero result, which can only occur when <i>X</i> is zero, has the sign of <i>X</i> . See A.5.3.	114
A'Length	For a prefix <i>A</i> that is of an array type (after any implicit dereference), or denotes a constrained array subtype:	115/1
	A'Length denotes the number of values of the first index range (zero for a null range); its type is <i>universal_integer</i> . See 3.6.2.	116

- 117/1 **A'Length(N)**
 For a prefix *A* that is of an array type (after any implicit dereference), or denotes a constrained array subtype:
 118 *A'Length(N)* denotes the number of values of the *N*-th index range (zero for a null range); its type is *universal_integer*. See 3.6.2.
- 119 **S'Machine** For every subtype *S* of a floating point type *T*:
 120 *S'Machine* denotes a function with the following specification:
 121

```
function S'Machine (X : T)
  return T
```

 122 If *X* is a machine number of the type *T*, the function yields *X*; otherwise, it yields the value obtained by rounding or truncating *X* to either one of the adjacent machine numbers of the type *T*. *Constraint_Error* is raised if rounding or truncating *X* to the precision of the machine numbers results in a value outside the base range of *S*. A zero result has the sign of *X* when *S'Signed_Zeros* is *True*. See A.5.3.
- 123 **S'Machine_Emax**
 For every subtype *S* of a floating point type *T*:
 124 Yields the largest (most positive) value of *exponent* such that every value expressible in the canonical form (for the type *T*), having a *mantissa* of *T'Machine_Mantissa* digits, is a machine number (see 3.5.7) of the type *T*. This attribute yields a value of the type *universal_integer*. See A.5.3.
- 125 **S'Machine_Emin**
 For every subtype *S* of a floating point type *T*:
 126 Yields the smallest (most negative) value of *exponent* such that every value expressible in the canonical form (for the type *T*), having a *mantissa* of *T'Machine_Mantissa* digits, is a machine number (see 3.5.7) of the type *T*. This attribute yields a value of the type *universal_integer*. See A.5.3.
- 127 **S'Machine_Mantissa**
 For every subtype *S* of a floating point type *T*:
 128 Yields the largest value of *p* such that every value expressible in the canonical form (for the type *T*), having a *p*-digit *mantissa* and an *exponent* between *T'Machine_Emin* and *T'Machine_Emax*, is a machine number (see 3.5.7) of the type *T*. This attribute yields a value of the type *universal_integer*. See A.5.3.
- 129 **S'Machine_Overflows**
 For every subtype *S* of a floating point type *T*:
 130 Yields the value *True* if overflow and divide-by-zero are detected and reported by raising *Constraint_Error* for every predefined operation that yields a result of the type *T*; yields the value *False* otherwise. The value of this attribute is of the predefined type *Boolean*. See A.5.3.
- 131 **S'Machine_Overflows**
 For every subtype *S* of a fixed point type *T*:
 132 Yields the value *True* if overflow and divide-by-zero are detected and reported by raising *Constraint_Error* for every predefined operation that yields a result of the type *T*; yields the value *False* otherwise. The value of this attribute is of the predefined type *Boolean*. See A.5.4.
- 133 **S'Machine_Radix**
 For every subtype *S* of a floating point type *T*:

	Yields the radix of the hardware representation of the type <i>T</i> . The value of this attribute is of the type <i>universal_integer</i> . See A.5.3.	134
S'Machine_Radix	For every subtype <i>S</i> of a fixed point type <i>T</i> :	135
	Yields the radix of the hardware representation of the type <i>T</i> . The value of this attribute is of the type <i>universal_integer</i> . See A.5.4.	136
S'Machine_Rounding	For every subtype <i>S</i> of a floating point type <i>T</i> :	136.1/2
	S'Machine_Rounding denotes a function with the following specification:	136.2/2
	<pre>function S'Machine_Rounding (X : T) return T</pre>	136.3/2
	The function yields the integral value nearest to <i>X</i> . If <i>X</i> lies exactly halfway between two integers, one of those integers is returned, but which of them is returned is unspecified. A zero result has the sign of <i>X</i> when S'Signed_Zeros is True. This function provides access to the rounding behavior which is most efficient on the target processor. See A.5.3.	136.4/2
S'Machine_Rounds	For every subtype <i>S</i> of a floating point type <i>T</i> :	137
	Yields the value True if rounding is performed on inexact results of every predefined operation that yields a result of the type <i>T</i> ; yields the value False otherwise. The value of this attribute is of the predefined type Boolean. See A.5.3.	138
S'Machine_Rounds	For every subtype <i>S</i> of a fixed point type <i>T</i> :	139
	Yields the value True if rounding is performed on inexact results of every predefined operation that yields a result of the type <i>T</i> ; yields the value False otherwise. The value of this attribute is of the predefined type Boolean. See A.5.4.	140
S'Max	For every scalar subtype <i>S</i> :	141
	S'Max denotes a function with the following specification:	142
	<pre>function S'Max(Left, Right : S'Base) return S'Base</pre>	143
	The function returns the greater of the values of the two parameters. See 3.5.	144
S'Max_Alignment_For_Allocation	For every subtype <i>S</i> :	144.1/3
	Denotes the maximum value for Alignment that could be requested by the implementation via Allocate for an access type whose designated subtype is <i>S</i> . The value of this attribute is of type <i>universal_integer</i> . See 13.11.1.	144.2/3
S'Max_Size_In_Storage_Elements	For every subtype <i>S</i> :	145
	Denotes the maximum value for Size_In_Storage_Elements that could be requested by the implementation via Allocate for an access type whose designated subtype is <i>S</i> . The value of this attribute is of type <i>universal_integer</i> . See 13.11.1.	146/3
S'Min	For every scalar subtype <i>S</i> :	147
	S'Min denotes a function with the following specification:	148
	<pre>function S'Min(Left, Right : S'Base) return S'Base</pre>	149
	The function returns the lesser of the values of the two parameters. See 3.5.	150

- 150.1/2 **S'Mod** For every modular subtype *S*:
- 150.2/2 **S'Mod** denotes a function with the following specification:
- 150.3/2

```
function S'Mod (Arg : universal_integer)
return S'Base
```
- 150.4/2 This function returns *Arg mod S'Modulus*, as a value of the type of *S*. See 3.5.4.
- 151 **S'Model** For every subtype *S* of a floating point type *T*:
- 152 **S'Model** denotes a function with the following specification:
- 153

```
function S'Model (X : T)
return T
```
- 154 If the Numerics Annex is not supported, the meaning of this attribute is implementation defined; see G.2.2 for the definition that applies to implementations supporting the Numerics Annex. See A.5.3.
- 155 **S'Model_Emin**
For every subtype *S* of a floating point type *T*:
- 156 If the Numerics Annex is not supported, this attribute yields an implementation defined value that is greater than or equal to the value of *T'Machine_Emin*. See G.2.2 for further requirements that apply to implementations supporting the Numerics Annex. The value of this attribute is of the type *universal_integer*. See A.5.3.
- 157 **S'Model_Epsilon**
For every subtype *S* of a floating point type *T*:
- 158 Yields the value $T'Machine_Radix^{1 - T'Model_Mantissa}$. The value of this attribute is of the type *universal_real*. See A.5.3.
- 159 **S'Model_Mantissa**
For every subtype *S* of a floating point type *T*:
- 160 If the Numerics Annex is not supported, this attribute yields an implementation defined value that is greater than or equal to $\lceil d \cdot \log(10) / \log(T'Machine_Radix) \rceil + 1$, where *d* is the requested decimal precision of *T*, and less than or equal to the value of *T'Machine_Mantissa*. See G.2.2 for further requirements that apply to implementations supporting the Numerics Annex. The value of this attribute is of the type *universal_integer*. See A.5.3.
- 161 **S'Model_Small**
For every subtype *S* of a floating point type *T*:
- 162 Yields the value $T'Machine_Radix^{T'Model_Emin - 1}$. The value of this attribute is of the type *universal_real*. See A.5.3.
- 163 **S'Modulus** For every modular subtype *S*:
- 164 **S'Modulus** yields the modulus of the type of *S*, as a value of the type *universal_integer*. See 3.5.4.
- 164.1/3 **X'Old** For a prefix *X* that denotes an object of a nonlimited type:
- 164.2/3 For each *X'Old* in a postcondition expression that is enabled, a constant is implicitly declared at the beginning of the subprogram or entry. The constant is of the type of *X* and is initialized to the result of evaluating *X* (as an expression) at the point of the constant declaration. The value of *X'Old* in the postcondition expression is the value of this constant; the type of *X'Old* is the type of *X*. These implicit constant declarations occur in an arbitrary order. See 6.1.1.
- 165 **S'Class'Output**
For every subtype *S'Class* of a class-wide type *T'Class*:
- 166 **S'Class'Output** denotes a procedure with the following specification:

	<pre>procedure S'Class'Output (Stream : not null access Ada.Streams.Root_Stream_Type'Class; Item : in T'Class)</pre>	167/2
	First writes the external tag of <i>Item</i> to <i>Stream</i> (by calling <code>String'Output(Stream, Tags.-External_Tag(Item'Tag))</code>) — see 3.9) and then dispatches to the subprogram denoted by the <code>Output</code> attribute of the specific type identified by the tag. <code>Tag_Error</code> is raised if the tag of <i>Item</i> identifies a type declared at an accessibility level deeper than that of <i>S</i> . See 13.13.2.	168/2
S'Output	For every subtype <i>S</i> of a specific type <i>T</i> :	169
	S'Output denotes a procedure with the following specification:	170
	<pre>procedure S'Output (Stream : not null access Ada.Streams.Root_Stream_Type'Class; Item : in T)</pre>	171/2
	S'Output writes the value of <i>Item</i> to <i>Stream</i> , including any bounds or discriminants. See 13.13.2.	172
X'Overlaps_Storage		172.1/3
	For a prefix <i>X</i> that denotes an object:	
	X'Overlaps_Storage denotes a function with the following specification:	172.2/3
	<pre>function X'Overlaps_Storage (Arg : any_type) return Boolean</pre>	172.3/3
	The actual parameter shall be a name that denotes an object. The object denoted by the actual parameter can be of any type. This function evaluates the names of the objects involved and returns <code>True</code> if the representation of the object denoted by the actual parameter shares at least one bit with the representation of the object denoted by <i>X</i> ; otherwise, it returns <code>False</code> . See 13.3.	172.4/3
D'Partition_Id		173/1
	For a prefix <i>D</i> that denotes a library-level declaration, excepting a declaration of or within a declared-pure library unit:	
	Denotes a value of the type <i>universal_integer</i> that identifies the partition in which <i>D</i> was elaborated. If <i>D</i> denotes the declaration of a remote call interface library unit (see E.2.3) the given partition is the one where the body of <i>D</i> was elaborated. See E.1.	174
S'Pos	For every discrete subtype <i>S</i> :	175
	S'Pos denotes a function with the following specification:	176
	<pre>function S'Pos (Arg : S'Base) return universal_integer</pre>	177
	This function returns the position number of the value of <i>Arg</i> , as a value of type <i>universal_integer</i> . See 3.5.5.	178
R.C'Position		179
	For a component <i>C</i> of a composite, non-array object <i>R</i> :	
	If the nondefault bit ordering applies to the composite type, and if a <code>component_clause</code> specifies the placement of <i>C</i> , denotes the value given for the position of the <code>component_clause</code> ; otherwise, denotes the same value as <code>R.C'Address - R'Address</code> . The value of this attribute is of the type <i>universal_integer</i> . See 13.5.2.	180/2
S'Pred	For every scalar subtype <i>S</i> :	181
	S'Pred denotes a function with the following specification:	182
	<pre>function S'Pred (Arg : S'Base) return S'Base</pre>	183

- 184 For an enumeration type, the function returns the value whose position number is one less than that of the value of *Arg*; *Constraint_Error* is raised if there is no such value of the type. For an integer type, the function returns the result of subtracting one from the value of *Arg*. For a fixed point type, the function returns the result of subtracting *small* from the value of *Arg*. For a floating point type, the function returns the machine number (as defined in 3.5.7) immediately below the value of *Arg*; *Constraint_Error* is raised if there is no such machine number. See 3.5.
- 184.1/2 P'Priority For a prefix P that denotes a protected object:
- 184.2/2 Denotes a non-aliased component of the protected object P. This component is of type *System.Any_Priority* and its value is the priority of P. P'Priority denotes a variable if and only if P denotes a variable. A reference to this attribute shall appear only within the body of P. See D.5.2.
- 185/1 A'Range For a prefix A that is of an array type (after any implicit dereference), or denotes a constrained array subtype:
- 186 A'Range is equivalent to the range A'First .. A'Last, except that the prefix A is only evaluated once. See 3.6.2.
- 187 S'Range For every scalar subtype S:
- 188 S'Range is equivalent to the range S'First .. S'Last. See 3.5.
- 189/1 A'Range(N)
- For a prefix A that is of an array type (after any implicit dereference), or denotes a constrained array subtype:
- 190 A'Range(N) is equivalent to the range A'First(N) .. A'Last(N), except that the prefix A is only evaluated once. See 3.6.2.
- 191 S'Class'Read
- For every subtype S'Class of a class-wide type T'Class:
- 192 S'Class'Read denotes a procedure with the following specification:
- 193/2

```
procedure S'Class'Read(  
    Stream : not null access Ada.Streams.Root_Stream_Type'Class;  
    Item : out T'Class)
```
- 194 Dispatches to the subprogram denoted by the Read attribute of the specific type identified by the tag of Item. See 13.13.2.
- 195 S'Read For every subtype S of a specific type T:
- 196 S'Read denotes a procedure with the following specification:
- 197/2

```
procedure S'Read(  
    Stream : not null access Ada.Streams.Root_Stream_Type'Class;  
    Item : out T)
```
- 198 S'Read reads the value of *Item* from *Stream*. See 13.13.2.
- 199 S'Remainder
- For every subtype S of a floating point type T:
- 200 S'Remainder denotes a function with the following specification:
- 201

```
function S'Remainder (X, Y : T)  
    return T
```
- 202 For nonzero Y, let *v* be the value $X - n \cdot Y$, where *n* is the integer nearest to the exact value of X/Y ; if $|n - X/Y| = 1/2$, then *n* is chosen to be even. If *v* is a machine number of the type T, the function yields *v*; otherwise, it yields zero. *Constraint_Error* is raised if Y is zero. A zero result has the sign of X when S'Signed_Zeros is True. See A.5.3.

F'Result	For a prefix <i>F</i> that denotes a function declaration:	202.1/3
	Within a postcondition expression for function <i>F</i> , denotes the result object of the function. The type of this attribute is that of the function result except within a Post'Class postcondition expression for a function with a controlling result or with a controlling access result. For a controlling result, the type of the attribute is <i>T</i> Class, where <i>T</i> is the function result type. For a controlling access result, the type of the attribute is an anonymous access type whose designated type is <i>T</i> Class, where <i>T</i> is the designated type of the function result type. See 6.1.1.	202.2/3
S'Round	For every decimal fixed point subtype <i>S</i> :	203
	S'Round denotes a function with the following specification:	204
	<pre>function S'Round (X : universal_real) return S'Base</pre>	205
	The function returns the value obtained by rounding <i>X</i> (away from 0, if <i>X</i> is midway between two values of the type of <i>S</i>). See 3.5.10.	206
S'Rounding	For every subtype <i>S</i> of a floating point type <i>T</i> :	207
	S'Rounding denotes a function with the following specification:	208
	<pre>function S'Rounding (X : T) return T</pre>	209
	The function yields the integral value nearest to <i>X</i> , rounding away from zero if <i>X</i> lies exactly halfway between two integers. A zero result has the sign of <i>X</i> when S'Signed_Zeros is True. See A.5.3.	210
S'Safe_First	For every subtype <i>S</i> of a floating point type <i>T</i> :	211
	Yields the lower bound of the safe range (see 3.5.7) of the type <i>T</i> . If the Numerics Annex is not supported, the value of this attribute is implementation defined; see G.2.2 for the definition that applies to implementations supporting the Numerics Annex. The value of this attribute is of the type <i>universal_real</i> . See A.5.3.	212
S'Safe_Last	For every subtype <i>S</i> of a floating point type <i>T</i> :	213
	Yields the upper bound of the safe range (see 3.5.7) of the type <i>T</i> . If the Numerics Annex is not supported, the value of this attribute is implementation defined; see G.2.2 for the definition that applies to implementations supporting the Numerics Annex. The value of this attribute is of the type <i>universal_real</i> . See A.5.3.	214
S'Scale	For every decimal fixed point subtype <i>S</i> :	215
	S'Scale denotes the <i>scale</i> of the subtype <i>S</i> , defined as the value <i>N</i> such that S'Delta = 10.0**(- <i>N</i>). The scale indicates the position of the point relative to the rightmost significant digits of values of subtype <i>S</i> . The value of this attribute is of the type <i>universal_integer</i> . See 3.5.10.	216
S'Scaling	For every subtype <i>S</i> of a floating point type <i>T</i> :	217
	S'Scaling denotes a function with the following specification:	218
	<pre>function S'Scaling (X : T; Adjustment : universal_integer) return T</pre>	219
	Let <i>v</i> be the value $X \cdot TMachine_Radix^{Adjustment}$. If <i>v</i> is a machine number of the type <i>T</i> , or if $ v \geq TModel_Small$, the function yields <i>v</i> ; otherwise, it yields either one of the machine numbers of the type <i>T</i> adjacent to <i>v</i> . Constraint_Error is optionally raised if <i>v</i> is outside the base range of <i>S</i> . A zero result has the sign of <i>X</i> when S'Signed_Zeros is True. See A.5.3.	220

221	S'Signed_Zeros	For every subtype S of a floating point type <i>T</i> :
222		Yields the value True if the hardware representation for the type <i>T</i> has the capability of representing both positively and negatively signed zeros, these being generated and used by the predefined operations of the type <i>T</i> as specified in IEC 559:1989; yields the value False otherwise. The value of this attribute is of the predefined type Boolean. See A.5.3.
223	S'Size	For every subtype S:
224		If S is definite, denotes the size (in bits) that the implementation would choose for the following objects of subtype S:
225		• A record component of subtype S when the record type is packed.
226		• The formal parameter of an instance of Unchecked_Conversion that converts from subtype S to some other subtype.
227		If S is indefinite, the meaning is implementation defined. The value of this attribute is of the type <i>universal_integer</i> . See 13.3.
228/1	X'Size	For a prefix X that denotes an object:
229		Denotes the size in bits of the representation of the object. The value of this attribute is of the type <i>universal_integer</i> . See 13.3.
230	S'Small	For every fixed point subtype S:
231		S'Small denotes the <i>small</i> of the type of S. The value of this attribute is of the type <i>universal_real</i> . See 3.5.10.
232	S'Storage_Pool	For every access-to-object subtype S:
233		Denotes the storage pool of the type of S. The type of this attribute is Root_Storage_Pool'Class. See 13.11.
234	S'Storage_Size	For every access-to-object subtype S:
235		Yields the result of calling Storage_Size(S'Storage_Pool), which is intended to be a measure of the number of storage elements reserved for the pool. The type of this attribute is <i>universal_integer</i> . See 13.11.
236/1	T'Storage_Size	For a prefix T that denotes a task object (after any implicit dereference):
237		Denotes the number of storage elements reserved for the task. The value of this attribute is of the type <i>universal_integer</i> . The Storage_Size includes the size of the task's stack, if any. The language does not specify whether or not it includes other storage associated with the task (such as the “task control block” used by some implementations.) See 13.3.
237.1/3	S'Stream_Size	For every subtype S of an elementary type <i>T</i> :
237.2/3		Denotes the number of bits read from or written to a stream by the default implementations of S'Read and S'Write. Hence, the number of stream elements required per item of elementary type <i>T</i> is:
237.3/2		<i>T'Stream_Size</i> / Ada.Streams.Stream_Element'Size
237.4/2		The value of this attribute is of type <i>universal_integer</i> and is a multiple of Stream_Element'Size. See 13.13.2.
238	S'Succ	For every scalar subtype S:

S'Succ	denotes a function with the following specification:	239
	<pre>function S'Succ (Arg : S'Base) return S'Base</pre>	240
	For an enumeration type, the function returns the value whose position number is one more than that of the value of <i>Arg</i> ; <i>Constraint_Error</i> is raised if there is no such value of the type. For an integer type, the function returns the result of adding one to the value of <i>Arg</i> . For a fixed point type, the function returns the result of adding <i>small</i> to the value of <i>Arg</i> . For a floating point type, the function returns the machine number (as defined in 3.5.7) immediately above the value of <i>Arg</i> ; <i>Constraint_Error</i> is raised if there is no such machine number. See 3.5.	241
S'Tag	For every subtype <i>S</i> of a tagged type <i>T</i> (specific or class-wide):	242
	S'Tag denotes the tag of the type <i>T</i> (or if <i>T</i> is class-wide, the tag of the root type of the corresponding class). The value of this attribute is of type <i>Tag</i> . See 3.9.	243
X'Tag	For a prefix <i>X</i> that is of a class-wide tagged type (after any implicit dereference):	244
	X'Tag denotes the tag of <i>X</i> . The value of this attribute is of type <i>Tag</i> . See 3.9.	245
T'Terminated	For a prefix <i>T</i> that is of a task type (after any implicit dereference):	246
	Yields the value <i>True</i> if the task denoted by <i>T</i> is terminated, and <i>False</i> otherwise. The value of this attribute is of the predefined type <i>Boolean</i> . See 9.9.	247
S'Truncation	For every subtype <i>S</i> of a floating point type <i>T</i> :	248
	S'Truncation denotes a function with the following specification:	249
	<pre>function S'Truncation (X : T) return T</pre>	250
	The function yields the value $\lceil X \rceil$ when <i>X</i> is negative, and $\lfloor X \rfloor$ otherwise. A zero result has the sign of <i>X</i> when <i>S'Signed_Zeros</i> is <i>True</i> . See A.5.3.	251
S'Unbiased_Rounding	For every subtype <i>S</i> of a floating point type <i>T</i> :	252
	S'Unbiased_Rounding denotes a function with the following specification:	253
	<pre>function S'Unbiased_Rounding (X : T) return T</pre>	254
	The function yields the integral value nearest to <i>X</i> , rounding toward the even integer if <i>X</i> lies exactly halfway between two integers. A zero result has the sign of <i>X</i> when <i>S'Signed_Zeros</i> is <i>True</i> . See A.5.3.	255
X'Unchecked_Access	For a prefix <i>X</i> that denotes an aliased view of an object:	256
	All rules and semantics that apply to <i>X'Access</i> (see 3.10.2) apply also to <i>X'Unchecked_Access</i> , except that, for the purposes of accessibility rules and checks, it is as if <i>X</i> were declared immediately within a library package. See 13.10.	257
S'Val	For every discrete subtype <i>S</i> :	258
	S'Val denotes a function with the following specification:	259
	<pre>function S'Val (Arg : universal_integer) return S'Base</pre>	260
	This function returns a value of the type of <i>S</i> whose position number equals the value of <i>Arg</i> . See 3.5.5.	261

- 262 X'Valid For a prefix X that denotes a scalar object (after any implicit dereference):
- 263/3 Yields True if and only if the object denoted by X is normal, has a valid representation, and the predicate of the nominal subtype of X evaluates to True. The value of this attribute is of the predefined type Boolean. See 13.9.2.
- 264 S'Value For every scalar subtype S:
- 265 S'Value denotes a function with the following specification:
- 266

```
function S'Value(Arg : String)
return S'Base
```
- 267 This function returns a value given an image of the value as a String, ignoring any leading or trailing spaces. See 3.5.
- 268/1 P'Version For a prefix P that statically denotes a program unit:
- 269 Yields a value of the predefined type String that identifies the version of the compilation unit that contains the declaration of the program unit. See E.3.
- 270 S'Wide_Image For every scalar subtype S:
- 271 S'Wide_Image denotes a function with the following specification:
- 272

```
function S'Wide_Image(Arg : S'Base)
return Wide_String
```
- 273/3 The function returns an image of the value of Arg as a Wide_String. See 3.5.
- 274 S'Wide_Value For every scalar subtype S:
- 275 S'Wide_Value denotes a function with the following specification:
- 276

```
function S'Wide_Value(Arg : Wide_String)
return S'Base
```
- 277 This function returns a value given an image of the value as a Wide_String, ignoring any leading or trailing spaces. See 3.5.
- 277.1/2 S'Wide_Wide_Image For every scalar subtype S:
- 277.2/2 S'Wide_Wide_Image denotes a function with the following specification:
- 277.3/2

```
function S'Wide_Wide_Image(Arg : S'Base)
return Wide_Wide_String
```
- 277.4/2 The function returns an *image* of the value of Arg, that is, a sequence of characters representing the value in display form. See 3.5.
- 277.5/2 S'Wide_Wide_Value For every scalar subtype S:
- 277.6/2 S'Wide_Wide_Value denotes a function with the following specification:
- 277.7/2

```
function S'Wide_Wide_Value(Arg : Wide_Wide_String)
return S'Base
```
- 277.8/2 This function returns a value given an image of the value as a Wide_Wide_String, ignoring any leading or trailing spaces. See 3.5.
- 277.9/2 S'Wide_Wide_Width For every scalar subtype S:
- 277.10/2 S'Wide_Wide_Width denotes the maximum length of a Wide_Wide_String returned by S'Wide_Wide_Image over all values of the subtype S. It denotes zero for a subtype that has a null range. Its type is *universal_integer*. See 3.5.

S'Wide_Width	For every scalar subtype S: S'Wide_Width denotes the maximum length of a Wide_String returned by S'Wide_Image over all values of the subtype S. It denotes zero for a subtype that has a null range. Its type is <i>universal_integer</i> . See 3.5.	278 279
S'Width	For every scalar subtype S: S'Width denotes the maximum length of a String returned by S'Image over all values of the subtype S. It denotes zero for a subtype that has a null range. Its type is <i>universal_integer</i> . See 3.5.	280 281
S'Class'Write	For every subtype S'Class of a class-wide type T'Class: S'Class'Write denotes a procedure with the following specification:	282 283
	<pre>procedure S'Class'Write(Stream : not null access Ada.Streams.Root_Stream_Type'Class; Item : in T'Class)</pre>	284/2
	Dispatches to the subprogram denoted by the Write attribute of the specific type identified by the tag of Item. See 13.13.2.	285
S'Write	For every subtype S of a specific type T: S'Write denotes a procedure with the following specification:	286 287
	<pre>procedure S'Write(Stream : not null access Ada.Streams.Root_Stream_Type'Class; Item : in T)</pre>	288/2
	S'Write writes the value of <i>Item</i> to <i>Stream</i> . See 13.13.2.	289

Annex L

(informative)

Language-Defined Pragmas

This Annex summarizes the definitions given elsewhere of the language-defined pragmas.	1
pragma All_Calls_Remote(<i>library_unit_name</i>); — See E.2.3.	2
pragma Assert([Check =>] <i>boolean_expression</i> [, [Message =>] <i>string_expression</i>]); — See 11.4.2.	2.1/2
pragma Assertion_Policy(<i>policy_identifier</i>); — See 11.4.2.	2.2/2
pragma Assertion_Policy(<i>assertion_aspect_mark</i> => <i>policy_identifier</i> {, <i>assertion_aspect_mark</i> => <i>policy_identifier</i> }); — See 11.4.2.	2.3/3
<i>This paragraph was deleted.</i>	3/3
pragma Asynchronous (<i>local_name</i>); — See J.15.13.	3.1/3
<i>This paragraph was deleted.</i>	4/3
pragma Atomic (<i>local_name</i>); — See J.15.8.	4.1/3
<i>This paragraph was deleted.</i>	5/3
pragma Atomic_Components (<i>array_local_name</i>); — See J.15.8.	5.1/3
<i>This paragraph was deleted.</i>	6/3
pragma Attach_Handler (<i>handler_name</i> , <i>expression</i>); — See J.15.7.	6.1/3
<i>This paragraph was deleted.</i>	7/3
<i>This paragraph was deleted.</i>	8/3
pragma Convention([Convention =>] <i>convention_identifier</i> , [Entity =>] <i>local_name</i>); — See J.15.5.	8.1/3
pragma CPU (<i>expression</i>); — See J.15.9.	8.2/3
pragma Default_Storage_Pool (<i>storage_pool_indicator</i>); — See 13.11.3.	8.3/3
pragma Detect_Blocking; — See H.5.	8.4/2
pragma Discard_Names([On =>] <i>local_name</i>); — See C.5.	9
pragma Dispatching_Domain (<i>expression</i>); — See J.15.10.	9.1/3
pragma Elaborate(<i>library_unit_name</i> {, <i>library_unit_name</i> }); — See 10.2.1.	10
pragma Elaborate_All(<i>library_unit_name</i> {, <i>library_unit_name</i> }); — See 10.2.1.	11
pragma Elaborate_Body(<i>library_unit_name</i>); — See 10.2.1.	12
<i>This paragraph was deleted.</i>	13/3
pragma Export([Convention =>] <i>convention_identifier</i> , [Entity =>] <i>local_name</i> [, [External_Name =>] <i>external_name_string_expression</i>] [, [Link_Name =>] <i>link_name_string_expression</i>]); — See J.15.5.	13.1/3
<i>This paragraph was deleted.</i>	14/3

Annex M

(informative)

Summary of Documentation Requirements

{AI05-0299-1} The Ada language allows for certain target machine dependences in a controlled manner. Each Ada implementation must document many characteristics and properties of the target system. This International Standard contains specific documentation requirements. In addition, many characteristics that require documentation are identified throughout this International Standard as being implementation defined. Finally, this International Standard requires documentation of whether implementation advice is followed. The following subclauses provide summaries of these documentation requirements. 1/3

M.1 Specific Documentation Requirements

In addition to implementation-defined characteristics, each Ada implementation must document various properties of the implementation: 1/2

- Ramification:** Most of the items in this list require documentation only for implementations that conform to Specialized Needs Annexes. 1.a/2
- The behavior of implementations in implementation-defined situations shall be documented — see M.2, “Implementation-Defined Characteristics” for a listing. See 1.1.3(19). 2/2
 - The set of values that a user-defined Allocate procedure needs to accept for the Alignment parameter. How the standard storage pool is chosen, and how storage is allocated by standard storage pools. See 13.11(22). 3/2
 - The algorithm used for random number generation, including a description of its period. See A.5.2(44). 4/2
 - The minimum time interval between calls to the time-dependent Reset procedure that is guaranteed to initiate different random number sequences. See A.5.2(45). 5/2
 - The conditions under which `Io_Exceptions.Name_Error`, `Io_Exceptions.Use_Error`, and `Io_Exceptions.Device_Error` are propagated. See A.13(15). 6/2
 - The behavior of package `Environment_Variables` when environment variables are changed by external mechanisms. See A.17(30/2). 7/2
 - The overhead of calling machine-code or intrinsic subprograms. See C.1(6). 8/2
 - The types and attributes used in machine code insertions. See C.1(7). 9/2
 - The subprogram calling conventions for all supported convention identifiers. See C.1(8/3). 10/2
 - The mapping between the `Link_Name` or Ada designator and the external link name. See C.1(9). 11/2
 - The treatment of interrupts. See C.3(22). 12/2
 - The metrics for interrupt handlers. See C.3.1(16). 13/2
 - If the `Ceiling_Locking` policy is in effect, the default ceiling priority for a protected object that specifies an interrupt handler aspect. See C.3.2(24/3). 14/3
 - Any circumstances when the elaboration of a preelaborated package causes code to be executed. See C.4(12). 15/2
 - Whether a partition can be restarted without reloading. See C.4(13). 16/2
 - The effect of calling `Current_Task` from an entry body or interrupt handler. See C.7.1(19). 17/2

- 18/2 • For package `Task_Attributes`, limits on the number and size of task attributes, and how to configure any limits. See C.7.2(19).
- 19/2 • The metrics for the `Task_Attributes` package. See C.7.2(27).
- 20/2 • The details of the configuration used to generate the values of all metrics. See D(2).
- 21/2 • The maximum priority inversion a user task can experience from the implementation. See D.2.3(12/2).
- 22/2 • The amount of time that a task can be preempted for processing on behalf of lower-priority tasks. See D.2.3(13/2).
- 23/2 • The quantum values supported for round robin dispatching. See D.2.5(16/2).
- 24/2 • The accuracy of the detection of the exhaustion of the budget of a task for round robin dispatching. See D.2.5(17/2).
- 25/2 • Any conditions that cause the completion of the setting of the deadline of a task to be delayed for a multiprocessor. See D.2.6(32/2).
- 26/2 • Any conditions that cause the completion of the setting of the priority of a task to be delayed for a multiprocessor. See D.5.1(12.1/2).
- 27/2 • The metrics for `Set_Priority`. See D.5.1(14).
- 28/2 • The metrics for setting the priority of a protected object. See D.5.2(10).
- 29/2 • On a multiprocessor, any conditions that cause the completion of an aborted construct to be delayed later than what is specified for a single processor. See D.6(3).
- 30/2 • The metrics for aborts. See D.6(8).
- 31/2 • The values of `Time_First`, `Time_Last`, `Time_Span_First`, `Time_Span_Last`, `Time_Span_Unit`, and `Tick` for package `Real_Time`. See D.8(33).
- 32/2 • The properties of the underlying time base used in package `Real_Time`. See D.8(34).
- 33/2 • Any synchronization of package `Real_Time` with external time references. See D.8(35).
- 34/2 • Any aspects of the external environment that could interfere with package `Real_Time`. See D.8(36/3).
- 35/2 • The metrics for package `Real_Time`. See D.8(45).
- 36/2 • The minimum value of the delay expression of a `delay_relative_statement` that causes a task to actually be blocked. See D.9(7).
- 37/2 • The minimum difference between the value of the delay expression of a `delay_until_statement` and the value of `Real_Time.Clock`, that causes the task to actually be blocked. See D.9(8).
- 38/2 • The metrics for delay statements. See D.9(13).
- 39/2 • The upper bound on the duration of interrupt blocking caused by the implementation. See D.12(5).
- 40/2 • The metrics for entry-less protected objects. See D.12(12).
- 41/2 • The values of `CPU_Time_First`, `CPU_Time_Last`, `CPU_Time_Unit`, and `CPU_Tick` of package `Execution_Time`. See D.14(21/2).
- 42/3 • The properties of the mechanism used to implement package `Execution_Time`, including the values of the constants defined in the package. See D.14(22/2).
- 43/2 • The metrics for execution time. See D.14(27).
- 44/2 • The metrics for timing events. See D.15(24).

- The processor(s) on which the clock interrupt is handled; the processors on which each Interrupt_Id can be handled. See D.16.1(32). 44.1/3
- Whether the RPC-receiver is invoked from concurrent tasks, and if so, the number of such tasks. See E.5(25). 45/2
- Any techniques used to reduce cancellation errors in Numerics.Generic_Real_Arrays shall be documented. See G.3.1(86/2). 46/2
- Any techniques used to reduce cancellation errors in Numerics.Generic_Complex_Arrays shall be documented. See G.3.2(155/2). 47/2
- If a pragma Normalize_Scalars applies, the implicit initial values of scalar subtypes shall be documented. Such a value should be an invalid representation when possible; any cases when it is not shall be documented. See H.1(5/2). 48/2
- The range of effects for each bounded error and each unspecified effect. If the effects of a given erroneous construct are constrained, the constraints shall be documented. See H.2(1). 49/2
- For each inspection point, a mapping between each inspectable object and the machine resources where the object's value can be obtained shall be provided. See H.3.2(8). 50/2
- If a pragma Restrictions(No_Exceptions) is specified, the effects of all constructs where language-defined checks are still performed. See H.4(25). 51/2
- The interrupts to which a task entry may be attached. See J.7.1(12). 52/2
- The type of entry call invoked for an interrupt entry. See J.7.1(13). 53/2

M.2 Implementation-Defined Characteristics

The Ada language allows for certain machine dependences in a controlled manner. Each Ada implementation must document all implementation-defined characteristics: 1/2

- **Ramification:** It need not document unspecified characteristics. 1.a
- Some of the items in this list require documentation only for implementations that conform to Specialized Needs Annexes. 1.b
- Whether or not each recommendation given in Implementation Advice is followed — see M.3, “Implementation Advice” for a listing. See 1.1.2(37). 2/2
- Capacity limitations of the implementation. See 1.1.3(3). 3
- Variations from the standard that are impractical to avoid given the implementation's execution environment. See 1.1.3(6). 4
- Which code_statements cause external interactions. See 1.1.3(10). 5
- The coded representation for the text of an Ada program. See 2.1(4/3). 6
- The semantics of an Ada program whose text is not in Normalization Form KC. See 2.1(4.1/3). 6.1/2
- *This paragraph was deleted.* 7/2
- The representation for an end of line. See 2.2(2/3). 8
- Maximum supported line length and lexical element length. See 2.2(14). 9
- Implementation-defined pragmas. See 2.8(14). 10
- Effect of pragma Optimize. See 2.8(27). 11
- The sequence of characters of the value returned by S'Wide_Image when some of the graphic characters of S'Wide_Wide_Image are not defined in Wide_Character. See 3.5(30/3). 11.1/2

- 12/2 • The sequence of characters of the value returned by S'Image when some of the graphic characters of S'Wide_Wide_Image are not defined in Character. See 3.5(37/3).
- 13 • The predefined integer types declared in Standard. See 3.5.4(25).
- 14 • Any nonstandard integer types and the operators defined for them. See 3.5.4(26).
- 15 • Any nonstandard real types and the operators defined for them. See 3.5.6(8).
- 16 • What combinations of requested decimal precision and range are supported for floating point types. See 3.5.7(7).
- 17 • The predefined floating point types declared in Standard. See 3.5.7(16).
- 18 • The *small* of an ordinary fixed point type. See 3.5.9(8/2).
- 19 • What combinations of *small*, range, and *digits* are supported for fixed point types. See 3.5.9(10).
- 20/2 • The result of Tags.Wide_Wide_Expanded_Name for types declared within an unnamed block_statement. See 3.9(10).
- 20.1/2 • The sequence of characters of the value returned by Tags.Expanded_Name (respectively, Tags.Wide_Expanded_Name) when some of the graphic characters of Tags.Wide_Wide_Expanded_Name are not defined in Character (respectively, Wide_Character). See 3.9(10.1/2).
- 21 • Implementation-defined attributes. See 4.1.4(12/1).
- 21.1/2 • Rounding of real static expressions which are exactly half-way between two machine numbers. See 4.9(38/2).
- 22 • Any implementation-defined time types. See 9.6(6/3).
- 23 • The time base associated with relative delays. See 9.6(20).
- 24 • The time base of the type Calendar.Time. See 9.6(23).
- 25/2 • The time zone used for package Calendar operations. See 9.6(24/2).
- 26 • Any limit on delay_until_statements of select_statements. See 9.6(29).
- 26.1/2 • The result of Calendar.Formatting.Image if its argument represents more than 100 hours. See 9.6.1(86/2).
- 27/3 • *This paragraph was deleted.*
- 28 • The representation for a compilation. See 10.1(2).
- 29 • Any restrictions on compilations that contain multiple compilation_units. See 10.1(4).
- 30 • The mechanisms for creating an environment and for adding and replacing compilation units. See 10.1.4(3/2).
- 30.1/2 • The mechanisms for adding a compilation unit mentioned in a limited_with_clause to an environment. See 10.1.4(3).
- 31 • The manner of explicitly assigning library units to a partition. See 10.2(2).
- 32 • The implementation-defined means, if any, of specifying which compilation units are needed by a given compilation unit. See 10.2(2).
- 33 • The manner of designating the main subprogram of a partition. See 10.2(7).
- 34 • The order of elaboration of library_items. See 10.2(18).
- 35 • Parameter passing and function return for the main subprogram. See 10.2(21).
- 36 • The mechanisms for building and running partitions. See 10.2(24).

- The details of program execution, including program termination. See 10.2(25). 37
- The semantics of any nonactive partitions supported by the implementation. See 10.2(28/3). 38
- The information returned by `Exception_Message`. See 11.4.1(10.1/3). 39
- The result of `Exceptions.Wide_Wide_Exception_Name` for exceptions declared within an unnamed `block_statement`. See 11.4.1(12). 40/2
- The sequence of characters of the value returned by `Exceptions.Exception_Name` (respectively, `Exceptions.Wide_Exception_Name`) when some of the graphic characters of `Exceptions.Wide_Wide_Exception_Name` are not defined in `Character` (respectively, `Wide_Character`). See 11.4.1(12.1/2). 40.1/2
- The information returned by `Exception_Information`. See 11.4.1(13/2). 41
- Implementation-defined *policy_identifiers* and *assertion_aspect_marks* allowed in a `pragma Assertion_Policy`. See 11.4.2(9/3). 41.1/3
- The default assertion policy. See 11.4.2(10). 41.2/2
- Implementation-defined check names. See 11.5(27). 42
- Existence and meaning of second parameter of `pragma Unsuppress`. See 11.5(27.1/2). 42.1/2
- The cases that cause conflicts between the representation of the ancestors of a `type_declaration`. See 13.1(13.1/3). 42.2/2
- The interpretation of each representation aspect. See 13.1(20). 43/3
- Any restrictions placed upon the specification of representation aspects. See 13.1(20). 44/3
- Implementation-defined aspects, including the syntax for specifying such aspects and the legality rules for such aspects. See 13.1.1(38). 44.1/3
- The set of machine scalars. See 13.3(8.1/3). 44.2/2
- The meaning of `Size` for indefinite subtypes. See 13.3(48). 45
- The default external representation for a type tag. See 13.3(75/3). 46
- What determines whether a compilation unit is the same in two different partitions. See 13.3(76). 47
- Implementation-defined components. See 13.5.1(15). 48
- If `Word_Size = Storage_Unit`, the default bit ordering. See 13.5.3(5). 49
- The contents of the visible part of package `System`. See 13.7(2). 50/2
- The range of `Storage_Elements.Storage_Offset`, the modulus of `Storage_Elements.Storage_Element`, and the declaration of `Storage_Elements.Integer_Address..`. See 13.7.1(11). 50.1/2
- The contents of the visible part of package `System.Machine_Code`, and the meaning of `code_statements`. See 13.8(7). 51
- The result of unchecked conversion for instances with scalar result types whose result is not defined by the language. See 13.9(11). 51.1/2
- The effect of unchecked conversion for instances with nonscalar result types whose effect is not defined by the language. See 13.9(11). 52/2
- *This paragraph was deleted.* 53/2
- Whether or not the implementation provides user-accessible names for the standard pool type(s). See 13.11(17). 54

- 55/2 • The meaning of `Storage_Size` when neither the `Storage_Size` nor the `Storage_Pool` is specified for an access type. See 13.11(18).
- 56/2 • *This paragraph was deleted.*
- 57/3 • *This paragraph was deleted.*
- 57.1/3 • Implementation-defined restrictions allowed in a `pragma Restrictions`. See 13.12(8.7/3).
- 58 • The consequences of violating limitations on `Restrictions pragmas`. See 13.12(9).
- 58.1/3 • Implementation-defined usage profiles allowed in a `pragma Profile`. See 13.12(15).
- 59/2 • The contents of the stream elements read and written by the `Read` and `Write` attributes of elementary types. See 13.13.2(9).
- 60 • The names and characteristics of the numeric subtypes declared in the visible part of package `Standard`. See A.1(3).
- 60.1/2 • The values returned by `Strings.Hash`. See A.4.9(3/2).
- 61 • The accuracy actually achieved by the elementary functions. See A.5.1(1).
- 62 • The sign of a zero result from some of the operators or functions in `Numerics.Generic_Elementary_Functions`, when `Float_Type'Signed_Zeros` is `True`. See A.5.1(46).
- 63 • The value of `Numerics.Float_Random.Max_Image_Width`. See A.5.2(27).
- 64 • The value of `Numerics.Discrete_Random.Max_Image_Width`. See A.5.2(27).
- 65/2 • *This paragraph was deleted.*
- 66 • The string representation of a random number generator's state. See A.5.2(38).
- 67/2 • *This paragraph was deleted.*
- 68 • The values of the `Model_Mantissa`, `Model_Emin`, `Model_Epsilon`, `Model`, `Safe_First`, and `Safe_Last` attributes, if the `Numerics Annex` is not supported. See A.5.3(72).
- 69/2 • *This paragraph was deleted.*
- 70 • The value of `Buffer_Size` in `Storage_IO`. See A.9(10).
- 71/2 • The external files associated with the standard input, standard output, and standard error files. See A.10(5).
- 72 • The accuracy of the value produced by `Put`. See A.10.9(36).
- 72.1/1 • Current size for a stream file for which positioning is not supported. See A.12.1(1.1/1).
- 73/2 • The meaning of `Argument_Count`, `Argument`, and `Command_Name` for package `Command_Line`. The bounds of type `Command_Line.Exit_Status`. See A.15(1).
- 73.1/2 • The interpretation of file names and directory names. See A.16(46/2).
- 73.2/2 • The maximum value for a file size in `Directories`. See A.16(87/2).
- 73.3/2 • The result for `Directories.Size` for a directory or special file See A.16(93/2).
- 73.4/2 • The result for `Directories.Modification_Time` for a directory or special file. See A.16(95/2).
- 73.5/2 • The interpretation of a nonnull search pattern in `Directories`. See A.16(104/3).
- 73.6/2 • The results of a `Directories` search if the contents of the directory are altered while a search is in progress. See A.16(110/3).
- 73.7/2 • The definition and meaning of an environment variable. See A.17(1/2).
- 73.8/2 • The circumstances where an environment variable cannot be defined. See A.17(16/2).

- Environment names for which Set has the effect of Clear. See A.17(17/2). 73.9/2
- The value of Containers.Hash_Type'Modulus. The value of Containers.Count_Type'Last. See A.18.1(7/2). 73.10/2
- Implementation-defined convention names. See B.1(11/3). 74
- The meaning of link names. See B.1(36). 75
- The manner of choosing link names when neither the link name nor the address of an imported or exported entity is specified. See B.1(36). 76
- The effect of pragma Linker_Options. See B.1(37). 77
- The contents of the visible part of package Interfaces and its language-defined descendants. See B.2(1). 78
- Implementation-defined children of package Interfaces. See B.2(11). 79/2
- The definitions of certain types and constants in Interfaces.C. See B.3(41). 79.1/2
- The types Floating, Long_Floating, Binary, Long_Binary, Decimal_Element, and COBOL_Character; and the initializations of the variables Ada_To_COBOL and COBOL_To_Ada, in Interfaces.COBOLE. See B.4(50). 80/1
- The types Fortran_Integer, Real, Double_Precision, and Character_Set in Interfaces.Fortran. See B.5(17). 80.1/1
- Implementation-defined intrinsic subprograms. See C.1(1/3). 81/2
- *This paragraph was deleted.* 82/2
- *This paragraph was deleted.* 83/2
- Any restrictions on a protected procedure or its containing type when an aspect Attach_handler or Interrupt_Handler is specified. See C.3.1(17). 83.1/3
- Any other forms of interrupt handler supported by the Attach_Handler and Interrupt_Handler aspects. See C.3.1(19). 83.2/3
- *This paragraph was deleted.* 84/2
- The semantics of pragma Discard_Names. See C.5(7). 85
- The result of the Task_Identification.Image attribute. See C.7.1(7). 86
- The value of Current_Task when in a protected entry, interrupt handler, or finalization of a task attribute. See C.7.1(17/3). 87/2
- *This paragraph was deleted.* 88/2
- Granularity of locking for Task_Attributes. See C.7.2(16/1). 88.1/1
- *This paragraph was deleted.* 89/2
- *This paragraph was deleted.* 90/2
- The declarations of Any_Priority and Priority. See D.1(11). 91
- Implementation-defined execution resources. See D.1(15). 92
- Whether, on a multiprocessor, a task that is waiting for access to a protected object keeps its processor busy. See D.2.1(3). 93
- The effect of implementation-defined execution resources on task dispatching. See D.2.1(9/2). 94/2
- *This paragraph was deleted.* 95/2
- *This paragraph was deleted.* 96/2

- 97/2 • Implementation defined task dispatching policies. See D.2.2(19).
- 97.1/2 • The value of `Default_Quantum` in `Dispatching.Round_Robin`. See D.2.5(4).
- 98 • Implementation-defined *policy_identifiers* allowed in a `pragma Locking_Policy`. See D.3(4).
- 98.1/2 • The locking policy if no `Locking_Policy` pragma applies to any unit of a partition. See D.3(6).
- 99 • Default ceiling priorities. See D.3(10/3).
- 100 • The ceiling of any protected object used internally by the implementation. See D.3(16).
- 101 • Implementation-defined queuing policies. See D.4(1/3).
- 102/2 • *This paragraph was deleted.*
- 103 • Any operations that implicitly require heap storage allocation. See D.7(8).
- 103.1/2 • When restriction `No_Task_Termination` applies to a partition, what happens when a task terminates. See D.7(15.1/2).
- 103.2/2 • The behavior when restriction `Max_Storage_At_Blocking` is violated. See D.7(17/1).
- 103.3/2 • The behavior when restriction `Max_Asynchronous_Select_Nesting` is violated. See D.7(18/1).
- 103.4/2 • The behavior when restriction `Max_Tasks` is violated. See D.7(19).
- 104/2 • Whether the use of pragma `Restrictions` results in a reduction in program code or data size or execution time. See D.7(20).
- 105/2 • *This paragraph was deleted.*
- 106/2 • *This paragraph was deleted.*
- 106.1/3 • The value of `Barrier_Limit'Last` in `Synchronous_Barriers`. See D.10.1(4/3).
- 106.2/3 • When an aborted task that is waiting on a `Synchronous_Barrier` is aborted. See D.10.1(13/3).
- 107/2 • *This paragraph was deleted.*
- 107.1/3 • The processor on which a task with a CPU value of a `Not_A_Specific_CPU` will execute when the Ravenscar profile is in effect. See D.13(8).
- 107.2/3 • The value of `Min_Handler_Ceiling` in `Execution_Time.Group_Budgets`. See D.14.2(7/2).
- 107.3/3 • The value of `CPU_Range'Last` in `System.Multiprocessors`. See D.16(4/3).
- 107.4/3 • The processor on which the environment task executes in the absence of a value for the aspect CPU. See D.16(13/3).
- 108 • The means for creating and executing distributed programs. See E(5).
- 109 • Any events that can result in a partition becoming inaccessible. See E.1(7).
- 110 • The scheduling policies, treatment of priorities, and management of shared resources between partitions in certain cases. See E.1(11).
- 111/1 • *This paragraph was deleted.*
- 112 • Whether the execution of the remote subprogram is immediately aborted as a result of cancellation. See E.4(13).
- 112.1/2 • The range of type `System.RPC.Partition_Id`. See E.5(14).
- 113/2 • *This paragraph was deleted.*
- 114 • Implementation-defined interfaces in the PCS. See E.5(26).
- 115 • The values of named numbers in the package `Decimal`. See F.2(7).
- 116 • The value of `Max_Picture_Length` in the package `Text_IO.Editing`. See F.3.3(16).

- The value of `Max_Picture_Length` in the package `Wide_Text_IO`.Editing See F.3.4(5). 117
- The value of `Max_Picture_Length` in the package `Wide_Wide_Text_IO`.Editing See F.3.5(5). 117.1/2
- The accuracy actually achieved by the complex elementary functions and by other complex arithmetic operations. See G.1(1). 118
- The sign of a zero result (or a component thereof) from any operator or function in `Numerics.Generic_Complex_Types`, when `Real'Signed_Zeros` is `True`. See G.1.1(53). 119
- The sign of a zero result (or a component thereof) from any operator or function in `Numerics.Generic_Complex_Elementary_Functions`, when `Complex_Types.Real'Signed_Zeros` is `True`. See G.1.2(45). 120
- Whether the strict mode or the relaxed mode is the default. See G.2(2). 121
- The result interval in certain cases of fixed-to-float conversion. See G.2.1(10). 122
- The result of a floating point arithmetic operation in overflow situations, when the `Machine_Overflows` attribute of the result type is `False`. See G.2.1(13). 123
- The result interval for division (or exponentiation by a negative exponent), when the floating point hardware implements division as multiplication by a reciprocal. See G.2.1(16). 124
- The definition of *close result set*, which determines the accuracy of certain fixed point multiplications and divisions. See G.2.3(5). 125
- Conditions on a *universal_real* operand of a fixed point multiplication or division for which the result shall be in the *perfect result set*. See G.2.3(22). 126
- The result of a fixed point arithmetic operation in overflow situations, when the `Machine_Overflows` attribute of the result type is `False`. See G.2.3(27). 127
- The result of an elementary function reference in overflow situations, when the `Machine_Overflows` attribute of the result type is `False`. See G.2.4(4). 128
- The value of the *angle threshold*, within which certain elementary functions, complex arithmetic operations, and complex elementary functions yield results conforming to a maximum relative error bound. See G.2.4(10). 129
- The accuracy of certain elementary functions for parameters beyond the angle threshold. See G.2.4(10). 130
- The result of a complex arithmetic operation or complex elementary function reference in overflow situations, when the `Machine_Overflows` attribute of the corresponding real type is `False`. See G.2.6(5). 131
- The accuracy of certain complex arithmetic operations and certain complex elementary functions for parameters (or components thereof) beyond the angle threshold. See G.2.6(8). 132
- The accuracy requirements for the subprograms `Solve`, `Inverse`, `Determinant`, `Eigenvalues` and `Eigensystem` for type `Real_Matrix`. See G.3.1(81/2). 132.1/2
- The accuracy requirements for the subprograms `Solve`, `Inverse`, `Determinant`, `Eigenvalues` and `Eigensystem` for type `Complex_Matrix`. See G.3.2(149/2). 132.2/2

- *This paragraph was deleted.* 136/2
- Implementation-defined *policy_identifiers* allowed in a `pragma Partition_Elaboration_Policy`. See H.6(4/2). 136.1/2

M.3 Implementation Advice

- 1/2 This International Standard sometimes gives advice about handling certain target machine dependences. Each Ada implementation must document whether that advice is followed:
- 1.a/2 **Ramification:** Some of the items in this list require documentation only for implementations that conform to Specialized Needs Annexes.
- 2/2 • `Program_Error` should be raised when an unsupported Specialized Needs Annex feature is used at run time. See 1.1.3(20).
 - 3/2 • Implementation-defined extensions to the functionality of a language-defined library unit should be provided by adding children to the library unit. See 1.1.3(21).
 - 4/2 • If a bounded error or erroneous execution is detected, `Program_Error` should be raised. See 1.1.5(12).
 - 5/2 • Implementation-defined pragmas should have no semantic effect for error-free programs. See 2.8(16/3).
 - 6/2 • Implementation-defined pragmas should not make an illegal program legal, unless they complete a declaration or configure the `library_items` in an environment. See 2.8(19).
 - 7/2 • `Long_Integer` should be declared in Standard if the target supports 32-bit arithmetic. No other named integer subtypes should be declared in Standard. See 3.5.4(28).
 - 8/2 • For a two's complement target, modular types with a binary modulus up to `System.Max_Int*2+2` should be supported. A nonbinary modulus up to `Integer'Last` should be supported. See 3.5.4(29).
 - 9/2 • `Program_Error` should be raised for the evaluation of `S'Pos` for an enumeration type, if the value of the operand does not correspond to the internal code for any enumeration literal of the type. See 3.5.5(8).
 - 10/2 • `Long_Float` should be declared in Standard if the target supports 11 or more digits of precision. No other named float subtypes should be declared in Standard. See 3.5.7(17).
 - 11/2 • Multidimensional arrays should be represented in row-major order, unless the array has convention `Fortran`. See 3.6.2(11/3).
 - 12/3 • `Tags.Internal_Tag` should return the tag of a type, if one exists, whose innermost master is a master of the point of the function call.. See 3.9(26.1/3).
 - 13/2 • A real static expression with a nonformal type that is not part of a larger static expression should be rounded the same as the target system. See 4.9(38.1/2).
 - 14/2 • The value of `Duration'Small` should be no greater than 100 microseconds. See 9.6(30).
 - 15/2 • The time base for `delay_relative_statements` should be monotonic. See 9.6(31).
 - 16/2 • Leap seconds should be supported if the target system supports them. Otherwise, operations in `Calendar.Formatting` should return results consistent with no leap seconds. See 9.6.1(89/2).
 - 17/2 • When applied to a generic unit, a program unit pragma that is not a library unit pragma should apply to each instance of the generic unit for which there is not an overriding pragma applied directly to the instance. See 10.1.5(10/1).
 - 18/2 • A type declared in a preelaborated package should have the same representation in every elaboration of a given version of the package. See 10.2.1(12).
 - 19/2 • `Exception_Information` should provide information useful for debugging, and should include the `Exception_Name` and `Exception_Message`. See 11.4.1(19).
 - 20/2 • `Exception_Message` by default should be short, provide information useful for debugging, and should not include the `Exception_Name`. See 11.4.1(19).

- Code executed for checks that have been suppressed should be minimized. See 11.5(28). 21/2
- The recommended level of support for all representation items should be followed. See 13.1(28/3). 22/2
- Storage allocated to objects of a packed type should be minimized. See 13.2(6). 23/2
- The recommended level of support for the Pack aspect should be followed. See 13.2(9). 24/3
- For an array *X*, *X'Address* should point at the first component of the array rather than the array bounds. See 13.3(14). 25/2
- The recommended level of support for the Address attribute should be followed. See 13.3(19). 26/2
- For any tagged specific subtype *S*, *S'Class'Alignment* should equal *S'Alignment*. See 13.3(28). 26.1/3
- The recommended level of support for the Alignment attribute should be followed. See 13.3(35). 27/2
- The Size of an array object should not include its bounds. See 13.3(41.1/2). 28/2
- If the Size of a subtype allows for efficient independent addressability, then the Size of most objects of the subtype should equal the Size of the subtype. See 13.3(52). 29/2
- A Size clause on a composite subtype should not affect the internal layout of components. See 13.3(53). 30/2
- The recommended level of support for the Size attribute should be followed. See 13.3(56). 31/2
- The recommended level of support for the Component_Size attribute should be followed. See 13.3(73). 32/2
- The recommended level of support for `enumeration_representation_clauses` should be followed. See 13.4(10). 33/2
- The recommended level of support for `record_representation_clauses` should be followed. See 13.5.1(22). 34/2
- If a component is represented using a pointer to the actual data of the component which is contiguous with the rest of the object, then the storage place attributes should reflect the place of the actual data. If a component is allocated discontinuously from the rest of the object, then a warning should be generated upon reference to one of its storage place attributes. See 13.5.2(5). 35/2
- The recommended level of support for the nondefault bit ordering should be followed. See 13.5.3(8). 36/2
- `Type System.Address` should be a private type. See 13.7(37). 37/2
- Operations in `System` and its children should reflect the target environment; operations that do not make sense should raise `Program_Error`. See 13.7.1(16). 38/2
- Since the Size of an array object generally does not include its bounds, the bounds should not be part of the converted data in an instance of `Unchecked_Conversion`. See 13.9(14/2). 39/2
- There should not be unnecessary run-time checks on the result of an `Unchecked_Conversion`; the result should be returned by reference when possible. Restrictions on `Unchecked_Conversions` should be avoided. See 13.9(15). 40/2
- The recommended level of support for `Unchecked_Conversion` should be followed. See 13.9(17). 41/2
- Any cases in which heap storage is dynamically allocated other than as part of the evaluation of an `allocator` should be documented. See 13.11(23). 42/2
- A default storage pool for an access-to-constant type should not have overhead to support deallocation of individual objects. See 13.11(24). 43/2

- 44/2 • Usually, a storage pool for an access discriminant or access parameter should be created at the point of an `allocator`, and be reclaimed when the designated object becomes inaccessible. For other anonymous access types, the pool should be created at the point where the type is elaborated and need not support deallocation of individual objects. See 13.11(25).
- 45/2 • For a standard storage pool, an instance of `Unchecked_Deallocation` should actually reclaim the storage. See 13.11.2(17).
- 45.1/3 • A call on an instance of `Unchecked_Deallocation` with a nonnull access value should raise `Program_Error` if the actual access type of the instance is a type for which the `Storage_Size` has been specified to be zero or is defined by the language to be zero. See 13.11.2(17.1/3).
- 46/2 • If not specified, the value of `Stream_Size` for an elementary type should be the number of bits that corresponds to the minimum number of stream elements required by the first subtype of the type, rounded up to the nearest factor or multiple of the word size that is also a multiple of the stream element size. See 13.13.2(1.6/2).
- 47/2 • The recommended level of support for the `Stream_Size` attribute should be followed. See 13.13.2(1.8/2).
- 48/2 • If an implementation provides additional named predefined integer types, then the names should end with “Integer”. If an implementation provides additional named predefined floating point types, then the names should end with “Float”. See A.1(52).
- 49/2 • Implementation-defined operations on `Wide_Character`, `Wide_String`, `Wide_Wide_Character`, and `Wide_Wide_String` should be child units of `Wide_Characters` or `Wide_Wide_Characters`. See A.3.1(7/3).
- 49.1/3 • The string returned by `Wide_Characters.Handling.Character_Set_Version` should include either “10646:” or “Unicode”. See A.3.5(62).
- 50/2 • Bounded string objects should not be implemented by implicit pointers and dynamic allocation. See A.4.4(106).
- 51/2 • `Strings.Hash` should be good a hash function, returning a wide spread of values for different string values, and similar strings should rarely return the same value. See A.4.9(12/2).
- 51.1/3 • If an implementation supports other string encoding schemes, a child of `Ada.Strings` similar to `UTF_Encoding` should be defined. See A.4.11(107/3).
- 52/2 • Any storage associated with an object of type `Generator` of the random number packages should be reclaimed on exit from the scope of the object. See A.5.2(46).
- 53/2 • Each value of `Initiator` passed to `Reset` for the random number packages should initiate a distinct sequence of random numbers, or, if that is not possible, be at least a rapidly varying function of the initiator value. See A.5.2(47).
- 54/2 • `Get_Immediate` should be implemented with unbuffered input; input should be available immediately; line-editing should be disabled. See A.10.7(23).
- 55/2 • `Package Directories.Information` should be provided to retrieve other information about a file. See A.16(124/2).
- 56/3 • `Directories.Start_Search` and `Directories.Search` should raise `Name_Error` for malformed patterns. See A.16(125).
- 57/2 • `Directories.Rename` should be supported at least when both `New_Name` and `Old_Name` are simple names and `New_Name` does not identify an existing external file. See A.16(126/2).
- 57.1/3 • `Directories.Hierarchical_File_Names` should be provided for systems with hierarchical file naming, and should not be provided on other systems. See A.16.1(36/3).

- If the execution environment supports subprocesses, the current environment variables should be used to initialize the environment variables of a subprocess. See A.17(32/2). 58/2
- Changes to the environment variables made outside the control of Environment_Variables should be reflected immediately. See A.17(33/2). 59/2
- Containers.Hash_Type'Modulus should be at least 2^{32} . Containers.Count_Type'Last should be at least $2^{31}-1$. See A.18.1(8/2). 60/2
- The worst-case time complexity of Element for Containers.Vector should be $O(\log N)$. See A.18.2(256/2). 61/2
- The worst-case time complexity of Append with Count = 1 when N is less than the capacity for Containers.Vector should be $O(\log N)$. See A.18.2(257/2). 62/2
- The worst-case time complexity of Prepend with Count = 1 and Delete_First with Count=1 for Containers.Vectors should be $O(N \log N)$. See A.18.2(258/2). 63/2
- The worst-case time complexity of a call on procedure Sort of an instance of Containers.Vectors.Generic_Sorting should be $O(N^2)$, and the average time complexity should be better than $O(N^2)$. See A.18.2(259/2). 64/2
- Containers.Vectors.Generic_Sorting.Sort and Containers.Vectors.Generic_Sorting.Merge should minimize copying of elements. See A.18.2(260/2). 65/2
- Containers.Vectors.Move should not copy elements, and should minimize copying of internal data structures. See A.18.2(261/2). 66/2
- If an exception is propagated from a vector operation, no storage should be lost, nor any elements removed from a vector unless specified by the operation. See A.18.2(262/2). 67/2
- The worst-case time complexity of Element, Insert with Count=1, and Delete with Count=1 for Containers.Doubly_Linked_Lists should be $O(\log N)$. See A.18.3(160/2). 68/2
- A call on procedure Sort of an instance of Containers.Doubly_Linked_Lists.Generic_Sorting should have an average time complexity better than $O(N^2)$ and worst case no worse than $O(N^2)$. See A.18.3(161/2). 69/2
- Containers.Doubly_Linked_Lists.Move should not copy elements, and should minimize copying of internal data structures. See A.18.3(162/2). 70/2
- If an exception is propagated from a list operation, no storage should be lost, nor any elements removed from a list unless specified by the operation. See A.18.3(163/2). 71/2
- Move for a map should not copy elements, and should minimize copying of internal data structures. See A.18.4(83/2). 72/2
- If an exception is propagated from a map operation, no storage should be lost, nor any elements removed from a map unless specified by the operation. See A.18.4(84/2). 73/2
- The average time complexity of Element, Insert, Include, Replace, Delete, Exclude and Find operations that take a key parameter for Containers.Hashed_Maps should be $O(\log N)$. The average time complexity of the subprograms of Containers.Hashed_Maps that take a cursor parameter should be $O(1)$. The average time complexity of Containers.Hashed_Maps.Reserve_Capacity should be $O(N)$. See A.18.5(62/2). 74/2
- The worst-case time complexity of Element, Insert, Include, Replace, Delete, Exclude and Find operations that take a key parameter for Containers.Ordered_Maps should be $O((\log N)^2)$ or better. The worst-case time complexity of the subprograms of Containers.Ordered_Maps that take a cursor parameter should be $O(1)$. See A.18.6(95/2). 75/2
- Move for sets should not copy elements, and should minimize copying of internal data structures. See A.18.7(104/2). 76/2

- 77/2 • If an exception is propagated from a set operation, no storage should be lost, nor any elements removed from a set unless specified by the operation. See A.18.7(105/2).
- 78/2 • The average time complexity of the Insert, Include, Replace, Delete, Exclude and Find operations of Containers.Hashing_Sets that take an element parameter should be $O(\log N)$. The average time complexity of the subprograms of Containers.Hashing_Sets that take a cursor parameter should be $O(1)$. The average time complexity of Containers.Hashing_Sets.Reserve_Capacity should be $O(N)$. See A.18.8(88/2).
- 79/2 • The worst-case time complexity of the Insert, Include, Replace, Delete, Exclude and Find operations of Containers.Ordered_Sets that take an element parameter should be $O((\log N)**2)$. The worst-case time complexity of the subprograms of Containers.Ordered_Sets that take a cursor parameter should be $O(1)$. See A.18.9(116/2).
- 79.1/3 • The worst-case time complexity of the Element, Parent, First_Child, Last_Child, Next_Sibling, Previous_Sibling, Insert_Child with Count=1, and Delete operations of Containers.Multiway_Trees should be $O(\log N)$. See A.18.10(231/3).
- 79.2/3 • Containers.Multiway_Trees.Move should not copy elements, and should minimize copying of internal data structures. See A.18.10(232/3).
- 79.3/3 • If an exception is propagated from a tree operation, no storage should be lost, nor any elements removed from a tree unless specified by the operation. See A.18.10(233/3).
- 79.4/3 • Containers.Indefinite_Holders.Move should not copy the element, and should minimize copying of internal data structures. See A.18.18(73/3).
- 79.5/3 • If an exception is propagated from a holder operation, no storage should be lost, nor should the element be removed from a holder container unless specified by the operation. See A.18.18(74/3).
- 79.6/3 • Bounded vector objects should be implemented without implicit pointers or dynamic allocation. See A.18.19(16/3).
- 79.7/3 • The implementation advice for procedure Move to minimize copying does not apply to bounded vectors. See A.18.19(17/3).
- 79.8/3 • Bounded list objects should be implemented without implicit pointers or dynamic allocation. See A.18.20(19/3).
- 79.9/3 • The implementation advice for procedure Move to minimize copying does not apply to bounded lists. See A.18.20(20/3).
- 79.10/3 • Bounded hashed map objects should be implemented without implicit pointers or dynamic allocation. See A.18.21(21/3).
- 79.11/3 • The implementation advice for procedure Move to minimize copying does not apply to bounded hashed maps. See A.18.21(22/3).
- 79.12/3 • Bounded ordered map objects should be implemented without implicit pointers or dynamic allocation. See A.18.22(18/3).
- 79.13/3 • The implementation advice for procedure Move to minimize copying does not apply to bounded ordered maps. See A.18.22(19/3).
- 79.14/3 • Bounded hashed set objects should be implemented without implicit pointers or dynamic allocation. See A.18.23(20/3).
- 79.15/3 • The implementation advice for procedure Move to minimize copying does not apply to bounded hashed sets. See A.18.23(21/3).
- 79.16/3 • Bounded ordered set objects should be implemented without implicit pointers or dynamic allocation. See A.18.24(17/3).

- The implementation advice for procedure `Move` to minimize copying does not apply to bounded ordered sets. See A.18.24(18/3). 79.17/3
- Bounded tree objects should be implemented without implicit pointers or dynamic allocation. See A.18.25(19/3). 79.18/3
- The implementation advice for procedure `Move` to minimize copying does not apply to bounded trees. See A.18.25(20/3). 79.19/3
- `Containers.Generic_Array_Sort` and `Containers.Generic_Constrained_Array_Sort` should have an average time complexity better than $O(N^{**2})$ and worst case no worse than $O(N^{**2})$. See A.18.26(10/2). 80/2
- `Containers.Generic_Array_Sort` and `Containers.Generic_Constrained_Array_Sort` should minimize copying of elements. See A.18.26(11/2). 81/2
- `Containers.Generic_Sort` should have an average time complexity better than $O(N^{**2})$ and worst case no worse than $O(N^{**2})$. See A.18.26(12/3). 81.1/3
- `Containers.Generic_Sort` should minimize calls to the generic formal `Swap`. See A.18.26(13/3). 81.2/3
- Bounded queue objects should be implemented without implicit pointers or dynamic allocation. See A.18.29(13/3). 81.3/3
- Bounded priority queue objects should be implemented without implicit pointers or dynamic allocation. See A.18.31(14/3). 81.4/3
- If `Export` is supported for a language, the main program should be able to be written in that language. Subprograms named "adainit" and "adafinal" should be provided for elaboration and finalization of the environment task. See B.1(39/3). 82/3
- Automatic elaboration of preelaborated packages should be provided when specifying the `Export` aspect as `True` is supported. See B.1(40/3). 83/3
- For each supported convention L other than `Intrinsic`, specifying the aspects `Import` and `Export` should be supported for objects of L -compatible types and for subprograms, and aspect `Convention` should be supported for L -eligible types and for subprograms. See B.1(41/3). 84/3
- If an interface to C, COBOL, or Fortran is provided, the corresponding package or packages described in Annex B, "Interface to Other Languages" should also be provided. See B.2(13/3). 85/2
- The constants `nul`, `wide_nul`, `char16_nul`, and `char32_nul` in package `Interfaces.C` should have a representation of zero. See B.3(62.5/3). 86/2
- If C interfacing is supported, the interface correspondences between Ada and C should be supported. See B.3(71). 87/2
- If COBOL interfacing is supported, the interface correspondences between Ada and COBOL should be supported. See B.4(98). 88/2
- If Fortran interfacing is supported, the interface correspondences between Ada and Fortran should be supported. See B.5(26). 89/2
- The machine code or intrinsics support should allow access to all operations normally available to assembly language programmers for the target environment. See C.1(3). 90/2
- Interface to assembler should be supported; the default assembler should be associated with the convention identifier `Assembler`. See C.1(4/3). 91/2
- If an entity is exported to assembly language, then the implementation should allocate it at an addressable location even if not otherwise referenced from the Ada code. A call to a machine code or assembler subprogram should be treated as if it could read or update every object that is specified as exported. See C.1(5). 92/2

- 93/2 • Little or no overhead should be associated with calling intrinsic and machine-code subprograms. See C.1(10).
- 94/2 • Intrinsic subprograms should be provided to access any machine operations that provide special capabilities or efficiency not normally available. See C.1(16).
- 95/2 • If the `Ceiling_Locking` policy is not in effect and the target system allows for finer-grained control of interrupt blocking, a means for the application to specify which interrupts are to be blocked during protected actions should be provided. See C.3(28/2).
- 96/2 • Interrupt handlers should be called directly by the hardware. See C.3.1(20).
- 97/2 • Violations of any implementation-defined restrictions on interrupt handlers should be detected before run time. See C.3.1(21).
- 98/2 • If implementation-defined forms of interrupt handler procedures are supported, then for each such form of a handler, a type analogous to `Parameterless_Handler` should be specified in a child package of `Interrupts`, with the same operations as in the predefined package `Interrupts`. See C.3.2(25).
- 99/2 • Preelaborated packages should be implemented such that little or no code is executed at run time for the elaboration of entities. See C.4(14).
- 100/2 • If `pragma Discard_Names` applies to an entity, then the amount of storage used for storing names associated with that entity should be reduced. See C.5(8).
- 101/2 • A load or store of a volatile object whose size is a multiple of `System.Storage_Unit` and whose alignment is nonzero, should be implemented by accessing exactly the bits of the object and no others. See C.6(22/2).
- 102/2 • A load or store of an atomic object should be implemented by a single load or store instruction. See C.6(23/2).
- 103/2 • If the target domain requires deterministic memory use at run time, storage for task attributes should be pre-allocated statically and the number of attributes pre-allocated should be documented. See C.7.2(30).
- 104/2 • Finalization of task attributes and reclamation of associated storage should be performed as soon as possible after task termination. See C.7.2(30.1/2).
- 105/2 • Names that end with “`_Locking`” should be used for implementation-defined locking policies. See D.3(17).
- 106/2 • Names that end with “`_Queuing`” should be used for implementation-defined queuing policies. See D.4(16).
- 107/2 • The `abort_statement` should not require the task executing the statement to block. See D.6(9).
- 108/2 • On a multi-processor, the delay associated with aborting a task on another processor should be bounded. See D.6(10).
- 109/2 • When feasible, specified restrictions should be used to produce a more efficient implementation. See D.7(21).
- 110/2 • When appropriate, mechanisms to change the value of `Tick` should be provided. See D.8(47).
- 111/2 • `Calendar.Clock` and `Real_Time.Clock` should be transformations of the same time base. See D.8(48).
- 112/2 • The “best” time base which exists in the underlying system should be available to the application through `Real_Time.Clock`. See D.8(49).
- 112.1/3 • On a multiprocessor system, each processor should have a separate and disjoint ready queue. See D.13(9).

- When appropriate, implementations should provide configuration mechanisms to change the value of `Execution_Time.CPU_Tick`. See D.14(29/2). 113/2
- For a timing event, the handler should be executed directly by the real-time clock interrupt mechanism. See D.15(25). 114/2
- Each dispatching domain should have separate and disjoint ready queues. See D.16.1(31). 114.1/3
- The PCS should allow for multiple tasks to call the RPC-receiver. See E.5(28). 115/2
- The `System.RPC.Write` operation should raise `Storage_Error` if it runs out of space when writing an item. See E.5(29). 116/2
- If COBOL (respectively, C) is supported in the target environment, then interfacing to COBOL (respectively, C) should be supported as specified in Annex B. See F(7/3). 117/2
- Packed decimal should be used as the internal representation for objects of subtype *S* when `S'Machine_Radix = 10`. See F.1(2). 118/2
- If Fortran (respectively, C) is supported in the target environment, then interfacing to Fortran (respectively, C) should be supported as specified in Annex B. See G(7/3). 119/2
- Mixed real and complex operations (as well as pure-imaginary and complex operations) should not be performed by converting the real (resp. pure-imaginary) operand to complex. See G.1.1(56). 120/2
- If `Real'Signed_Zeros` is True for `Numerics.Generic_Complex_Types`, a rational treatment of the signs of zero results and result components should be provided. See G.1.1(58). 121/3
- If `Complex_Types.Real'Signed_Zeros` is True for `Numerics.Generic_Complex_Elementary_Functions`, a rational treatment of the signs of zero results and result components should be provided. See G.1.2(49). 122/3
- For elementary functions, the forward trigonometric functions without a `Cycle` parameter should not be implemented by calling the corresponding version with a `Cycle` parameter. `Log` without a `Base` parameter should not be implemented by calling `Log` with a `Base` parameter. See G.2.4(19). 123/2
- For complex arithmetic, the `Compose_From_Polar` function without a `Cycle` parameter should not be implemented by calling `Compose_From_Polar` with a `Cycle` parameter. See G.2.6(15). 124/2
- `Solve` and `Inverse` for `Numerics.Generic_Real_Arrays` should be implemented using established techniques such as LU decomposition and the result should be refined by an iteration on the residuals. See G.3.1(88/3). 125/2
- The equality operator should be used to test that a matrix in `Numerics.Generic_Real_Arrays` is symmetric. See G.3.1(90/2). 126/2
- An implementation should minimize the circumstances under which the algorithm used for `Numerics.Generic_Real_Arrays.Eigenvalues` and `Numerics.Generic_Real_Arrays.Eigensystem` fails to converge. See G.3.1(91/3). 126.1/3
- `Solve` and `Inverse` for `Numerics.Generic_Complex_Arrays` should be implemented using established techniques and the result should be refined by an iteration on the residuals. See G.3.2(158/3). 127/2
- The equality and negation operators should be used to test that a matrix is Hermitian. See G.3.2(160/2). 128/2
- An implementation should minimize the circumstances under which the algorithm used for `Numerics.Generic_Complex_Arrays.Eigenvalues` and `Numerics.Generic_Complex_Arrays.Eigensystem` fails to converge. See G.3.2(160.1/3). 128.1/3
- Mixed real and complex operations should not be performed by converting the real operand to complex. See G.3.2(161/2). 129/2

- 130/2 • The information produced by `pragma Reviewable` should be provided in both a human-readable and machine-readable form, and the latter form should be documented. See H.3.1(19).
- 131/2 • Object code listings should be provided both in a symbolic format and in a numeric format. See H.3.1(20).
- 132/3 • If the partition elaboration policy is `Sequential` and the `Environment` task becomes permanently blocked during elaboration, then the partition should be immediately terminated. See H.6(15/3).

Annex N

(informative)

Glossary

- {AI95-00437-01}* This Annex contains informal descriptions of some of the terms used in this International Standard. The index provides references to more formal definitions of all of the terms used in this International Standard. 1/2
- Abstract type.** An abstract type is a tagged type intended for use as an ancestor of other types, but which is not allowed to have objects of its own. 1.1/2
- Access type.** An access type has values that designate aliased objects. Access types correspond to “pointer types” or “reference types” in some other languages. 2
- Aliased.** An aliased view of an object is one that can be designated by an access value. Objects allocated by allocators are aliased. Objects can also be explicitly declared as aliased with the reserved word **aliased**. The Access attribute can be used to create an access value designating an aliased object. 3
- Ancestor.** An ancestor of a type is the type itself or, in the case of a type derived from other types, its parent type or one of its progenitor types or one of their ancestors. Note that ancestor and descendant are inverse relationships. 3.1/2
- Array type.** An array type is a composite type whose components are all of the same type. Components are selected by indexing. 4
- Aspect.** An aspect is a specifiable property of an entity. An aspect may be specified by an `aspect_specification` on the declaration of the entity. Some aspects may be queried via attributes. 4.1/3
- Assertion.** An assertion is a boolean expression that appears in any of the following: a `pragma Assert`, a predicate, a precondition, a postcondition, an invariant, a constraint, or a null exclusion. An assertion is expected to be True at run time at certain specified places. 4.2/3
- Category (of types).** A category of types is a set of types with one or more common properties, such as primitive operations. A category of types that is closed under derivation is also known as a *class*. 4.3/2
- Character type.** A character type is an enumeration type whose values include characters. 5
- Class (of types).** A class is a set of types that is closed under derivation, which means that if a given type is in the class, then all types derived from that type are also in the class. The set of types of a class share common properties, such as their primitive operations. 6/2
- Compilation unit.** The text of a program can be submitted to the compiler in one or more compilations. Each compilation is a succession of `compilation_units`. A `compilation_unit` contains either the declaration, the body, or a renaming of a program unit. 7
- Composite type.** A composite type may have components. 8/2
- Construct.** A *construct* is a piece of text (explicit or implicit) that is an instance of a syntactic category defined under “Syntax”. 9
- Container.** A container is an object that contain other objects all of the same type, which could be class-wide. Several predefined container types are provided by the children of package `Ada.Containers` (see A.18.1). 9.1/3
- Controlled type.** A controlled type supports user-defined assignment and finalization. Objects are always finalized before being destroyed. 10

- 11 **Declaration.** A *declaration* is a language construct that associates a name with (a view of) an entity. A declaration may appear explicitly in the program text (an *explicit* declaration), or may be supposed to occur at a given place in the text as a consequence of the semantics of another construct (an *implicit* declaration).
- 12/2 *This paragraph was deleted.*
- 13/2 **Derived type.** A derived type is a type defined in terms of one or more other types given in a derived type definition. The first of those types is the parent type of the derived type and any others are progenitor types. Each class containing the parent type or a progenitor type also contains the derived type. The derived type inherits properties such as components and primitive operations from the parent and progenitors. A type together with the types derived from it (directly or indirectly) form a derivation class.
- 13.1/2 **Descendant.** A type is a descendant of itself, its parent and progenitor types, and their ancestors. Note that descendant and ancestor are inverse relationships.
- 14 **Discrete type.** A discrete type is either an integer type or an enumeration type. Discrete types may be used, for example, in `case` statements and as array indices.
- 15/2 **Discriminant.** A discriminant is a parameter for a composite type. It can control, for example, the bounds of a component of the type if the component is an array. A discriminant for a task type can be used to pass data to a task of the type upon creation.
- 15.1/2 **Elaboration.** The process by which a declaration achieves its run-time effect is called elaboration. Elaboration is one of the forms of execution.
- 16 **Elementary type.** An elementary type does not have components.
- 17 **Enumeration type.** An enumeration type is defined by an enumeration of its values, which may be named by identifiers or character literals.
- 17.1/2 **Evaluation.** The process by which an expression achieves its run-time effect is called evaluation. Evaluation is one of the forms of execution.
- 18 **Exception.** An *exception* represents a kind of exceptional situation; an occurrence of such a situation (at run time) is called an *exception occurrence*. To *raise* an exception is to abandon normal program execution so as to draw attention to the fact that the corresponding situation has arisen. Performing some actions in response to the arising of an exception is called *handling* the exception.
- 19 **Execution.** The process by which a construct achieves its run-time effect is called *execution*. Execution of a declaration is also called *elaboration*. Execution of an expression is also called *evaluation*.
- 19.1/2 **Function.** A function is a form of subprogram that returns a result and can be called as part of an expression.
- 20 **Generic unit.** A generic unit is a template for a (nongeneric) program unit; the template can be parameterized by objects, types, subprograms, and packages. An instance of a generic unit is created by a `generic_instantiation`. The rules of the language are enforced when a generic unit is compiled, using a generic contract model; additional checks are performed upon instantiation to verify the contract is met. That is, the declaration of a generic unit represents a contract between the body of the generic and instances of the generic. Generic units can be used to perform the role that macros sometimes play in other languages.
- 20.1/2 **Incomplete type.** An incomplete type gives a view of a type that reveals only some of its properties. The remaining properties are provided by the full view given elsewhere. Incomplete types can be used for defining recursive data structures.

- Indexable container type.** An indexable container type is one that has user-defined behavior for indexing, via the `Constant_Indexing` or `Variable_Indexing` aspects. 20.2/3
- Integer type.** Integer types comprise the signed integer types and the modular types. A signed integer type has a base range that includes both positive and negative numbers, and has operations that may raise an exception when the result is outside the base range. A modular type has a base range whose lower bound is zero, and has operations with “wraparound” semantics. Modular types subsume what are called “unsigned types” in some other languages. 21
- Interface type.** An interface type is a form of abstract tagged type which has no components or concrete operations except possibly null procedures. Interface types are used for composing other interfaces and tagged types and thereby provide multiple inheritance. Only an interface type can be used as a progenitor of another type. 21.1/2
- Invariant.** A invariant is an assertion that is expected to be True for all objects of a given private type when viewed from outside the defining package. 21.2/3
- Iterable container type.** An iterable container type is one that has user-defined behavior for iteration, via the `Default_Iterator` and `Iterator_Element` aspects. 21.3/3
- Iterator.** An iterator is a construct that is used to loop over the elements of an array or container. Iterators may be user defined, and may perform arbitrary computations to access elements from a container. 21.4/3
- Library unit.** A library unit is a separately compiled program unit, and is always a package, subprogram, or generic unit. Library units may have other (logically nested) library units as children, and may have other program units physically nested within them. A root library unit, together with its children and grandchildren and so on, form a *subsystem*. 22
- Limited type.** A limited type is a type for which copying (such as in an `assignment_statement`) is not allowed. A nonlimited type is a type for which copying is allowed. 23/2
- Object.** An object is either a constant or a variable. An object contains a value. An object is created by an `object_declaration` or by an `allocator`. A formal parameter is (a view of) an object. A subcomponent of an object is an object. 24
- Overriding operation.** An overriding operation is one that replaces an inherited primitive operation. Operations may be marked explicitly as overriding or not overriding. 24.1/2
- Package.** Packages are program units that allow the specification of groups of logically related entities. Typically, a package contains the declaration of a type (often a private type or private extension) along with the declarations of primitive subprograms of the type, which can be called from outside the package, while their inner workings remain hidden from outside users. 25
- Parent.** The parent of a derived type is the first type given in the definition of the derived type. The parent can be almost any kind of type, including an interface type. 25.1/2
- Partition.** A *partition* is a part of a program. Each partition consists of a set of library units. Each partition may run in a separate address space, possibly on a separate computer. A program may contain just one partition. A distributed program typically contains multiple partitions, which can execute concurrently. 26
- Postcondition.** A postcondition is an assertion that is expected to be True when a given subprogram returns normally. 26.1/3
- Pragma.** A pragma is a compiler directive. There are language-defined pragmas that give instructions for optimization, listing control, etc. An implementation may support additional (implementation-defined) pragmas. 27

- 27.1/3 **Precondition.** A precondition is an assertion that is expected to be True when a given subprogram is called.
- 27.2/3 **Predicate.** A predicate is an assertion that is expected to be True for all objects of a given subtype.
- 28 **Primitive operations.** The primitive operations of a type are the operations (such as subprograms) declared together with the type declaration. They are inherited by other types in the same class of types. For a tagged type, the primitive subprograms are dispatching subprograms, providing run-time polymorphism. A dispatching subprogram may be called with statically tagged operands, in which case the subprogram body invoked is determined at compile time. Alternatively, a dispatching subprogram may be called using a dispatching call, in which case the subprogram body invoked is determined at run time.
- 29/2 **Private extension.** A private extension is a type that extends another type, with the additional properties hidden from its clients.
- 30/2 **Private type.** A private type gives a view of a type that reveals only some of its properties. The remaining properties are provided by the full view given elsewhere. Private types can be used for defining abstractions that hide unnecessary details from their clients.
- 30.1/2 **Procedure.** A procedure is a form of subprogram that does not return a result and can only be called by a statement.
- 30.2/2 **Progenitor.** A progenitor of a derived type is one of the types given in the definition of the derived type other than the first. A progenitor is always an interface type. Interfaces, tasks, and protected types may also have progenitors.
- 31 **Program.** A *program* is a set of *partitions*, each of which may execute in a separate address space, possibly on a separate computer. A partition consists of a set of library units.
- 32 **Program unit.** A *program unit* is either a package, a task unit, a protected unit, a protected entry, a generic unit, or an explicitly declared subprogram other than an enumeration literal. Certain kinds of program units can be separately compiled. Alternatively, they can appear physically nested within other program units.
- 33/2 **Protected type.** A protected type is a composite type whose components are accessible only through one of its protected operations which synchronize concurrent access by multiple tasks.
- 34 **Real type.** A real type has values that are approximations of the real numbers. Floating point and fixed point types are real types.
- 35 **Record extension.** A record extension is a type that extends another type by adding additional components.
- 36 **Record type.** A record type is a composite type consisting of zero or more named components, possibly of different types.
- 36.1/3 **Reference type.** A reference type is one that has user-defined behavior for “.all”, defined by the `Implicit_Dereference` aspect.
- 36.2/2 **Renaming.** A `renaming_declaration` is a declaration that does not define a new entity, but instead defines a view of an existing entity.
- 37 **Scalar type.** A scalar type is either a discrete type or a real type.
- 37.1/3 **Storage pool.** Each access-to-object type has an associated storage pool object. The storage for an object created by an `allocator` comes from the storage pool of the type of the `allocator`. Some storage pools may be partitioned into subpools in order to support finer-grained storage management.

- Stream.** A stream is a sequence of elements that can be used, along with the stream-oriented attributes, to support marshalling and unmarshalling of values of most types. 37.2/3
- Subprogram.** A subprogram is a section of a program that can be executed in various contexts. It is invoked by a subprogram call that may qualify the effect of the subprogram through the passing of parameters. There are two forms of subprograms: functions, which return values, and procedures, which do not. 37.3/2
- Subtype.** A subtype is a type together with optional constraints, null exclusions, and predicates, which constrain the values of the subtype to satisfy certain conditions. The values of a subtype are a subset of the values of its type. 38/3
- Synchronized.** A synchronized entity is one that will work safely with multiple tasks at one time. A synchronized interface can be an ancestor of a task or a protected type. Such a task or protected type is called a synchronized tagged type. 38.1/2
- Tagged type.** The objects of a tagged type have a run-time type tag, which indicates the specific type with which the object was originally created. An operand of a class-wide tagged type can be used in a dispatching call; the tag indicates which subprogram body to invoke. Nondispatching calls, in which the subprogram body to invoke is determined at compile time, are also allowed. Tagged types may be extended with additional components. 39
- Task type.** A task type is a composite type used to represent active entities which execute concurrently and which can communicate via queued task entries. The top-level task of a partition is called the environment task. 40/2
- Type.** Each object has a type. A *type* has an associated set of values, and a set of *primitive operations* which implement the fundamental aspects of its semantics. Types are grouped into *categories*. Most language-defined categories of types are also *classes* of types. 41/2
- View.** A view of an entity reveals some or all of the properties of the entity. A single entity may have multiple views. 42/2

Annex P

(informative)

Syntax Summary

This Annex summarizes the complete syntax of the language. See 1.1.4 for a description of the notation used.

```

2.3:
identifier ::=
  identifier_start {identifier_start | identifier_extend}

2.3:
identifier_start ::=
  letter_uppercase
| letter_lowercase
| letter_titlecase
| letter_modifier
| letter_other
| number_letter

2.3:
identifier_extend ::=
  mark_non_spacing
| mark_spacing_combining
| number_decimal
| punctuation_connector

2.4:
numeric_literal ::= decimal_literal | based_literal

2.4.1:
decimal_literal ::= numeral [.numeral] [exponent]

2.4.1:
numeral ::= digit {[underline] digit}

2.4.1:
exponent ::= E [+] numeral | E - numeral

2.4.1:
digit ::= 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9

2.4.2:
based_literal ::=
  base # based_numeral [.based_numeral] # [exponent]

2.4.2:
base ::= numeral

2.4.2:
based_numeral ::=
  extended_digit {[underline] extended_digit}

2.4.2:
extended_digit ::= digit | A | B | C | D | E | F

2.5:
character_literal ::= 'graphic_character'

2.6:
string_literal ::= "{string_element}"

2.6:
string_element ::= "" | non_quotation_mark_graphic_character

2.7:
comment ::= --{non_end_of_line_character}

2.8:
pragma ::=

```

pragma identifier [(pragma_argument_association {, pragma_argument_association})];

2.8:

pragma_argument_association ::=
 | *pragma_argument_identifier* =>] name
 | *pragma_argument_identifier* =>] expression
 | *pragma_argument_aspect_mark* => name
 | *pragma_argument_aspect_mark* => expression

3.1:

basic_declaration ::=
 | type_declaration | subtype_declaration
 | object_declaration | number_declaration
 | subprogram_declaration | abstract_subprogram_declaration
 | null_procedure_declaration | expression_function_declaration
 | package_declaration | renaming_declaration
 | exception_declaration | generic_declaration
 | generic_instantiation

3.1:

defining_identifier ::= identifier

3.2.1:

type_declaration ::= full_type_declaration
 | incomplete_type_declaration
 | private_type_declaration
 | private_extension_declaration

3.2.1:

full_type_declaration ::=
type defining_identifier [known_discriminant_part] **is** type_definition
 [aspect_specification];
 | task_type_declaration
 | protected_type_declaration

3.2.1:

type_definition ::=
 enumeration_type_definition | integer_type_definition
 | real_type_definition | array_type_definition
 | record_type_definition | access_type_definition
 | derived_type_definition | interface_type_definition

3.2.2:

subtype_declaration ::=
subtype defining_identifier **is** subtype_indication
 [aspect_specification];

3.2.2:

subtype_indication ::= [null_exclusion] subtype_mark [constraint]

3.2.2:

subtype_mark ::= *subtype_name*

3.2.2:

constraint ::= scalar_constraint | composite_constraint

3.2.2:

scalar_constraint ::=
 range_constraint | digits_constraint | delta_constraint

3.2.2:

composite_constraint ::=
 index_constraint | discriminant_constraint

3.3.1:

object_declaration ::=
 defining_identifier_list : [**aliased**] [**constant**] subtype_indication [:= expression]
 [aspect_specification];
 | defining_identifier_list : [**aliased**] [**constant**] access_definition [:= expression]
 [aspect_specification];
 | defining_identifier_list : [**aliased**] [**constant**] array_type_definition [:= expression]

```

    [aspect_specification];
| single_task_declaration
| single_protected_declaration
3.3.1:
defining_identifier_list ::=
    defining_identifier {, defining_identifier}
3.3.2:
number_declaration ::=
    defining_identifier_list : constant := static_expression;
3.4:
derived_type_definition ::=
    [abstract] [limited] new parent_subtype_indication [[and interface_list] record_extension_part]
3.5:
range_constraint ::= range range
3.5:
range ::= range_attribute_reference
| simple_expression .. simple_expression
3.5.1:
enumeration_type_definition ::=
    (enumeration_literal_specification {, enumeration_literal_specification})
3.5.1:
enumeration_literal_specification ::= defining_identifier | defining_character_literal
3.5.1:
defining_character_literal ::= character_literal
3.5.4:
integer_type_definition ::= signed_integer_type_definition | modular_type_definition
3.5.4:
signed_integer_type_definition ::= range static_simple_expression .. static_simple_expression
3.5.4:
modular_type_definition ::= mod static_expression
3.5.6:
real_type_definition ::=
    floating_point_definition | fixed_point_definition
3.5.7:
floating_point_definition ::=
    digits static_expression [real_range_specification]
3.5.7:
real_range_specification ::=
    range static_simple_expression .. static_simple_expression
3.5.9:
fixed_point_definition ::= ordinary_fixed_point_definition | decimal_fixed_point_definition
3.5.9:
ordinary_fixed_point_definition ::=
    delta static_expression real_range_specification
3.5.9:
decimal_fixed_point_definition ::=
    delta static_expression digits static_expression [real_range_specification]
3.5.9:
digits_constraint ::=
    digits static_expression [range_constraint]
3.6:
array_type_definition ::=
    unconstrained_array_definition | constrained_array_definition
3.6:
unconstrained_array_definition ::=

```

```

array(index_subtype_definition {, index_subtype_definition}) of component_definition
3.6:
index_subtype_definition ::= subtype_mark range <>
3.6:
constrained_array_definition ::=
  array (discrete_subtype_definition {, discrete_subtype_definition}) of component_definition
3.6:
discrete_subtype_definition ::= discrete_subtype_indication | range
3.6:
component_definition ::=
  [aliased] subtype_indication
  | [aliased] access_definition
3.6.1:
index_constraint ::= (discrete_range {, discrete_range})
3.6.1:
discrete_range ::= discrete_subtype_indication | range
3.7:
discriminant_part ::= unknown_discriminant_part | known_discriminant_part
3.7:
unknown_discriminant_part ::= (<>)
3.7:
known_discriminant_part ::=
  (discriminant_specification {; discriminant_specification})
3.7:
discriminant_specification ::=
  defining_identifier_list : [null_exclusion] subtype_mark [:= default_expression]
  | defining_identifier_list : access_definition [:= default_expression]
3.7:
default_expression ::= expression
3.7.1:
discriminant_constraint ::=
  (discriminant_association {, discriminant_association})
3.7.1:
discriminant_association ::=
  [discriminant_selector_name { | discriminant_selector_name} =>] expression
3.8:
record_type_definition ::= [[abstract] tagged] [limited] record_definition
3.8:
record_definition ::=
  record
    component_list
  end record
  | null record
3.8:
component_list ::=
  component_item {component_item}
  | {component_item} variant_part
  | null;
3.8:
component_item ::= component_declaration | aspect_clause
3.8:
component_declaration ::=
  defining_identifier_list : component_definition [:= default_expression]
  [aspect_specification];
3.8.1:
variant_part ::=

```

```

case discriminant_direct_name is
  variant
  {variant}
end case;
3.8.1:
variant ::=
  when discrete_choice_list =>
    component_list
3.8.1:
discrete_choice_list ::= discrete_choice { | discrete_choice }
3.8.1:
discrete_choice ::= choice_expression | discrete_subtype_indication | range | others
3.9.1:
record_extension_part ::= with record_definition
3.9.3:
abstract_subprogram_declaration ::=
  [overriding_indicator]
  subprogram_specification is abstract
  [aspect_specification];
3.9.4:
interface_type_definition ::=
  [limited | task | protected | synchronized] interface [and interface_list]
3.9.4:
interface_list ::= interface_subtype_mark { and interface_subtype_mark }
3.10:
access_type_definition ::=
  [null_exclusion] access_to_object_definition
  | [null_exclusion] access_to_subprogram_definition
3.10:
access_to_object_definition ::=
  access [general_access_modifier] subtype_indication
3.10:
general_access_modifier ::= all | constant
3.10:
access_to_subprogram_definition ::=
  access [protected] procedure parameter_profile
  | access [protected] function parameter_and_result_profile
3.10:
null_exclusion ::= not null
3.10:
access_definition ::=
  [null_exclusion] access [constant] subtype_mark
  | [null_exclusion] access [protected] procedure parameter_profile
  | [null_exclusion] access [protected] function parameter_and_result_profile
3.10.1:
incomplete_type_declaration ::= type defining_identifier [discriminant_part] [is tagged];
3.11:
declarative_part ::= { declarative_item }
3.11:
declarative_item ::=
  basic_declarative_item | body
3.11:
basic_declarative_item ::=
  basic_declaration | aspect_clause | use_clause
3.11:
body ::= proper_body | body_stub

```

```

3.11:

Syntax Cross Reference

{AI05-0299-1} In the following syntax cross reference, each syntactic category is followed by the subclause number where it is defined. In addition, each syntactic category *S* is followed by a list of the categories that use *S* in their definitions. For example, the first listing below shows that `abort_statement` appears in the definition of `simple_statement`.

<code>abort_statement</code>	9.8	<code>array_type_definition</code>	3.6
<code>simple_statement</code>	5.1	<code>formal_array_type_definition</code>	12.5.3
<code>abortable_part</code>	9.7.4	<code>object_declaration</code>	3.3.1
<code>asynchronous_select</code>	9.7.4	<code>type_definition</code>	3.2.1
<code>abstract_subprogram_declaration</code>	3.9.3	<code>aspect_clause</code>	13.1
<code>basic_declaration</code>	3.1	<code>basic_declarative_item</code>	3.1.1
<code>accept_alternative</code>	9.7.1	<code>component_item</code>	3.8

Annex Q

(informative)

Language-Defined Entities

{AI95-00440-01} This annex lists the language-defined entities of the language. A list of language-defined library units can be found in Annex A, “Predefined Language Environment”. 1/2

Q.1 Language-Defined Packages

{AI95-00440-01} {AI05-0299-1} This subclause lists all language-defined packages. 1/3

Q.5 Language-Defined Objects

{AI95-00440-01} {AI05-0299-1} This subclause lists all language-defined constants, variables, named numbers, and enumeration literals. 1/3

To be honest: Formally, named numbers and enumeration literals aren't objects, but it was thought to be too weird to say “Language-Defined Objects and Values”. 1.a/2
